The range man who is a producer of beef, appreciates good sires and invariably has them, but the small farmer who runs only a few cows cannot afford a good beef sire, and consequently uses any kind of a sire he can get. The results are a lot of hit-and-miss calves that bring the lowest prices. To overcome this condition there should be co-operation in the purchase and use of good sires. By this arrangement every farmer can have the use of a good sire at a very nominal cost.

The use of boars and rams comes in for the same consideration. It is a mistake to use an untried boar or ram once and then get rid of him. His value as in individual and breeder can be determined only after he has been developed, and the character of his offspring determined. When he is owned by a signle farmer the cost of keep is so high and there is so much labor required in his care that the farmer gets rid of him after one season. When the sire is owned co-operatively the reverse is true, and he can be retained as long as desired at a low cost to the co-operators.

Co-operative ownership of sires is one eof the big questions that confront the farmers, and it should have their most careful consideration.

Better sires mean better animals and greater profit. With high prices of feed the best is none too good.

LOUDEN

Quality Service

Hay Season is Short—Hay Crop is Valuable

A day's delay or a sudden storm in haying may mean a heavy loss. Wherever hay must be handled quickly and economically you can depend on

LOUDEN HAY TOOLS

Honestly built—simple—sturdy construction—stronger than your work will ever demand—safety first—use good judgment.

LOUDEN EQUIPMENT IS A PROFITABLE INVESTMENT, NOT AN EXPENSE

You will be surprised how little really high grade equipment costs. Send us lengths of your mow, whether centre drive or end unloading and width space between rafters. Can furnish slings, grapple, or harpoon fork at your option.

BITTERNESS IN CREAM

Bitterness in cream and milk is a frequent trouble during the winter months. If the mlk is bitter when it is drawn, the trouble is with the cow or her feed. Very often cows give bitter milk toward the close or their lactation period. The old dry weeds of winter pasture also give rise to a bitter flavor in milk. The remedy in this case is to keep the cow from such pastures.

However, if bitterness develops after the milk is drawn, which is most often the case in winter, it is due to the growth in it of certain variety of bacteria. These bacteria get into milk usually from pieces of dirit or manure from the barn. At low temperatures they will develop a bitter flavor before the milk or cream sours. When the dairy is once infested with such bacteria they may remain in the separator, pails, strainers or colling tank for a long time. To prevent bitterness due to this cause, these bacteria must be eliminated. This means that all utensils, separator parts, strainers and cooling tank must be thoroughly washed and scalded. All dirt should be kept out of the pail at milking time by keeping the can clean and using a pail with a small opening.

While making such a clean-up the trouble might be prevented by addinig some sour milk to the cream as soon as separated and keeping it in a warm place until the batch is sour. Then it can be cooled and kept till churning time. Sour cream seldom turns bitter unless kept several days.

CREOSOTE DRIP IN THE CHIMNEY

My chimney is plastered on the inside but not the outside. There is some brown water that comes out between the bricks from the roof and down six feet. Last year I was troubled the same way, so I built a new chimney, and now it is worse than ever. Could you tell me what I should do for it? J. C.

Reply: Most troubles with chimneys are caused by defective draft. The purpose of a chimney is to carry away the waste gases of combustion. To enable it to do this, some heat must be discharged into the chimney so that the column of air and other gases contained in it is expanded and by this expansion made lighter, hence rising and flowing out at the top, being replaced during the meantime with other gases flowing in at the bottom. Practically the only force then causing an upward flow in a chimney is the difference in weight between the somewhat heated column of air in the chimney flue and the colder surrounding outside air. To get the fullest effects of this force certain conditions must be met.

The chimney should be tight, so that air cannot be taken into it at any point without first passing through the burning material on the grate, or at such other points as may be regulated to control the draft and resulting combustion. It should be about 30 feet high, and should extend to a point about two feet above the highest part of the roof by the most direct route possible. It should extend above the roof to permit the wind to blow straight across the top, and not subject it to eddy currents that frequently blow down the flue and cause the puffs of smoke and gas sometimes seen coming from a stove in wind weather, and should be as straight as conditions will permit, to get rid of offsets that serve as places for soot and ashes to pile up, obstructing the draft. Sometimes an obstructed draft is caused by a pipe being thrust too far into the chimney, so that there is very little opening for the smoke to come form the end of the pipe. All of the conditions mentioned, if not as they should be, tend to lessen the heat in a chimney because the air current is made slower and less heated air is discharged through the flue in a given time. Even in a perfect chimney the draft may be so controlled by dampers thta practically the same effect is obtained, and this is often the case in the effort which everyone makes to conserve fuel.

When wood is burned there are certain liquids that are discharged into the chimney as gases, but which, if the temperature is permitted to get too low from any of the causes mentioned, are condensed on the inside of the flue surface and form the brown liquid mentioned. This may also be caused in an outside chimney where the walls are unprotected. Burning certain kinds of wood, as beech or green woods of any variety, makes this trouble much worse. Sometimes storm water will beat into the top of the chimney and cause some trouble from the resulting solution of ashes, etc., that seeps down. The indicated remedy seems to be to first see that the flue is so constructed that it meets all of the requirements, and if found to be right in this respect so to control the drafts that the air in the chimney is kept warm enough to prevent condensation. In some cases where the trouble is very bad and the creosote extends back into the pipe, the pipe is put together backward and given a slope toward the stove, so that any liquid discharged into it will find its way back to the stove.

Let This Engine Save Money on Your Farm

Money saved in labor means greater profits on production. That is the purpose of the "Z" Engine on your farm. It means work done quicker, better and at less cost than by the old methods.

A 6, 3 or 1½ Horse Power

"Z" Engine

does its work day and night at the lowest upkeep cost because of its simplicity of construction and its fuel economy. No matter for what purpose you want power on your farm investigate the "Z" first—the engine that meets the farmer's needs.

Your local dealer can tell you about the "Z". He sells it; he is the direct representative of the manufacturer and he, personally, stands behind each engine he sells to see that the purchaser gets the fullest satisfaction. Ask your dealer or write today to our nearest office.

MANAGING THE HERD BULL

Watch the Quiet, Gentle Fellow

It always seems to be the gentle bull that attacks its caretaker and causes serious injury or death. A bull that is known to be ugly is watched, and as the attendant is on guard when around the animal there is less danger of injury.

It never pays to allow a bull to find out its strength, and for this reason the farmer should keep control of the animal at all times and not let it know that the strength of the boss is inferior to its own physical powers.

There is much risk in allowing bulls to go down in the pasture with the cows, especially if the fences are not in the best of condition. Frequently a bull has broken out and gone down the road, where it has caused much trouble and possibly a serious loss to some farmer owning a purebred herd of another breed. There is also the danger that the bull will injure people on the road, and after once obtaining its freedom, it is more difficult to control the animal and keep it contented while in confinement.

The best method of managing the bull is to keep him in a strongly built box stall, with a small yard outside, where he can exercise and see the other members of the herd. The fence around the yard should be well built and braced. Strong cement posts with iron pipe set in the cement connecting the posts makes an unbreakable pen. If a stout board fence is used, do not make the boards so high that the bull cannot see what is going on outside.

A sire that is not at least one year old is too young for breeding, and the first year that the animal is used for breeding, the amount of service should be limited. Because a bull seems strong and vigorous is no reason why its breeding powers should not be protected as carefully as is the case with other kinds of farm animals.

All bulls should be dehorned. This is a protection for the care-taker, and in addition the bull without horns is less apt to develop a pugnacious disposition. The bull should always be ringed, and led with a staff, and if it is exercised by driving or using on a tread mill, the greatest care must be taken to avoid injury to men working around the animal.

When we consider what a poor sire

HORSES, COWS, HOGS and all other farm animals will be in better health if given

=OMAZON=

CANADIAN MEDICINAL FOOD

Gives appetite, promotes digestion, prevents disease, removes Worms and cures Indigestion, Constipation, Colic, Diarrhœa, etc.

3

can do to a good dairy herd and what a good sire can do for a poor herd, it is evident that more consideration should be given to the dairy bull. When every farmer realizes how much cash is thrown away by accepting services from scrub bulls, the dairy business will become more profitable, breeding fees will be paid with less grumbling, and all dairy organizations will grow more rapidly.

WAY TO PAINT METAL SURFACES

Any person who has found it necessary to purchase any farm machinery, tin or galvanized roofing or other metal materials within the last year or two has paid a much higher price than formerly. The increased cost of articles manufactured from metal makes it imperative that they be made to last as long as possible. Painting farm machinery not only prevents rust, but improves the appearance and makes the implements work much more easily.

Tin roofing and eaves spouting, if not kept painted, will soon rust through. Iron posts and fences are much improved in appearance if painted. Farm machinery, as mentioned above, will give better service, and it is more economical to wear a machine out than to allow it to rust out. Besides, machinery that is kept painted will nearly always bring a higher price, whether sold at private or public sale.

Before painting metals, the surface must be thoroughly cleaned. All dirt and rust should be removed. It will often be necessary to scrape the metal down to the bare surface before painting. Iron brushes or scrapers can be used for this purpose. Frequently machinery will be covered with oil or grease. This must be removed and the surface allowed to dry before one is ready to apply the paint. If one slights this preparation, in a short time the paint will likely crack and peel off. If the surface is rusty, steel wire brushes about 2 inches wide and 6 inches long may be purchased and will be found useful in removing the rust.

Most any person can apply the paint himself and do a reasonably good job. A brush should be selected that is suitable for the kind of work for which it is to be used. In painting roofs, a flat brush will cover more surface than an oval one. However, on other work a round brush will probably prove more satisfactory. The surface should be dry and the paint rubbed in thoroughly.

The painting can be done at a time when the farmer is not rushed with other work. The implements may be painted in some clean, well-lighted building that is free from dust. One should not attempt to paint roofing, spouting, fences and gates in a rainy time or the paint will not dry.

As to paint, some good paint of known reputation should be used. It does not pay to buy paint of which you know nothing because it is cheaper than some well-known, reliable, advertised brand. Purchase the best paint, apply two or three coats, rubbing them in well if you wish to have a first-class job. F. R.

All the YEAR through let your Property be **PAINT** *Protected*

WHEN the thermometer registers "90 in the shade" a blistering sun attacks the poorly-painted building. In zero weather, ice and snow damage the property that is not paint-protected. Between seasons there is wind, rain and sleet to contend against. Your property will *not* successfully resist the attacks of severe storms or scorching sun rays, unless given that kind of protection which only a quality paint can guarantee.

It's Better to **PAINT** *than* **REPAIR**

B-H "ENGLISH" PAINT 70% Pure White Lead (Brandram's Genuine B.B.) 30% Pure White Zinc 100% Pure Paint

Making our own white lead and linseed oil, we *know*, and therefore can guarantee that all the basic ingredients of B-H "English" Paint are such as to ensure complete and lasting protection for any building to which it is applied.

The only correct formula for an outdoor paint is the one calling for 70 per cent pure white lead and 30 per cent pure white zinc. That formula we print on every can of B-H, together with our guarantee that this high standard is maintained.

Before you paint anything be sure you are using the right kind of paint, and giving your surface the correct preparation.

Other B-H Products We are proud to sell

For Interior Finishing, "China Lac" the perfect varnish stain.
Staining the Roof, B-H Shingle Stain in 19 different colors.
B-H Porch Floor Paint For porch floors, ceilings and parts exposed to the weather.
Plaster Ceilings and Walls B-H "Fresconette"—A flat tone oil paint.
Finishing a Floor, B-H "Floor Lustre," excellent for interior floors.
For Barns and Outbuildings Imperial Barn Paint.

REASONS FOR USING PURE-BRED BULLS

The secretary of the Wisconsin Breeders' Association, gives these seven reasons why he has used only purebred bulls:

Because it pays. Everyone knows that good producers pay better than poor producers, and to get more profitable cows means to use purebred sires.

Because I like to work with good tools. When a man chops, he wants a good sharp axe. When driving an engine or team he wants one that is right and responds to fuel or feed, levers or lines. So with cows, We want them to respond to feed and care, and to ensure this they must be bred for the purpose. That means purebred sires.

Because I like to see and own the best animals possible. When we set out trees to beautify our homes we select the most perfect in every way. When we plant flowers we choose the most beautiful. We are always striving towards perfection. In the same way it is always my pleasure and satisfaction to see, own, and handle the most perfect specimens of live stock, the most beautiful in form and most perfect in function. These do not come by accident, but only through the use of the best purebred sires.

Because I want to help build up my community. It is said that he who makes "two blades of grass grow where only one grew before" is truly a philanthropist, but not any more so than he who makes one blade of grass do the work of two by feeding better cows. This man is an asset in every way to his community. He becomes a better citizen, and adds prestige to his business. But he does not accomplish this by using a scrub bull and being a scrub man.

Because it gives the whole family more interest in the farm and home. There is inspiration for everyone in building up a good herd. Better care is taken of the cows. Every heifer calf is an interesting study as to what she will develop into and why. Instead of looking forward only to hard work we now are eager for what the future will bring and work with interest for best results because of better bulls.

Because I am proud to belong in the "purebred class," where you find better homes and higher ideals because of better bulls.

Because all other reasons aside, I would be ashamed to use a scrub bull and thereby advertise the fact that I belonged in the "scrub class," the more so since it is so easy to get out of this class by using a better bull.

TREATING INFESTED CHICKEN HOUSES

The first step necessary to destroy mites is to get rid of the hiding places so far as possible. The roosts should be taken down and all unnecessary boards and boxes removed. In heavily infested houses the mites are to be found in all parts of the building, including the roor. Where they are less numerous the infestations usually are confined to the roosts and nests and the wall immediately adjecent. For small coops a hand atomizer will suffice for applying insecticides as spraps, but for larger houses a bucket pump, knapsack sprayer, or barrel is desirable. A rather coarse spray should be applied from all angles and thoroughly driven into the cracks. The floor also should be treated, as many mites fal to the floor when the roosts are being removed.

Top Dress with Nitrate of Soda

It does not Sour the Soil

Nitrate of Soda leaves no mineral acid residue behind to injure your soil. It makes bigger crops—and keeps the land sweet.

Nitrate of Soda

Top dress 100 lbs. per acre for seeded crops; 200 lbs. cultivated in thoroughly for cultivated crops. These light dressings, evenly spread over an acre, will work for your profit.

MARKETS.

COUNTRY PRODUCE

Montreal, May 3.—The feature of the egg situation today was the large offerings from country points for shipment at 46c per dozen, f.o.b., which buyers in cases were not disposed to pay, as mos tof them have large supplies rolling, and the impressions of some in the trade was that the feeling, if anything, was inclined to be easier.

There was a fairly good demand for suplies for domestic consumption today, and prices were unchanged, with sales in a jobbing way at 49c to 50c per dozen. The receipts were 4,272 cases, as against 3,9666 for the same day last week, and 4,751 for the corresponding date a year ago.

There was no change in the conditio nof the market for beans, business being still quiet and prices unchanged, with broken lots of Ontario handpicked quoted at $3.50 to $3.75, and car lots at $3.25 per bushel, and Quebec beans at $2.50 to $3. There is a steady demand for small lots of peas, and sales of choice boiling stock were made at $3.25 to $3.50, nd Quebec peas at $2.50 to $3 per bushel.

A firm feeling prevailed in the market for maple product on account of the continued small receipts and the light supplies available on spot, for which thre is a fair demand, and sales were made at $2.25 per tin of 13 lbs., and at $1.80 to $1.85 per tin of 8½ lbs., while maple sugar sold at 52c lb.

There was no further development in the market for potatoes today, but the tone of the market is very firm owing to the continued small supplies coming forward, for which there is a good demand, and sales of car lots of Quebec white were made at $1.90 to $2 per bag of 90 lbs. ex-track, and at $2.15 to $2.25 per bag of 90 lbs. in a jobbing way ex-store.

The tone of the market for dressed poultry remains very firm under a continued good demand for supplies for local consumption and outside account, and a fairy active trade was done, including sales of some fair-sized lots for shipment to outside points. There is no scarcity of stock yet, but supplies are being steadily reduced, and with the movement for export the prospects are that there will be a shortage of some lines in the near future.

We quote wholesale prices of cold storage poultry as follow.:

Choice turkeys, per lb.	48c to 50c
Milk-fed chickens	45c to 47c
Ordinary chickens	40c to 43c
Fowle, heavy	37c to 38c
Fowls, light	33c to 34c
Ducks, No. 1	42c to 44c
Ducks, No. 2	40c to 41c
Geese	31c to 32c

DAIRY PRODUCE TRADE

Montreal, May 3.—The receipts of butter today were 714 packages, as against 414 for the same day last week, and 1,074 for the corresponding date a year ago. At Gould's Cold Storage today the first sale for the season 1919 was held, when 200 packages creamery butter were offered, and all sold at 55c to 56c per lb., f.o.b. country points, as to quality. Owing to the steady increase in the receipts, and the prospects of them being much larger in the near future, an easy feeling continues to prevail in the market, and in consequence the demand from local buyers is limited, and only for small lots to meet actual wants and sales in a wholesale way of finest creamery were made today at 57c per lb. The demand for oleomargerine continues good, and a fairly active trade was done in a jobbing way at 34c to 35c per lb. in 1-lb.. blocks, and at 33ct to 34c in tubs.

We quote wholesale jobbing prices as follows:

Finest creamery, solids	60c
Finest creamery, blocks	61c
Fine creamery, solids	59c

The receipts of cheese today were 521 boxes, as compared with 961 for the same day last week and 2,157 for the corresponding date a year ago. At Gould's Cold Storage today the offering amounted to 500 boxes, which consisted principally of white goods, and al lsold at 23½c per lb., f.o.b., country points. A private cable was received today from a leading house in London by a local merchant asking for cheese prices, the condition of the market and the propects for the make for the season 1919.

THE PROVISION MARKET

Montreal, May 3.—A very firm feeling prevails in the local market for live hogs owing to the continued good demand and the small offerings, and prices were unchanged, with sales of selected lots at $22.25 to $22.50 per 100 lbs. weighed off cars, and lots weighing les than 140 lbs. each at $20.25 to $20.50. The demand for dressed hogs showed no improvement, and the trade ewas rather quiet, but as suplies were small prices ruled firm, with sales of city abattoir fresh-killed stock in a jobbing way at $30.50 to $31 per 100 lbs.

The condition of the market for smoked and cured meats was unihanged, the feeling being firm, with only a small trade passing for local and country account, and the market o nthe whole was rather quiet, with sales of 8 to 10-lb. hams at 40c per lb., 12 to 15 lbs. at 38c to 39c, and heavier weigrts at 36c to 37c, while breakfast bacon sold at 44c to 45c. Windsor selected bacon at 47c to 48c, and Windsor bone less bacon at 49c to 50c.

A good steady trade continues to be done in lard in a jobing way, and the market is fairly active with a firm undertone, and sales of Canadian pure leaf grades were made at 33c per lb. in 20-lb. wood pails, and at 34c per lb. in 1-lb. blocks. The receipts of provisions today were 975 packages lard, 23 boxes hams and bacon and 407 packages tinned meats.

THE LOCAL GRAIN MARKET

Montreal, May 3.—The weakness developed in the option grain markets yesterday was decidedly more pronounced today and prices had a severe break, corn in Chicago closing 10⅜c to 11¼c per bushel lower and oats 2⅝c to 3⅛c while in the Winnipeg market barley sold 3⅛c off and oats 3⅛c. In sympathy with the above a weaker feeling also prevailed in the local market for cash grain, and prices for barley were reduced 1c per bushel, and oats 1½c. The trade was very quiet, the demand beinb still imitel, and only odd cars to meet immediate wants, and sales of

You Get More Work with a Cleveland

Buy a tractor that will do more than plow.

Buy a tractor—for faster, less-man-power, less-horse-power, more profitable farming.

But buy a tractor that will—disc, harrow, seed.

Without soiling the seed-bed.

Buy the Cleveland Tractor.

Lay its own track as it travels. Pressure only 5 pounds to the square inch. Less than a man walking. CAN'T pack the plowed ground. CAN'T wallow in soft ground. WILL work over rough ground, hilly ground, gullies. And uses less fuel doing this because it rides on top WITHOUT SLIPPAGE.

And will harvest, thresh, haul loads, cut feed and ensilage, operate machinery—work more days in the year.

The Cleveland Tractor is the product of a giant organization embracing engineering, genius and manufacturing facilities of the highest type. That is why the Cleveand operates successfully on kerosene (coal oil) uses no more kerosene than other tractors use gasoline. That is why the Cleveland stands up to its work day in and day out, year after year. That is why the Cleveland is an investment, not an expense.

Most farmers plow 10 acres a day with a Cleveland—saves 9 horses and 2 men.

Use double discs, two 60 tooth harrows, and heavy wooden drag for fitting—40 acres a day.

And every month in the year those Cleveland owners have their tractor at work.

Of course it pays for itself. Your nearest Cleveland dealer can show you how. Write to us for our interesting booklet, "Our Owners Say," giving actual experiences with Cleveland Tractors.

R. R. No. 5, Belleville, Ont.
The Cleveland Tractor Company of Canada, Ltd.
Windsor, Ont.

Gentlemen :—

I have been operating my Cleveland Tractor for over three months, doing all my Fall plowing discing, cultivating, etc., using three 10" bottom plows, with excellent results, on clay land which is more or less stony.

I have had it operating a 13" Gilson ensilage cutter on a 36-foot silo with like results, and was surprised at the simplicity in lining up this little machine for belt-work —I use no bracing.

Before purchasing, I attended the Cobourg demonstration, where I carefully looked over all tractors on the grounds, and finally decided on the Cleveland on quality of construction, simplicity and principle.

And, Brother Farmer, I am at your service any time you care to come to my farm and see this little boss doing the work quicker and better than it has ever been done before.

(Signed) JOHN M. BOYD.

The Cleveland Tractor of Canada, Limited,
Windsor, Ontario

Cleveland Tractor

No. 2 Ontario barley were made at $1.24, extra No. 3 at $1.22, No. 3 at $1.21, No. 3 Canadian western at $1.22 and sample grades at $1.13, while No. 2 Canadian western oats sold at 87c, No. 3 C. W. and extra No. 1 feed at 84c, No. 1 feed at 82c and No. 2 feed at 79c per bushel ex-store.

THE LOCAL FLOUR MARKET

Montreal, May 3.—A fair amount of business continues to be done in spring wheat flour for domestic and country account, and this coupled with the orders on hand at present for export is keeping the mills fully employedfi and the market on the whole is fairly active with no change in prices to note. Sales of car lots of Government standard grade for shipment to country points were made at $11 per barrel in jute bags, ex-track, Montreal freights, and to city bakers at $11 ex-track, or at $11.10 delivered, with broken lots selling to city bakers at $11.00, ex-track, and to grocers and other dealers at $11.20, ex-track, all less 10c per barrel for spot cash. The condition of the market for winter wheat flour was unchanged, prices being firm with sales of broken lots at $10.30 to $10.40 per barrel in new cotton bags, and at $10 in second-hand jute bags, ex-store. The demand for white corn flour is quiet at $8.50 to $9, and rye flour at $8.30 to $8.50 per barrel bags, delivered to the trade.

MILLFEED AND ROLLED OATS

Montreal, May 3.—The market for millfeed continues fairly active under a steady demand for supplies which ar emore plentiful now on account of the increased production of late and buyers find no difficulty in filling their requirements, and there is a good steady movement with no chanbe in prices to note. Sales of broken lots of feed cornmeal were made at $64 mixed grain mollie at $58 to $60, pure barley meal at $56 to $58, mixed moullie at $50 to $52, dairy feed at $46, and oat middlings at $44 per ton, including bags, delivered to the trade, while car lots of bran changed hands at $44 and shorts at $45 to $46 per ton, including bags, ex-track. The trade in rolled oats continues quiet and prices were unchanged with broken lots of standard grades quoted at $3.50 t o$4 per bag of 90 lbs. and Golden cornmeal sold at $4.50 to $4.75 per bag, delivered to the trade.

THE BALED HAY MARKET

Montreal, May 3.—There were no further developments in the market for baled hay today, but the feeling is still very strong on account of the very limited suplies available on spot and sales of car lots of No. 2 timothy hay were made today for local consumption at $31 to $32 per ton, ex-track, and it was reported that this grade of hay has also sold at $30 per ton extrack, f.o.b. country points for shipment, but the Government has not yet made any further advance in prices. No. 1 timothy hay being quoted at $30, No. 1 light clover mixed hay at $30, No. 2 timothy hay at $29, No. 1 clover mixed hay at $28, and No. 3 timothy hay at $27.50 per ton, extrack.

NITRO-CULTURES FOR THE LEGUMES

Among the forage, cover and soiling crops in Canada, one family of plants is of special interest to farmers. These are are legumes or Leguminosae, which include clover and vetches, beans and peas. Botanically they are remarkable for their high nitrogen-yielding qualities, as being constantly associated with bacteria in the soil.

These bacteria-minute living organisms only visible under high microscopic power—form colonies living on the smaller rootlets of the legumes, and produces thereon small lumps of nodules varying in size from a pin head to a small pea. Each kind of crop, whether clover, alfalfa, pet, etc., is greatly benefited by its own particular strain of bacteria culture.

When these bacteria are present in the soil, experience shows that growth is more vigorous, and earlier development takes place. These factors are important in Canada. With alfalfa, robust and early stands have a better chance of resisting winter killing; and in the case of field peas reports from the Western Provinces show increased yields per acre from the use of nitro-cultures.

Where a crop has once been successfully raised with nodules on the roots, the bacteria survive in the soil for some time and a subsequent crop is more easily obtained. To give a crop the best chonce of succesding, the appropriate strain of bacteria should be introduced into the ground.

This can be done by transferring soil from ground where that crop has succeeded, and scattering it broadcast over the new field. This method is laborious and expensive, and besides often introduces undesirable weeds and the germs of diseases. Equally good results have been obtained by using pure bacterial cultures. The method of procedure is to mix the culture material, on which are millions of bacteria, with some fluid, generally skim milk. Then empty the seed on to a clean floor or cloth, and treat it with the fluid, thoroughly stirring the seeds, so that a film of moisture with its bacteria may stick to each seed. The seeds are then spread to dry, out of direct sunlight, which would kill the bacetria. When dry, and on the same day as treated, the seed should be sown and covered up. A cloudy day is the best for this purpose.

Cultures may be obtained commercialy from seedsmen, or Agricultural Colleges, at charges ranging from 25 cents upwards.

The best time for cows to freshen is in the fall, acocrding to many authorities. The weather is then cool, flies are not troublesome, pastures are no longer a factor, and during the winter months the percentage of fat in the milk is at its highest point. The calves can be given more attention during the fall and the young calves can do their best during cool weather.

Get Bigger Hay Crops

Your hay crop can be a pleasure to harvest and a good money-maker if you have efficient hay-making equipment.

Frost & Wood "Champion" Side Delivery Rake

Use a "Champion" and command top market price.

It gathers up the hay into long, loose fluffy windrows where it can cure uniformly. The hay doesn't burn and discolor—nor lose succulence and market value. The "Champion" has 3 tooth bars arranged on a cylinder which gives a steady, rolling motion to the hay until it gets to the windrow. Two castor wheels support the rear end and stop all "digging in" by the teeth. Light draft—very strong—and anyone who can drive can use it.

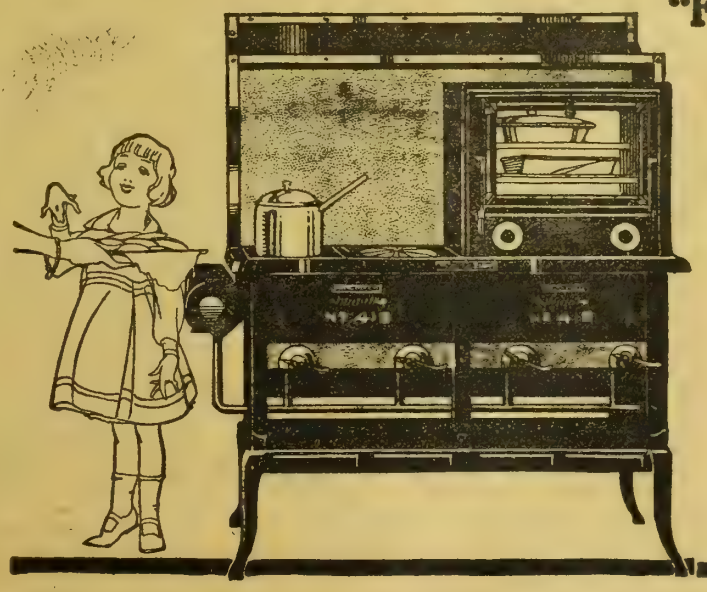
Frost & Wood "Champion" Hay Loader

It's a pleasure to see it pick up the long windrows clean and just as fast as you care to handle the hay—and all the work going where it ought to—on the machine. The "Champion" is very simple—6 tooth bars set in a drum gather the hay and lift it on to a rope-and-slat apron which raises it to the wagon. The whole is operated directly by pawls in the wheels, and thrown in and out of gear by two small levers. Proper design—splendid materials—splendid service.

Let us send you new Hay-making Folder — just drop us a card, or see our nearest Agent.

THE FROST & WOOD COMPANY, LIMITED

Truro ST. JOHN, N. B. Charlottetown



"FLORENCE AUTOMATIC" OIL COOK STOVES

THE blue flame from the Florence wickless burner is always steady, always under perfect control. A special jacket holds it directly under the cooking utensils—**giving a quicker, more economical heat.**

Used with McClary's Success oven, the Florence Automatic is a wonderful baker.

There are no wicks to clean, no odors, no trouble. Let us give you a demonstration of the Florence Automatic in actual operation.

Full information about the Florence oil stoves will be sent free to any address upon request to our nearest branch office.

CULTURE AND SOIL FOR GOOSEBERRIES

Gooseberries may be propagated by hard wood cuttings in the same manner as currants, though they are much more difficult to root. The easiest method is by layering, in fact it is very common to find trailing branches which have been partially covered in cultivation striking root.

Nurserymen usually practice stool layering. This consists of cutting off the entire top of the bush in the fall or spring. This causes the production of a number of vigorous new shoots. When the wood of these begins to harden near the baes of the shoot, earth is heaped about them, causing them to strike root.

Gooseberries prefer a rich, deep, mellow soil. The soil should be well supplied with humus and be deeply plowed and well fitted. The plants should be set as early in the spring as it is possible to properly fit the soil, as they are among the first plants to start in the spring.

The usual distance is 4 by 6 feet. In commercial plantations thorough shallow cultivation is practiced but in the home garden mulching may often be advantageously employed. Stable manure is an excellent fetrilizer since it maintains the humus as well as the fertility.

Gooseberries do not require severe pruning but are benefited by removing the old, broken or diseased canes. There are three gooseberry troubles which may become serious.

The currant worm, by its habit of first attacking the lower leaves and those on the inside of the bush, often causes considerable defoliation before the attack is noticed. Three pounds of arsenate of lead to fifty gallons of water as a spray readily controls this pest, and if one makes the practice, at the time of making the first codling moth spray on apples, to apply the same mixture to the currant and gooseberry bushes, getting the spray all through the bushes, the worms may be ignored. In case the injury is unnoticed until the fruit is well grown use hellebore, dusted on or in a spray at the rate of one ounce to two gallons of water.

The mildew, which attacks the English varieties, and the anthracnose, from which no varieties seem entirely immune, are the two most serious diseases. For the former spraying with potassium sulphide, one pound to fifty gallons of water, is recommended, while the anthracnose may be prevented by keeping the foliage well covered with Bordeaux (4-4-50) or lime sulphur (1-40).

A Correct Lubricant for every Farm Machine
For Gasoline Engines, Tractor, Auto or Stationary
POLARINE OIL
STANDARD GAS ENGINE OIL
For Kerosene Engines Tractor or Stationary
POLARINE OIL HEAVY
POLARINE OIL A
IMPERIAL KEROSENE RACTOR OIL
IMPERIAL KEROSENE TRACTOR OIL EXTRA HEAVY
(Recommended by many tractor manufacturers)
For Open Bearings of Farm Machinery
PRAIRIE HARVESTER OIL
—very heavy body, resists cold, won't thin out with moisture
ELDORADO CASTOR OIL
—a thick oil for worn and loose bearings
For Steam Cylinder Lubrication, whether Tractor or Stationary Type.
CAPITOL CYLINDER OIL
—the standard product for steam cylinder lubrication
THRESHER HARD OIL
For Grease Cup Lubrication of Bearings, a clean solidified oil high melting point.
Successful Farmers are Well Posted on Lubrication
The fellows who are making the most money are usually the ones who have studied the question of lubrication, as well as other farm problems. A thorough knowledge of lubrication is worth hundreds of dollars per year on every Canadian farm.
You cannot expect service from your automobile, if it is poorly lubricated. Your tractor is poor property without proper lubrication. The two machines are unlike in structure and duties, and one kind of oil will not do for both. Be sure that you are using the oils and greases best suited for each machine and each moving part of your farm machinery.
From Imperial Farm Lubricants you can select the right oil for every purpose. All are high grade reliable products. All are correctly refined, from carefully selected crudes. All Imperial Farm Lubricants are made in Canada.
Imperial Farm Lubricants are put up in convenient sizes; one-half, one and four-gallon sealed cans, half barrels and barrels.
IMPERIAL OIL SERVICE
Our service is far more than the mere selling of our products. It follows our products to their work and insures as far as we can insure it, that each Imperial Product does the work for which it is bought. Ask the Imperial Oil man. There is one near you. His service is free and should be valuable.

RENEWING THE OLD APPLE TREES

Old apple trees frequently grow skyward until they reach a height that makes them difficult to harvest. Apple pickers cannot afford to waste their time trying to gather fruit from small limbs which shoot far beyond them when working from the last safe round of the ladder. It pays to dehorn many trees of this type. At least they should be headed back so that all of the fruit can be reached without excessive effort. Then the strength of the trees will be conserved for the lower limbs and they will produce more fruit and fruit of better quality.

The open-centre is of value in the old apple tree to allow the sunshine to enter and color up the fruit. Trees which have a brush-like centre are difficult to spray and harvest and the fruit may be dull and green because of a lack of sunshine. Many old apple orchards have reached a stage where most of the trees cannot be made profitable even with the best of care. It will pay to cut down such trees and plant a new orchard or use the land for another purpose. It is good to recommend the proper care of old orchards, but some of them have reached a stage where they cannot profitably compete with new commercial orchards, and farmers cannot afford to waste time caring for half-dead trees. When the trees are good enough to rejuvenate the low-head and open-centre should be emphasized in training them.

BEST BREED OF POULTRY

"Can you tell me what breed of poultry is best, which are the best layers a and which breed growy the largest?"—Subscriber.

There is probably no best breed of poultry. It is more a matter of strain. There are good and bad strains in all breeds. For general purpose, that is for both the production of eggs and meat, the Plymouth Rocks or Wyandottes or breeds of that type will be found satisfactory, but for straight egg production nothing is better than the Wite Leghorns. The Brahma is the heaviest bird in the Standard but they are slower to develop than some of the other breeds. For a large roaster, it is hard to beat the Plymouth rock.—G. R.

SEX CONTROL

Is it possible to breed cows so that they will produce heifer calves?—C.B.

Reply.—Preponderanace of scientific evidence goes to show that there is no sure way of controlling sex. Breeders have been studying this subject for years and many theories have been advanced but when they have been tried they have been found wanting. This is one of the secrets that nature has never divulged. It is probably wel lthat this is so, for if man had absolute knowledge of the influences that control sex it might be a detriment to the live stock industry instead of a benefit.

LEARN TO CASTRATE THE RAM LAMBS

It seems to be a prevailing habit with sheep growers in many sections to neglect the castration of ram lambs. The local buyer encourages this neglect by paying the same price for the rams as he does for the wether lambs. but he pays the market price for ram lambs rather than that of wether lambs, so he comes out all right, because the inferior grade fixes the price of all and a premium seems to be offered for neglect, when in reality the better grades are dropped to the lowest level of price. But this is not all; the ram lambs in the flock are restless and will not make as good growth as the wethers, so there is a loss in weight by neglecting to use the knife.

The lambs should be castrated when they are from three to four weeks old. if the weather is favorable, though the work should not be done when it is stormy. Some persons do not castrate the lambs because they fear loss from death. but there is practically no danger of a lamb dying from castration if the work is done properly. A clean sharp knife should be used and at least one-third of the scrotum should be cut off. This is necessary to prevent the wound from closing up before it gets well. The cords of the testicles should be well drawn out and cut off.

If the wound should close up prematurely it will inflame and the lamb will get stiff and droopy. This should be watched carefully and in such cases the wound should be opened up so that any pus which may form will drain out of the wound. A little spirits of turpentine dropped about the wound will do no harm and will prevent flies from bothering the lambs if the days are warm. A. J. L.

Major Features in the Feeding of Dairy Cattle

An Address by E.S. Archibald, B.S.A. Director of Experimental Farms, Ottawa

Mr. Chairman, ladies and gentlemen:

I assure you that it gives me a great deal of pleasure to be again at your Convention, and I only regret that I was unable to attend all your meetings, for I have been greatly interested in the progress which you are making and, I have no doubt, have made, particularly during the past few days. It has always appeared to me that these conventions are really your meeeting and that any lengthy addresses on technnical subjects are more or less out of place. This is your business session and I have no doubt that you have had a particularly busy and successful business session.

I was introduced as a professor and as being in charge of the Government farm at Ottawa, and although I do not wish to make any corrections or in any way dispute the chairman of your meeting, yet I think it is perhaps fair to you as an audience to realize just what your Experimental Farm system is, and is attempting to do. The Federal Experimental Farm system is composed of the central farm at Ottawa and twenty-nine branch farms and stations scattered all over Canada. These are experimental farms. We are not professors. We are just your farmers. Our primary object is to investigate the needs in all phases of agriculture for your benefit. We want to keep in touch with you and we expect you to make the best use of your farms. Remember that you, the people of Canada, have requested and demanded these farms, have established them, and we are trying to operate them as you would have them operated for your own benefit. If we do not know your Province if we are not explaining and investigating the agricultural problems as you would desire, I think probably as much blame is yours as ours. I feel that you do not know our exjerimental farms; you do not know our organizations. Perhaps you do not realize our difficulties and you do not place your problems before us just as freely as would be in the best interests of you, the farmers of the Province of New Brunswick.

I am very glad to note that pou are going to the Experimental Farm at Doak to morrow and I know that you who have been out there before will see some very appreciable changes, improvements, advances, particularly in the live stock, which you can see very well at this season of the year.

I was asked to speak a few words tonighton the subject of feeding of dairy cattle and this is such a big subject that I scarcely know just where to begin. However, I will try to touch on a few of what I consider the major features in the feeding of dairy cattle, and I would solicit you to ask any question or bring up any problems which are peculiar to your conditions and which might possibly assist me in handling this rather large and difficult subject. I understand that you have starts with the feeding of the cow five or six months before the calf is bred. The feeding of the dairy cow is the most important step in the production of cheap milk, in the production of good, strong, vigorous calves, in the production of calves with the constitution and thrift to be the kind that mature early and prdouce strongly. We have actually proven in our experimental work with dry cows, that cows deserve the dry period at least four weeks; that the dry cow properly fed—I mean fed liberally on good rich roughage, on good grass, put in really good condition, fairly fed in other words—will produce from 40 to 50% more milk in the year succeeding the actatio nperio, than the cow that is starved and ill fed, the cow that run against the cow shed. Durbeen discussing the question of the eradication of the scrub stock. It seems to me that better food will do more to eradicate scrubby animals, male and female, than anything else you can do . I quite appreciate the value of good breeding and the value of the good sire as compared with the poor sire, but there is one thing that is absolutely certain, that you can make the very best bred calf into one of the best scrubs you can possibly imagine by poor feed, and you can make a fairly poor bred calf into a reaosnably good calf by good feeding. Good feeding and rearing is the climax of good breeding. It is the superfeeding cannot be too strongly emphasized. I would like you to get that matter clearly in mind and if there is structure. It is the finish. Good any dispute on the subject, let us have it.

The feeding of dairy cattle really ing the dry period and until she freshens, take off only a small amount of milk at the start and dry off gradually in your lactation period. More than that, if there is one time in the period of milk production when you can influence the feed test it is just during that dry period. The cow that is dried and is fattened will in the first ten or twelve weeks produce considerably richer milk than the cow that is thin when she freshens. I hold in brief that good fattening of the dairy cow is profitable. It is profitable in increased milk production, in considerably increased fat production, and in much stronger and more vigorous calves. Our method of handling dry cows is simply this. Our average cow produces milk about ten months in the year. If se is a very persistent producer we try to dry her off two months before freshening. As a rule our cows are freshened in the fall. As a rule we find that our freshened cows will produce more milk in a year and taken year in and year out a cheaper milk. Of course the cheapest milk per pound is made on grass. Our cows are dried if necessary forcibly by the cutting off of the ensilage rations. We cut them down to one milking a day, or one milking in two or three days. Then we proceed to feed a good cheap roughage ration. If they are fall freshened and if after grass is cut we make that grass the bulk of the rations and we supplement that with what grain is required. If it is later on and the cow is in the barn during the dry period we depend altogether for our rations on either ensligae or roots or a combination. I prefer roots for the dry cow or for our freshened cows, to any other one food.

Cheap roughage is the basis of cheap milk production. Cheap roughage for you, to my knowledge, would be clover hay, roots and I believe some ensilage either of corn, if you happen to be able to raise corn, or peas, oats, or possibly a mixture of peas, oats and vetches. All of these have shown excellent results and we have been testing them for the past ten or eleven years. In addition to that we feed grain. We have actually proven that a bag of grain fed to a dry cow isequivalent in equal milk production to two or three bags of grain after the cow has freshened. It is a greater stimulant towards heavy production than any amount of good feeding after the cow has freshened can equal.

The grain mixture which we use is a cheap and as much home grown as possible. We prefer oats and barley with some bran as the basis. If we have clover hay we add some oil cake. We prefer however not getting the cow too dry so we supply 8 or 9 pounds of milk per day to dry cows. That may seem expensive, but we have actually proven that if the cow be of the kind that we have to forcibly dry that that 8 or 10 pounds that we have to use is a profitable investment. More than that, we find that our calves are very much more vigorous, are stronger and they get ahead by a very much better start,

This result of our observation and tests after all only goes to prove the practise which our very best dairy farmers have adopted for the last fifteen or twenty years. We can actually produce figures in most instances to prove the desirability of this practise.

The care of the cows at calving is another very important step in the feed for cheap milk. After the cow has freshened we leave her alone, give her a warm drink and leave her alone for twelve hours, and then feed her thin bran or a thin bran and oats slop, preferably warm, three times a day for the first two days. If it is in summer and there is sufficient grass we probably cut some grass for her the first day and let her out not earlier than the second day. We never milk our cows up dry until the end of the third day. We invariably find that a cow which is predisposed to milk fever is almost sure to have it if you milk her up dry during the first or second day. The sudden shock on the nerve centres from taking of the milk from the udder will induce the paralysis which in reality is nothing but milk fever.

We always feed the calves the beestings and we find that there is nothing that will take the place of this in starting the calf right. It is absolutely necesary in order to give the calf the proper start in life.

We find that milking our cows three times a day for the first three or four days does more to get rid of any extra inflammtion and to tide the cow over in case of milk fever or anything of that kind, and to get her system proper adjusted to milking and to stimulate the milk flow. A good heavy producing cow that is capable of milking 50 to 60 pounds of milk per day will actually pay for the third milking. We have some grades of cows of Holstein breed, I will admit, that are milking as high as 73 pounds a day in two milkings. One of these we switched over to three milkings, with exactly the same amount of feeding—more labor, of course, in milking. With the extra milking these cows invariably jump to 85 and 86 pounds of milk per day. I hope there are lots of cows in New Brunswick at present that are capable of producing the 60 pounds and that will demand the extra milking.

The feed of the calf starts from birth and is after all a comparatively simple proces as we follow our practise, and all our experiments in calf feeding have been with this object in view—the producing of the very best possible calf at the least possible cost. Whole milk at present valuations of $2.50 to $3.50 per 100 pounds is the most expensive calf feed that you can handle anl you dairy men must look to some cheap substitute. We have carried on experiments for the last

seven pears in calf rearing. With some we use whole milk with calf rearing for the first four or five weeks as against pail feed. With those that are raised o nskim milk we use some additional flax seed, double milk whey and follow with calf meal either home made or purchased. Our cheapest and our best calves are ou skim milk calves, with whole milk valued at $2.00 per hundred weight, and oats, bran, corn at the prices ruling some two years ago about 50% lower than they are at the present time. At these prices our whole milk calves were costing at five months of age about $16.00 per hundred pounds to raise. At present prices our whole milk calves at six months would cost in the vicinity of $18.00 to $19.00 per hundred pounds. Then our pail fed whole milk calves and calves that were scrubby were costing about 10% more.

With skim milk valued at 30c per hundred weight, we use a good meal substitute such as two parts farm ground midlings, two parts of corn and two parts of cotton flaxseed. The mixture is prepared and fed as calf meal and added to the skim milk, and later on take out and fed as a dry meal, and gradually oats added to that. Calves reared on that basis cost us only $4.00 per 100 pounds of gain. We have reared a number of calves after they were ten days af age on prepared mixtures such as Royal Purple, Blackwell's, Colwell's, Gold Dollar, and several other calf meals. We consider, generally speaking, the Royal Purple one of the best of these methods, Blackwell's and Colwell's very close competitors. Freedom from mustiness is a great feature in any of these prepared calf meals. However, we have reared some fairly good calves starting them at about a week old, cutting the milk out altogether within two weeks and rearing them on this gruel, but they invariably cost us from $7.00 per hundred weight to $8.50 per hundred pounds, while our skim milk calves valued at about 30c per hundred weight, costs us around $5.00 to $5.50 per hundred pounds of gain. It is possible to raise good calves with skim milk, and they are invariably the cheapest all round calf that you can rear. Our practise in calf feeding as the result of our experiments has proved about the following,—We feel that the calf must be started properly so we never give the calf less than two weeks of whole milk. We pail food from the day it is born except in the case of heifers have undue inflammation of the udder. The calf is taken away at birth and starved for twelve hours, and by taking it away at birth the cow never misses the calf and the calf never misses its mother. We feed the average calf from ten to fifteen pounds per day, divided into three feeds, if we have the labor. At the end of two weeks if it is an extra good calf we increase the whole milk and give it one or two weeks of whole milk feed, but with our average calf we start at once to switch over to a skim milk and a meal. We use an equal mixture of ground oats, corn, grain and flaxseed and mix it into a kind of gruel, or we try Royal Purple, Blacwell or Gold oDlar. If rolled oats can be obtained more cheaply per pound than these prepared calf meals, use the rolled oats, with just a little oil cake or flaxseed. This will produce just as good calves with skim milk as you can possibly yet. We feed as high as 20 pounds of skim milk per calf per day if the calf is able to handle it, but we make all changes very gradually. At the end of 14 weeks the calf will take the skim milk and a meal substitute. About that time we start feeding them a few whole oats to help to change the rennet to the adult stage and as soon as the calf is handling whole oats we start crushing the oats and feeding as a separate mixture. We never forget the salt and water for our calves as I am sorry to say that 25% of our farmers are forgetting to do. Salt and water are just as necessary in the feed to be given to calves after they are two weeks old as they are in the feed of milch cows. We keep the skim milk up to six months of age, and at the end of six months we have a calf considerably larger than our whole milk calves—not as fat perhaps, but if they are put on pasture they go ahead and do extremely well, while our whole milk calves invariably shrink for two months.

You men who are rearing pure breds know the ill effect of too much milk for your pure bred show bulls. Invariably they will get a crest which is almost impossible to get off. They will get thick in the throat and as early bulls and later on as two year olds they carry a crest which is decidedly objectionable and which will almost surely go against the animal in the show ring.

The skim milk calf is the thrifty calf right up to two years of age.

Just a point as to feeding of two year old heifers. If there is one time in the history of the dairy cow when you can make the udder induce the maximum capacity of the mammary glands and mammary veins and give capacity for future milk, it is with the two year old heifer. I know in Ontario even in the past dairy season the freshening of two year old cattle is done, but if they calf the calves invariably are too small and are invariably thin. The result is that the two year old heifer is scarcely able to properly feed a decent calf.

The two year old heifers on our Experimental farm, that is—calves at from 28 to 30 months of age, or as late as 33 months with our small heifers—are producing an average of 6000 to 8000 pounds of milk depending on the breed. That is almost twice as much as the average dairy cows produces in Canada, or in fact in any of the eastern provinces of Canada. There is no reason why with proper attention at the correct time, with proper feed and especially just before calving, there is no reason why the two year old heifer should not produce at least 80% as much as she is capable of producing as the mature cow. So from three to four months before calving we start graining our heifers and we feel that if we grain these heifers up to 8 or 9 or 10 pounds of fairly strong meal per day that it is profitable. I know it is contrary to the practise of the average dairy man, but the result we find is this,—we give our heifers feed that invariably produces three times as much milk in the udder, the udder is stretched to twice the capacity of the two year old that is not fed. The softer fat that is on the body of that heifer, as the result of the extra feeding, will be invariably returned within the first three months as extra fat in the milk. That in itself, wtih butter fat at present prices will almost pay for the amount of milk that you have used. I always figure that the production of the heifer, or for that matter of a cow, is about in this proportion,—If you start a toboggan with an elevation of about 40 feet and an angle of 45 degrees, when it strikes the level is will probably run 50 feet. If you start it on an elevation of 100 feet with an angle of 45 degrees, before it strikes the level is will have gained more and more in speed and it will probably run an extra 150 feet. And if you start a dairy cow with a flow of milk and carry her along you will go twice as far and you will produce twice as much milk, and the low producer will follow the same normal decline.

Now just a few words as to rations and I am going to stop. Our rations are all cheap farm grown roughage. Cheap farm grown roughage must be reached and must have the necessary elements or characteristics following,

1. Palatability.
2. Easy Digestibility.
3. Suitability.
4. Succulence.

These in my estimation are the main essentials in growing farm roughage. In valuing feed or in buying feed I find it is well to test it by a little figuring. This is the way I usually purchase all our feed, in the shape of concentration of value when buying good farm grown roughage. Mangles and turnips, for example, contain in total digestible nutriants—that is, starch, fats, carbo hydrates—per ton only 148 tons of digestible nutriant. If you can raise roots at $40.00 per ton (which, with the exception of very abnormal labor conditions, is quite easy in ths Provnce) it means that your gross cost of digestible nutriants per 100 pounds is $2.70. Just in comparison with that, oats at $60.00 a ton—that would be $1.00 a bushel—cost $4.25 per 100 lbs. of digestible nutri ants. In other words, the mangles at $4.00 per ton are almost half or just a little over half as expensive.

In either buying or valuing food stuffs you do it from one of two angles if you actually study those food intelligently. A farmer who has a lot of rich, well cured clover hay has just aout as cheap a source of protein as he can possibly get. Of course clover hay at $15.00 per ton costs you in digestible proteins per 100 pounds, $8.40, as compared for example with any of the grain which you are buying; cotton seed meal for example—almost invariably the cheapest protein,—at $65.00 a ton or $7.00 per 100 pounds just a little cheaper. Barley at $60.00 per ton $30.00 per 100 lbs. of total digestible nutriants,—nearly three times as much digestible protein in your clover hay. Wheat bran at $35.00 per ton costs you in digestible protein $11.37 per 100 lbs.

If a farmer has good clover seed he does not want to buy proteins, particularly for his milch cows. If he owns anything in the shape of meal or grain, what he needs is something that balances about the same. If he has a little more corn than clover hay what he wants in digestible proteins is starch and fats. On that basis he selects his feed for total digestible nutriants. If on the other hand he has a lot of rough hay, middle hay or quite thin hay that is quite woody with a large amount of vetch and consequently rather poor as compared with fine clover, on that basis he wants to buy digestible proteins.

As I see the question of selecting meal for dairy cattle it is a question of either digestible proteins or total digestible nutriants, altogether depending on the grain and quantity of roughage which he has at his disposal. The cheap farm grown feeds, like clover hay, pea and oat ensilage, or oat ensilage, mangles or turnips give the cheapest total digestible nutriants by far, give almost invariably the cheapest digestible proteins, and so in actual practise and as you would actually figure it out, there is no question whatever that the dairy farmer who is basing all his rations on good farm grown roughage is the man who will invariably produce the cheapest milk and make the greatest net profits on his operations.

As to selection of other feed, everything depends on the market. As feeds were some months ago, this is the order in which proteins could be purchased most cheaply,—First, Cotton Seed Meal, second, Linseed oil meal (Linseed oil meal was the cheapest source of protein that was available in quite large quantities. The next cheapest source was wheat bran at $37.50 per ton Montreal freight; that is, either coming from the east or going back west along the branch lines. That would be equivalent to about $43.00 I suppose parallel lots f. o. b. Fredericton or St. John.

Wheat shorts at $5.00 per ton more was the next in order.

Gluten, which is purchased by the starch manufacturers (I presume there is comparatively little of this reaches your market) was the next.

Green leaf screening, which you use in quite large quantities for your hogs, and which is also suitable to replace bran or shorts or oats in the dairy cow rations, was next.

Then oats and barley. However, during the last three months oats have become so considerably cheaper that we find oats and bran vieing for third place. Barley is still far down on the list, it being more expensive per pound of protein.

Corn which is distinctly starchy stood about at the bottom of the list. Dry beet pulp was a little lower than the corn. Now, however, from a view point of total digestible nutriants we find corn pretty well up towards the top of the list on account of the very large amount of cheap starch and cheap fat.

However, wheat bran was on top, wheat shorts next, leaf screening next, then distillers grain for which there is no demand. Cotton seed oil, corn, barley, gluten, wheat and oats, (oats however being considerably cheaper now stand in just below wheat shorts).

It seems to be a comparatively simple process of selecting whatever grains are required for dairy cows if one would just sit down and figure on the total digestible percentage in each of these foods above. You can work out a table in a very few minutes with a very little figuring, and you can with your local market prices tell very accurately just what is the cheapest meal or the cheapest combination of meals in order to balance the roughage which you have on hand.

Some of our best rations for food for our dairy cows during the past few eyars have unfortunately been knocked out by reason of the fact that many of our best feeds are not available at the present time.

The rations which we feed to milch cows weighing about 1000 pounds are about as follows,—

Mixed hay, 15 lbs. per day.

Mangles, if available; if not, turnips, 35 to 40 lbs.

and meal feed at the rate of 1 lb. for every 3½ to 4 lbs. of milk produced, for freshened cows, and considerably less meal for cows as they advance. Another good mixture is bran 4 parts, oats 2 parts, barley or grain 2 parts, oil cake, 2, and cotton seed meal 1 part.

Another good mixture which we use is clover hay 9 lbs., mangles 25 lbs., ensilage of corn or peas and oats 35 lbs., oat seed 4 or 5 lbs.

Another mixture is composed of bran 5 parts, oats 3 parts, barley 2 parts, and oil cake 2 parts.

These are just characteristic rations depending on the amount of succulent food we have and the character and quantity of the dry roughage which we have on hand.

There is one point that I want to mention and that is the question of feeding grain on pasture. With the spring freshened cow going there shortly after freshening on but a soft lush grass, we invariably find that 1½ pounds of cotton seed meal with an equal quantity of bran is one of the very best things to keep her from souring. So the very soft grass of the latter part of May or early June we balance with equal parts of bran or grain oats and cotton seed meal and we feed that 4 or 4½ ponds per cow per day.

After the marked change from winter to grass feed has passed we very often drop the meal altogether after the pasture is good and reasonably firm. However, a little meal, even if it is just ¼ to ½ pound per day is worth a good many hours of work in getting the cows in from the pasture.

However, generally speaking we gather in all the heavy grass for four weeks and when the first pasture begins to get scant we invariably start our summer meal mixture and we feed it to our cows, even on fairly good grass, during July and August. We feed it as high as one pound of meal to five pounds of milk produced and we actually find in some cases it increases the cost of our milk, but generally our milk is so much increased in quantity that the difference will more than pay for the meal given. We use a mixture under these circumstances of oats and bran equal parts and then we add to that equal parts of cotton seed and oil cake, making a mixture of two parts of bran, two parts of oats and about ½ to ¾ each of oil cake and cotton seed. This is a very well bal-

anced mixture for fair practise and is well worth while.

In case of shortage of pasture we in Quebec and Ontario have something which you in New Brunswick do not universally use, and that is the summer silo. The best silo is the silo used for corn which is the cheapest source of supply that you can get as it is already prepared and not as much bother as some, for instance,—peas, oats and vetch cut and bailed to the silo are very much more expensive and more bother. A man would invariably have to leave other necessary work of cultivation or harvesting to haul in that jag to the cows.

Farther West, and I believe a practise which will be adopted here in the East—is one of the summer fallow pasture to take the place of a shortage in your permanent pasture—pasture seeded at the rate of a bushel each of barley, wheat, oats and a little spring rye if you have it. Seed a bushel each of these on three acres (with a little clover seed when it is a little cheaper as seed). It is being used in Western Canada to advantage and we are trying it in Ottawa, and it is really very, very cheap. No preparation is required for food and an acre is able to carry 2 cows 1½ to 3 months if properly handled.

However, the question of pasture as I know is not a pressing one in the majority of districts in this Province as you have a bountiful supply of good pasture for your dairy cows and it is just a question of balancing the grain and the grass with a limited amount of meal, so that there may be no radical change in the feed of the cows, and you may get the feed of the cows that you may get the maximum production at the lowest cost, and that brings me to just this last point:—If we as dairy farmers are not big enough business men to realize that big business—the same as in manufacturing—means our greatest profit and that the small business, even though our margin of profit may be greater, means small profit. If we cannot realize that, then we have something to learn from our American friends. The man who is making his cows produce their maximum under reasonabel commercial conditions will make the greatest net profit on his milk during the year, and will almost nvariably do the best calf raising. The man who is rearing the best two year olds is the man who is producing the best commercial cow, either for the building up of his future trade or for actual sale. The man who is a good feeder is the man who is the liberal feeder and he will make more milk, as I said before, and will make milk more cheaply per hundred pounds month after month than the man who is a meagre feeder and who expects the cow under all conditions to obtain a maintenance ration and sufficient to produce milk either on poor pasture or on poor roughage. The food feeder is the successful dairy man of the present and he is bound to be the most successful dairy man during the next few years.

I believe that the outlook for dairying was never so promising as it is at the present time. Our markets for high quality cheese, butter and for dairy products were never so unlimited as at present. We have excellent home markets. We have any export market which we care to deal with, and it simply means that the dairy men of all Canada, particularly of Eastern Canada must through bigger business and above all through co-operative marketing and increasing the excellence of the manufactured product, continue to top the world's markets with a quantity of high quality stuff.

You farmers of the Province of New Brunswick who have comparatively small quantities of export dairy products at the present time have, I believe, one of the very best fields for export to the United States in the great markets of Massachusetts and farther West and South, and you can, I believe, comand these markets, and especially the building up of export market to England if you will only get after the dairy cow and by giving feed get the quantity of milk and the quality of milk which the cow is capable of producing, if you will only give her a chance. Nothing is produced from air or laziness. The cow cannot do it, and if you give the average dairy cow a fair chance I will guarantee that you won't have to complain so much about the scrub cow or even about the scrub sire. oGod feed will do more towards establishing your industry in a big way than any other successful feature that I could mention.

I really owe you an apology for this rather lengthy, disjointed and probably none too lucid talk of mine. I really have this subject at heart. We on our Experimental Farm at Ottawa have at present about five hundred dairy cows milking and we use our records of feed, lengths of time of feeding, milk production, quantity of milk—that is as to fats and solids as to the different products or the grades of different products—we use this information to the best of our ability to show deductions, so that it may be worth turning over to you and I feel very keenly on this question of better feeding, bigger feeding of this big, capacious, roomy, big-producing cow that we could have all over Canada.

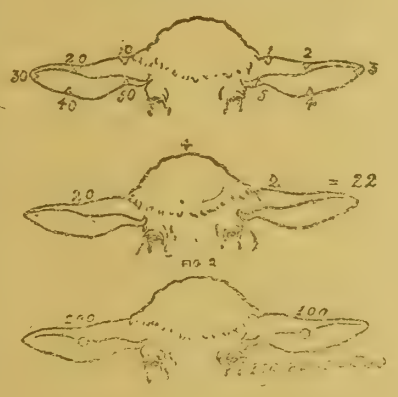
Keeping Records of All Class of Farm Stock by Means of Marking System

The adoption of a system of marking farm live stock is advisable rfom several standpoints. Frequently doubts will arise as to the lawful ownership of certain stock. In such cases only those animals which have been given a distinctive mark can be positively identified and their ownership established beyond dispute. Aside from this aspect of live stock farming, a system of marking affords a means of keeping a record of the age, relationship, performance and financial returns of breeding animals. Breeders of pure-bred stock must pay particular attention to the keeping of such records if they would obtain the greatest measure of success from their business; and it is only by giving each animal in a herd a distinctive mark that reliable records can be kept.

The branding of cattle is perhaps the most familiar system of identification as a meeans of making ownership indisputable. Sheep and swine are generall marked by means of ear-labels or by notching the ears. Sheep are sometimes makred with black paint, a piece of sheet iron on which the owner's initials and a number are inscribed being used to impress the brand on the wool on one side of each animal where it will remain very distinctly until the sheep is sheared. After shearing, of course, the marking has tao be done over again.

When sheep are given ear markings labels are more commonly used than are notches in the ears. But in marking swine, a system of notches is generally preferred. Hogs cannot be prevented from rooting in the ground, or from frequenting mud wallows, and since the metal tage upon which numbers and initials are stamped are quite small, when a tag gets dirty the animal has to be caught and the tag cleaned before the number can be read . Hogs are also prone to fight and snap at each other's ears, and thus the tags are torn from the ears. But sheep and swine are totally different in their habits and the tags which hogs so quicklly render useless may be used on sheep with entire satisfaction to the flocks' owner. Since the sheep must be caught at shearing time anyway, the ear tags may be reead or renewed at that time and it is seldom necessary to catch the animal for that purpose alone.

Ear-labels for sheep are made of metal and each contains a number on one side and the breeders' initials on the other. The label is small and neat and does not disfigure sheep in any way nor cause pain at any time. When properly put in the ear by means of a near punch, such as can be bought from various dealers, the label very seldom becomes lost, but remains with the sheep throughout its life. Sometimes, however, the tags wil lbecome caught in the meshes of



a woven fence or on the barbs of a barbed wire fence, and be torn out. This also applies to hogs which are tagged; these animals are always attempting to break out of their enclosure and frequently become entangled in the fences, with the result that many of the tags are soon torn out. In tagging sheep, each tag should be placed on the lower side of an ear, fairly close to the head; there is then very little likelihood of its becoming lost. Labels can be inserted in the ears of old sheep as well as young.

Marking Hogs

Different breeders have different systems of marking hogs by means of a series of notches in the eears that represent numbers. The system described below is now used in many parts of the country. The lower part onyl of the ears is used in numbering the pigs up to 99. The part next to the head is called the base, and the outer part is called the tip. Then, one nick at the base of the lower part of the right ear stands for the number 1 and two nicks for 2. One nick at the tip of the lower part of the right ear represents 3; one at the tip and one at the base, 4; one at the tip and two at the base, 5; and two at the tip, 6. Two nicks at the tip and one at the base in the lower part of the right ear stand for 7, and two at the tip and two at the base for 8, while one nick in the centre of the lower part of the ear stands for 9. Thus units are represented in the lower part of the right ear. Tens are represented in the lower part of the left ear in the same manner as units are represented in the lower part of the right ear. By this means a breeding herd of 99 brood sows can be marked with absolute accuracy.

As these sows farrow their pigs, the pigs are marked the same immediately after farrowing as the sows. If then, at weaning time or some time later, some of these gilts are to be put into the breeding herd, they are given an additional nick, so as to change their number from that of their dam. Special punches for making these nicks can be obtained from dealers. When the pig is small, or immediately after farrowing a punch with a die that has a rather sharp point shoull be used, while for the larger hogs the punch should have a die with a rounded or oval point.

If a larger number of hogs than 100 are to be marked, the upper part of the left ear can be used for hundreds and upeer part of the right ear for thousands. Such a system is very easily memorized, and the numbers can be easily and accurately read as the hog is in view. About the only way that such markings may be destroyed is when the hogs engage in fights and either tear off part of the ear or bite in new nicks, and even in such a case the tear in the ear is not rounded at the inner point as is the nick made by a punch.

Lambs, Pigs and Poultry

It is very essential that pure-bred lambs and pigs be marked when young so that a correct record can be kept of sire, dam and date of birth of the young animals, which is necessary for their registration.

It is often advisable to mark poultry, as well as the larger farm stock. Leg-bands or the toe-marking method may be employed. Leg-bands are made of aluminum, and are very easily adjusted to a fowl's leg. They can be had in different sizes for different breeds and can be procured at almost any poultry-supply house. Numbers which can be recorded in a book are stamped on the bands.

The toe-marking method is very simple. A small punch which punches holes in the webs of the feet is used. This does not disfigure the birds, and causes practically no pain at the time of marking or afterwards. The little round marks will be less likely to grow together if the chicks are toe-marked when about a week old. A system of marking similar to that given for ear-marking hogs may be devised for the chickens. Keep a record in a book of the way the chicks are marked, so that when they are grown up it will be possible to tell by the aid of the book almost anything it is desired to know about each chick.—W. F. P.

A CHEAP FLY SPRAY

Flies cause considerable annoyance to dairy cows during the summer and not only does the irritation caused by the flies tend to lower milk production but the restlessness of the cows is a frequent cause of inefficient milking.

A good fly spray can be made from: 4½ quarts coal tar dip; 4½ quarts fish oil; 3 quarts coil oil; 3 quarts whale oil, and 1½ quarts oil of tar.

Dissolve 3 lbs. laundry soap in water, add the ingredients of the spray and bring the whole up to 30 gallons with lukewarm soft water. This spray wil keep off the flies and prevent the coats of the animals becoming harsh.

The cows should be sprayed twice a day—in the morning after milking and in the afternoon when in the barn for silage or green feed. With a portable cart, made from a half barrel by attaching wheels and a spray pump and nozzle, two men can spray 40 cows in five minutes.

The watering of early plants should be done with a fine spray nozzle, and not dashed on ini such a way that the seeds will be uncovered.

THE MARITIME FARMER

And Co-operative Dairyman
Registered Trade Mark
Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

MAKE FARMHOUSE CHEERFUL

Apart from the esthetic value to be derived from it beautifying the farm dwelling, modernizing its equipment, is good busness. It is an investment that brings profitable returns. The farmer and his family need wholesome relaxation just as much as any persons constantly employed. The home should be the place in which to obtain it.

An attractive dwelling with an inviting approach acts as a magnet on the tired toiler. The sight of flowers and a well-kept lawn is a relief from the drab clods of the plowed field, the brightness of the blossoms a change from the sameness in the color of growing crops. A cheery interior at once dispels care and bright rooms induce rest.

Every dollar judiciously spent for labor-saving devices and for sanitary conveniences is an investment and labor-saving contrivanves a necessity in these days of enlightenment. They save wear and tear of the human machine and prolong life.

TO REDUCE MILK-PRODUCTION COSTS

Following a study of practical means to prevent the cost of milk production from rising to a point where dairying ceases to be profitable, the Dairy Division of the United States Department of Agriculture has found that four important factors have a direct bearing on the problem. By attention to these factors, all of which are within the control of producers, it has been found that the cost of production can be reduced considerably. The factors are raising the average production per cow, reducing the quantity of concentrated feed given low-producing cows, substituting legume roughage for a part of the concentrates, and more careful handling of the manure. The importance of handling manure properly is secondary in importance only to feed from the standpoint of net profits.

SEND OUT NOTHING BUT THE BEST

"Money cannot buy an inferior breeding hog from ——— Farm. What is not good enough for us is not good enough for you."

This statement was taken from a circular that one of our breeders sends out to his customers and prospective purchasers. It comes from a breeding establishment that has a policy, a policy which if followed consistently would build a good profitable business for any breeder.

This man breeds and sells good hogs this year, and he expects to do the same thing next year and the years to follow. Therefore, he wants satisfied customers, who are necessary to make his business permanently profitable.

It is regrettable that a few men have sent inferior animals into outlying districts where purebreds are not so well established. Just why this has been done we can only surmise. It has been thought he would "get away with it" because the buyer was so far away. The seller does not stop to think that a majority of the buyers of this far away territory know good hogs when they see them. Scrub stuff can't be pawned off on these men just because they are located in outlying sections of the country.

The worst thing about this unscrupulously dealing is that the seller is not the only one injured. It injures every honest man who sells purebred hogs by mail order. It may happen that the buyers in outlying sections get in touch first with a man who ships out animals not up to standard. If he places an order and secures a mediocre animal he might take it for granted that this particular breeder is representative of the breeders who sell purebreds in the hog section. But this is not the case.

Swine breeders have found that to build a good trade in pure-breds a man "must do as he wishes to be done by." They now understand that they must sell the kind of hogs that they themselves would buy if they were in the market for something in this particular line.

A business bult upon this principle will grow and prove profitable.

FARMERS' OWN PROBLEMS

It is a very bad policy for farmers to contract the habit of looking toward the Government for a solution of every problem that confronts them in carrying on their industry. The Department of Agriculture is doing a great deal in disseminating truths regarding agriculture, and farmers should ever be ready to use the material which will apply to their conditions, at the same time never forgetting that their welfare lives very largly in how well they can direct their own affairs. For instance in the marketing of farm products, no Department of Agriculture can solve that problem for farmers.

On both sides of the Atlantic this opinion is held in connection with many of the rural problems.

Sir Horace Plunkett, who is the best British authority on agricultural economics, has this to say on the subject: "We think that in working out our own problems what we can do for ourselves is worth ten times what the Government can do or does for us."

Mr. J. D. Miller, vice-president of the Dairymen's League in America, in substance says:—"We must work out our own salvation as to many of our farm problems. I have profound faith in the ability of farm organizations of this country to solve the problem, if, and only if, they learn team work."

These men have given much time and consideration to farm organizations, co-operative effort, and what may be expected of a Government to assist in solving farm problems. There are those who feel that the period through which we are passing is critical, and that it is going to requre great statesmen to think out ways and means for handling agricultural problems. Too many, in looking towards the Government for help, forget that the Government is of the people, and is not something separate and apart from them.

TO DETERMINE FARM PROFITS

There is much more to consider about the operations of the farm than the amount of money received for the products sold. It is not always the sum of sales that determine the profits of the farm. One must consider the outlay for seeds, tools, hired labor, as well as the farmer's own time. When these amounts are deducted from sales, then the man has some idea of what he is making in profits on his labors. It is up to the farmer to buy to good advantage, hire labor that is efficient as well as reasonable in price, and then sell on the best market. It is only when farming is conducted at a profit that the man will retain his love and interest in the profession.

NAME THE FARM

One of the improvements that some farmers might make in their business this year is to name their farms, then have some attractive letterheads printed. These letterheads should contain the name of the farm and its owner and any other fact that it is desired to advertise, such as the kind of live stock, poultry, seed or grains raised. There should not be too much put on as it will not look well, but it is a decided advantage to have one's letters go out in a business-like fashion. The kind of letters and the appearance of the stationery tell much about the writer, often some things that he does not wish to be known.

SAVE MANURE!

There has never been a time when the making, saving, and utilizing of all sorts of farm manure was so essential. All fertilizing material is high in price, and some kinds can not be had in sufficient quantities at all. Farm manure may be used for a number of purposes to a much greater advantage than commercial fertilizers. The total quantity of manure can be greatly increased by keeping livestock sheds and stables well bedded with straw, leaves, and other refuse about the farm.

* * *

A nation composed of avaricious, selfish people is a nation of selfishness and greed. A nation whose citizens are men and women of honor, industry and truth is an honorable nation that will lead in the affairs of the world.

"Righteousness exalteth a nation." The character of a nation is made from the character of the people. The common people may never hold office or directly conduct national affairs, but the manner in which they meet their obligations in every-day life and the men they select as officials determine what the ideals of the country shall be and what principles should be emphasized.

The responsibility for honesty and equal rights is as binding upon individuals as officials. The farmer who is concerned about his farm and his livestock should give some thought to his country and to the men commissioned to serve him and his neighbors in a public capacity. For farmers are a part of the nation and a very important part. As producers and citizens farmers are indispensable.

* * *

Most dairymen realize, notwithstanding all that may be said to the contrary, that cows having water available all the time will yield more milk than where the supply is restricted.

BUILDING UP LIGHT SOILS FOR BIGGER CROPS

Every farmer knows the importance of an abundant supply of organic matter or humus in the soil. He knows that the sandy soils do not contain as much of this material as do the loam soils, and he knows that if the fertility of the sandy soils is to be increased, they must be made more like the loams as to their content of organic matter.

Myriads of Living Things in Soil

The soil teems with tiny forms of life that feed on the plant and animal matter that is added to it. In the light, open soils conditions are so favorable for the different kinds of life that the plant and animal matter is completely destroyed, while in the heavier soils conditions are not so favorable and a residue of partly decomposed organic mater or humus remains to serve as a sort of food for the crop.

Organic Matter in Light Soils Must Be Increased

It is clear that the farmer cannot buy organic matter and add it to the soil. He must make the land redeem itself by turning under the crop or by returning that portion of it contained in the barnyard amnure to the soil, and by so handling the land that the plant food will not be leached out.

Draw Plant Food from the Air

In an experiment made more than 300 years ago, it was found that a willow tree weighing 164 lbs. had taken only two ounces of mineral matter from the soil, the rest of its food came from water and air. Thus if a crop is plowed under, the soil is improved because the organic matter in the crop was biult of materials that came largely from the air and water.

The greatest amount of organic matter is added to the soil when the entire crop is turned under. Under usual conditions this is not a profitable plan and a modification of it must be used. As for example, the harvesting of the crop, feeding it to stock, and returning the manure to the land This will be a slower way of building up the soil, but it is the more practical way.

Getting Nitrogen from the Air

The grains and grasses must obtain the phosphorus, potassium, sulphur, and nitrogen from the soil. If such a crop is returned to the soil the organic matter therein will be increased but its content in the substances mentioned will not be changed. The only way to increase the amount of phosphorus, potash, or sulphur in the soil is to buy these materials. Nitrogen is one of the elments mose likely to be needed in the light soils, and it is fortunate that nature provided the farmer with a way by which he can draw upon the unlimited store in the air and add it to his soil, and thereby make it much betteer for the growth of grains and grasses. The legumes, clover, alfalft, sweet clover, soy beans, and peas, when grown together with the bacteria that can enter the roots and produce nodules or tubercles thereon, can in some unknown way make use of the nitrogen in the air. Therefore, if a leguminous crop, on the roots of which tubercules are abundant, is plowed under, the organic matter in the soil will be increased, just as when the crop of a grain is turned under, but the nitrogen content of the soil will also be increased, something that could not take place when a grain is grown. It is possible by the plowing under of well inoculated legume crops to build up a soil quite rapidly if no attention is paid to expense. The farmer can, however, by growing well inoculated legumes, harvesting and feeding them, and returning the manure to the land, slowly build up his soil at the minimum of expense.

Must Supply Bacterial Seed

It should be recognized that the legume alone aannot draw nitrogen from the air, but it can do so only when grown in company with the proper bacteria. The bacterial seed must be supplied as well as that of the legume.

In the lighter soils, and especially in those that are acid, it is probable tha tthe bacteria do not live long in the soil in the absence of legume. If a legume has not been grown on the land for two or three years, as might be the case if a rotation of crops is practiced, the bacteria may have disappeared or may have been so reduced in numbers that inoculation is necessary. If the legume in question is not one previously grown, inoculation is essential. Examples of this condition in Wisconsin are found in the introduction of alfale and soy beans.

Proper Kind of Bacteria Must Be Present

The bacterial seed can be obtained by taking soil from a field on which the legume to be sown has been grown very recently. It is not enough to know that the crop on the field from which the soil is to be taken was a successful one, but the farmer must assure himself that plenty of nodules were present, otherwise the soil will not contain enough bacteria so that it can be used successfully for seeding the new field. In a general way, it may be said that each legume requires a special kind of bacteria. The same kind is effective on the common clovers, red, white, alsike and crimson, but is of no value for sweet clover or alfalfa, or are the bacteria which enable the altter to draw nitrogen from the air of any help to peas or beans.

The inoculating material may also consist of a culture of the proper bacteria grown in a laboratory. These organisms can be mixed with water with which the seed may be moistened. An abundance of nodules can usually be secured the first season by this method.

A Schedule for Improving Light Soils

Let us suppose that the main idea in your mind is to get organic matter into the soil as quickly as possible. What is the plan to follow? Sow a profuse-growing legume like soy beans. See that plenty of the proper kind of bacteria are in the soil or are added. Plow under the crop and sow the field to rye. In the spring plow this under and sow again to soy beans. Two years of this treatment will have its effect. This is not a feasible plan under farm conditions, but it is the one which we should approximate as closely as possible.

Keep Fertility on the Farm

To build up a light soil, sell butterfat and milk and hogs rather than beef or grain or hay because it means you will keep more of the potassium phosporusc, and nitrogen you now own on your farm. Grow legumes as much as possible and see that the roots are always thickly studded with nodules. If they are not, inoculate the seed, or if the legume has not been grown on the field for some time, seeding with bacteria may be essential. By growing legumes, properly inoculated, you may be taking dollars' worth of nitrogen from the air and putting it in your soil. This may double or treble your yield, and it is almost certain to increase its feeding value. It offers the best chance of getting something for next to nothing you are likely to meet.

Bare land possesses plant food and washes easily. Keep a crop on your light land constantly and turn under as many of the crops as possible.

Consider the future of your most valuable possession, the soil, as well as the present.—Wisconsin Bankers' Farm Bulletin 69.

MAINTAINING EARTH ROADS

This is a question of interest to farmers in every section of the country, for the mileage of earth roads is still infinitely greater than that af all other roads. An interesting discussion of the methods followeed and the results achieeved where the earth roads predominate, is supplied to the Wisconsin Good Roads Association by Mr. F. M. Sargeant, a division engineed of the Wisconsin Highway Commission. Mr. Sergeant writes as follows:

After a season's experience with the patrol system of maintenance in division No. 7, where we have practically all earth roads, I am more than ever convinced that this type of road can be fairly well maintained by this system, even where subject to considerable heavy motor traffic.

A patrol section should not be more than six or seven miles in length and should be taken care of by one man with team. This man should be held responsible for the condition of his section at all times and should be required to devote all of his time to the work.

The patrolman must have a good team, and the wagon box equipped with a dump bottom. The county should furnish a light two-horse blade grader, road plane, plow, scraper, and necessary small tools, such as shovel, pick, bar, brush scythe, rake, etc.

Use Grader and Planer

In spite of all the claims made for the road drag as a maintenance tool, we find the light blade grader or the road plane far superior to it, and advocate the use of these tools entirely for road maintenance. We find that a road drag having no bearing except on the blade, has a tendency to gouge out the material in soft spots making them still deeper, and giving the road a bad, wavy surface, while the blade grader or the road plane, having a long wheeel base or bearing surface, cuts only on the high spots and distributes the material in low places, building them up, and giving the road a nice, smooth, driving surface. A blade grader should be so constructed that one man can drive the team and make all adjustments necessary while the machine is moving, as only one man is required on this work.

An earth road with low crown and badly sodded shoulders cannot be properly maintained by the patrolman, but should be first trimmed up with a heavier outfit, cutting off and removing heavy sods, properly shaping up the crown, filling low places and opening up drainage.

The blade grader should not be used on earth roads when they are sloppy, but should be used as soon as the material is dry enough to roll nicely on the blade, and pack into the ruts and depressions. And no great amount of material should be moved at one time; a quarter or a half inch cut is sufficient for the best results, furnishing all the material that the blade can distribute evenly. And for a perfectly shaped road neither end of the blade should be allowed to touch the ground heavily enough to leave a cut or furrow in the road bed, the object being to merely shift a small amount of material from the high places to the ruts and depressions.

Use of the Grader

A well maintained road dries more quickly on the center than on the sides, and the first trip with the grader after a rain should always be made on the center, with the blade set to carry the loose mterial out, or into and across the rut and toward the shoulder of the road. A complete round trip should be made in this manner by which time the material out near the shoulder will be dry enough to work nicely nad a round trip or two should be made working the loose material from the shoulder in toward the center. This will leave sufficient material in the center so that the first cut after the next rain may always be made from the center out. Under ordinary weather conditions the material is in fair condition to work with the grader for about three days after a rain, giving ample time for three efull rounds of the section, which should leave even a badly rutted road in fairly good condition. Be sure to always make the first round trip on the center of the road.

The crown of an earth road that is properly maintained may be much flatter than the same type of road that has not had proper care. Six inches of crown on a twenty-four-foot driving surface is sufficient. Care should be taken that the road bed is nicely rounded, and not dragged to a peak in the center or a large ridge of loose earth left there.

Shoulders and Ditches

Shoulders and ditches of a road dry out considerably slower than the the material on the crown is too dry to handle to advantage. By trimming shoulders and ditches at this time the irass and weeds are easily kept down and the ditches kept in perfect condition. Heavy sods and rubbish from the road bed should never be graded off into the ditch and left, but ditches kept in perfect condition. Heavy sods and rubbish from the road bed should never be graded off into the ditch and left, but ditches should always be kept open and clean so that the grader may be crowded to the outside of the ditch at any time, to get fresh material for trimming the road bed.

All stones two inches or larger should be removed from the surface as soon as they appear. A large stone imbeded in the wheel track, aside from being disagreeable to drive over, will soon cause a bad rut in th eopposite track, while a loose, round stone is apt to criple a horse or cause an accident to a fast moving automobile.

Sand and Clay

Very good results have been obtained by hauling and spreading from one to three inches of sandy gravel or coarse sand on slippery, heavy, clay sections, allowing the traffic and use of the grader or planer to mix the clay and sand. The use of a few inches of clay on sand spots also gives very good results, but in this case the clay must be well mixed, into sand, preferably with a disk harrow, and the road bed properly reshaped with grader, bringing a thin layer of sand up over the clay to take the wear, and keep the clay from picking up on the wheels when wet.

Brush and weeds should be kept down on the right of way. Bad turns should be brushed out, so as to give a safe line of vision even if considerable work has to be done off the right of way.

Drain ditches and culverts should be looked after often, to see that they are not filled up. In fact a good, live patrolman can always find something to do to better the condition of his section, and if the work is properly done, an earth road can be really built up into a higher type of road by a good patrol maintenance system.—Hoard's Dairyman.

FIELD CROP COMPETITIONS

The N. S. Field Crops Competition Prize Lists are now on the press. Those who desire copies should write to Mr. F. L. Fuller, Truro, N. S. A new departure included this year is that in addition to the prizes for seed wheat and oats a series of prizes is being offered for seed clover. Production of this commodity should be stimulated by present high prices. There is also a special prize list for competition in turnip growing, for which the Halifax Board of Trade has generously donated the sum of $200.

It should be carefully noted that in order to qualify for entry in the Field Crops Competitions for 1920 in wheat and oats it wil be necessary to use registered seed on the field to be entered. The first steps toward fulfilling this condition should be taken now.

STRAINING MILK

Earnest Kelly and James A. Gamble, Dairy Division U. S. Dept of Agriculture

Milk, as it leaves the udder of a healthy cow, is clean and pure. It contains relatively few bacteria and no appreciable quantity of visible dirt. When cow hairs, praticles of manure, bedidng, or dust are found in milk they are evidence that the product has not been protected properly during milking or subsequent handling. On the other hand, the absence of visible sediment does not prove that the milk is clean, for it may have been carefully straineed after careless production.

The entrance of dirt into milk is objectionable from two standpoints—sanitary and economic. The contamination of milk by manure may add organisms which are injurious to health. Schroeder states: "The real danger from tuberculous cattle lies in the manne in which tubercule bacilli are disseminated with their fences."

He found that tuberculous cows cough up and swallow tubercule bacilli which pass through the digestive system and are excreted in the droppings. If particles of this matter get into the milk they carry with them bacteria which are capabye of producing tuberculosis in human beings or in other animals that consume the milk. Economically also the presence of dirt in milk is a disadvantage. Dirty milk is not so readily marketed as clean milk. Consumers are becoming more critical as to the appearance of the milk they buy. Milk contaminated with dirt contains greater numbers of bacteria, hence it is liable to sour more quickly.

Keep dirt out.

Strain through cotton or filter cloth.

Use only clean, sterile strainer cloths.

Source of Sediment

By far the greater part of dirt in milk comes from the body of the cow. Other sources are the air, the hands and clothing of the milker, and unclean strainers, pails, cans and other utensils. A very great proportion of hairs, manure, straw, hay, etc., which drop into the milk from the body of the cow during milking. Hay, chaff, and dust may also fall or be carried by the wind into milk either during milking or afterward, if it is left exposed. If the milker's hands are dirty or his hat or clothing dusty, some sediment may be carried into the milk from these sources. Unprotected pails, cans, bottles, or other utensils may accumulate dust. When milk comes into contact with them the dirt is washed og.

SUGGESTIONS

1. The milking barn should be clean, and well ighted and ventilated. The stalls should be built with regard to the size of the cows. Droppings should fall in the manure gutter and the cows should have a clean, dry, well bedded place on which to lie.
2. Keep the cows groomed to remove loose hair and/manure.
3. Before milking wash the cow's udders and flanks and wipe with a damp cloth.
4. Milk with clean, dry hands into a clean, sterilized, small-top pail.
5. Remove the milk immediately to the milk house, where it should be strained and cooled at once.
6. Keep milk tightly covered at all times.
7. Protect clean utensils from flies and dust.

What Straining Does

Straining, if properly performed, removes a large part of the visible dirt which may have fallen into the milk. For this reason it is useful commercially in improving the appearance of the milk. It must be borne in mind, however, that straining removes neither the bacteria nor disagreeable flavors that dirt carries int othe milk. nI other words, bacteria can not be strained out of moilk, nor does the process improve the healthfulness of the product to any appreciable degree. The reason for this fact is that bacteria are much smaller then the meshes of the finest strainer. Thus they slip through easily while the larger particles of dirt are caught and removed from the milk. Though the cow hairs and coarses dirt are held by the fire or cheesecloth strainers, many small particles pass through. This can be demonstrated readily by straining a pint of dirty milk through such a strainer into a glass par or pitcher. After standing for a short time much sediment will be found in the bottom of the receptacle.

Taylor determined that 85 per cent. of fresh manure disoslves in milk, 83 per cent, being moisture adn 2 per cent. solid material. He also found that 91 per cent. of the unuissolved manure was visible as sediment at the bottom of the bottle, while 9 per cent. was held in suspension in the milk.

Keeping Dirt Out of the Milk

In view of the facts presented it is evident that the wisest course is, so far as possible, to prevent the introduction of dirt and bacteria into the milk, and to use the most efficient straining method to take out all the sediment that can be removed.

Since the body of the cow is the chief and most dangerous source of milk sediment, preventive measures must begin there. Cows should be groomed frequently to remove loose hairs, bits of manure or bedding. In addition to the flanks, udder and adjacent belly should be cleaneed with a moist cloth just before emilking. If these parts are kept clipped they will be much easier to clean.

Most of the dirt which gets into the pail from the body of the cows falls vertcially during milking. A large part of it and its contamination may be kept out of the-milk by the use of a hooded or small-top milking pail. It can be made from an ordinary milk pail by the addition of the hood, which can be soldered on by any tinsmith at small expense. Many types of small-top pails are on the market, combining satisfactorily the desired points, which are cheapness, ease of use, durability, smallness of opening, and ease of cleaning.

The Dairy Division has examined and scored several thousand milk samples, produced on more than a thousand farms. Ayers, Cook and Clemmer publish photographs which emphasize the relative quanties of sediment found in these samples, classified according to the type of milking pail used, and state further: "The original cost of a small-top pail is little more than that of an open pail; it is no more expensive to care for and is of distinct value in preventing the entrance of manure and dirt into milk; consequently it should always be used."

Dust in the stable air is liable to get into the milk. For this reason every precaution should be taken to have the air pure during milking. Handling dry feeds, especially hay, should not be done just before or during milking. Sweeping the stable during these periods is equally objectionable. If the stable is built with tight ceilings and smooth walls, it will be easy to clean, and dust will not readily colleect in sufficieent quantities to contaminate the air heavily.

The milker's hands should be washed thoroughly and kept clean during milking. If they are allowed to become dirty they are liable to be a source of dirt in the milk, especially if "wet-hand" milking is practiced. The clothing of the milker should be free from dust which may fall into the milk pail.

Care is necessary to protect the milk from dust and dirt after it is drawn. Except when the milk is actually being poured into the strainer, it should be kept covered at all times to prevent the entrance of dust and insects. Much fine sediment is often blown on to the strainer if the latter is left uncovered during the intervals between straining.

Milk should be kept in tightly covered receptacles at all times. Many farmers remove the covers from the cans during cooling to allow the "animal heat" to pass off. This practice is unnecessary and gives opportunity for considerable contamination.

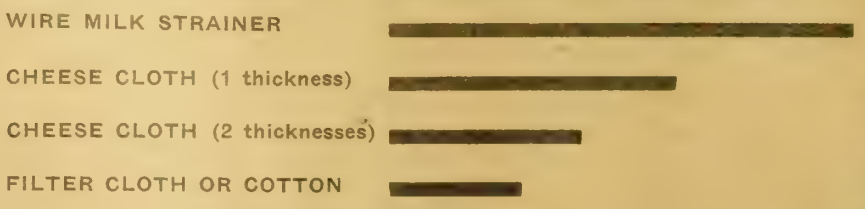
Pails and cans after they are washed and sterilized should be inverted fo drain and dry in a clean place, preferably the inside of the milk house. Strainer cloths may be hung in a similar place. If the se utensils are placed where dust can be blown into them they will colelct dirt which will subsequently appear as sediment in the milk.

Milk Strainers

Even in dairies where great care is used, a certain quantity of dirt gets into the milk, while on many dairy farms, where milk productio is not so highly specialized and other farm activities require the bulk of the available labor, less time is given to cleaning the cows and caring for the milk. Under these conditions it is not surprising to find considerable sediment in many samples of market milk. For this reason it is desirable to strain carefully al lmilk to remove, so far as possible, the sediment which it may contain.

Efficiency of Various Kinds

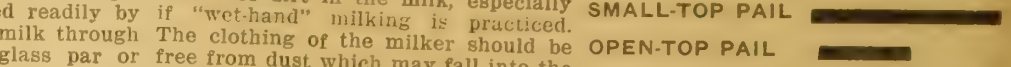
Milk strainers are made of various materials the most common being wire gauze, cheesecloth, cotton cloth, canton flannel, filter cloth, and absorbent cotton. Reports recently received show the kinds of strainers used on about 40,000 farms in all parts of the United States. The following table, arranged in the order of efficiency of material from poorest to best, summarizes the information given:



Quantity of sediment in milk after straining through various materials.

	Per cent. of farms
Wire	35
One thicknes of cheescloth	16
Cotton cloth or more than one thickness of cheescloth	27
Filter cloth	1
Absorbent cotton	21
	100

Keeping in mind the figures shown above, let us consider whether the present systems of straining generally used are as efficient as they should be. The following figure give sa graphic representation of the quantities of sediment in milk after straining through various materials. This illustration is the compilation of figures obtained in scoring several thousand milk samples in competitive contests, where information concerning methods used in production was available. It will be noticed that the milk strained through absorbent cotton or filler cloth contained the smallest quantity of sediment, while wire strainers were least effective in removing dirtt.



Relative quantities of sediment in milk drawn into open-top pails.

To demonstrate further relative efficiency of various straining materials, a series of tests was made in which a measured quantity of manure was placed in each of several bottles of milk. The milk was then strained, a different type of strainer being used for each bottle, after which it was allowed to stand for some time before the bottoms of the bottles were photographed to show the sediment that pased through the strainers. A wire strainer removed hairs, straws, and some of the coarser particles of manure, but did not take out a very appreciable part of the fine sediment. That a single thickness of cheesecloth permits a large quantity of sediment to remain in the milk was shown. Cheesecloth folded so that the milk has to pass through several thicknesses did not remove all the sediment.

Filter cloth was used in one trial. This filter cloth is made of cotton in much the same manner as a carpet; that is, it is smooth on one side while the other side has a "fuzzy" appearance due to the cotton fibres. This fuzzy side is exposed in the strainer so that the milk is poured directly on to it. From the illustration it is evident that this special cloth is quite effective in removing all but a small percentage of the sediment. But most effective of all is absorbent cotton placed between two thicknesses of cheesecolth. This method removes practicaly all the sediment. even in very dirty milk.

Filter cloth can be bought from the leading dairy supply houses, and is comparatively inexpensive. At each milking new squarese may be used or, if properly washed and sterilized, they may be used again until the long fibres become worn. One roll of filter cloth, if porperly used, should last from 3 to 6 months in taking care of the milk from a herd of 20 cows.

Absorbent cotton ca nbe purchased at any drug store. Before using it should be split into one-third or one-fourth of its original thickness, and fresh cotton must be used each time. A 1-pound package should last about a month for a herd of 20 cows.

Cleanliness Essential

Ayers, Cook and Clemmer determined that the greatest original source of bacteria during milk production was unsterilizeed utensils. In a series of 50 experiments they found that when the utensils were sterilized the average bacterial count was 31.040 per cubic centimeter, but that with unsterilized utensils the count averaged 666,-

520 per cubic centimeter. The strainer cloths must receive particular attention, for if they are not carefully washed and sterilized they will harbor millions of bacteria that will contaminate milk at subsequent milkings. It is not uncommon to find straining cloth yellow with old milk and having a strong, cheesy odor. Milk strained through such cloths can have neither a low bacterial count nor an appetizing flavor.

Strainer cloths containing 35,000,000 bacteria per square inch have been found in use on dairy farms. The are of the strainer cloth which is in contact with the milk may be 36 square inches or more e,which means that the milk passing through is liable to be inoculated with more than 1,000-000 bacteria. Furthermore, if the cloth is folded the chances for innoculation are increased in proportion to the number of thicknesses used.

Strainers and strainer cloths, as soon as used, should be thoroughly washed with warm water and washing powder. They should then be rinsed in clean water and sterilized by boiling for 5 minutes, or with steam for the same length of time. After sterilization, strainer cloths should be hung up to dry in a clean place where they will be protected from flies and dust. —Farmer's Bulletin 1019.

BACTERIA OF THE MANURE PILE

The action of various species of bacteria in manure is necessary to prepare it for plant assimilation. The changes that take place in manure from its fresh to its well-rooted condition are due almost altogether to the action of bacteria aided to some extent by molds.

When fresh manure is added directly to the soil, the plant food which it contains is not so readily available to growing plants as in the case with well-rotted manures. The bacteria contained in the fresh manure, aided by those present in the soil, have to break down the complex organic compounds of the manure into simpler forms, or as previously described, digest them before the growing crop can use them.

In the case of well-rotted manure, however, most of this digestive process has been completed by the bacteria, and the plant food present is largely in the right condition to be readily used by the growing crop. The rotting or ripening of the manure is mainly the digestive action of the bacteria contained in the manure.

The kinds of bacteria which bring about this action in the manure pile are the same as those which bring about the digestive processes in the soil. But the conditions which prevail in the manure pile are different from those which prevail in the soil, and as a result we are just as liable to have injurious action, resulting in loss, indeed bacterial action in the manure pile has to be controlled if we are to get best results.

Production of Ammonia and Nitrates

There are large numbers of bacteria in manure when it is produced. These numbers rapidly increase and are added to from the stable floor, the air and surroundings generally, and a rapil fermentation of the manure results. Everyone is familiar with the sharp, pungent, ammoniacal odor which is given off from an occupied horse stall if it has not been cleaned out for a day. This odor is due to the free ammonia which is given off from the manure, liquid and solid, throwing the rapid action of th eammonifying bacteria. When the ammonia is gven off into the atmosphere it is lost, and so this action should be prevented as far as possible.

If the fresh manure is thrown into a pile and the pile is kept well packed and moist the production of ammonia wil lnot be so rapid as to be readily thrown off into the atmosphere. Most of it, as it is produced, will be seized upon by nutritious bacteria and changed into nitrites and these nitrites will be changed by the nitric bacteria into nitric acid and finally result in nitrates. It is the presence of these nitrates in well-rotted manure giving quicker returns than fresh manure when added to the soil.

Everyone who has had anything to do with horse manure will be familiar with the condition known as fire fianging. This fire fianging means loss, as it destroys the plant food in the manure by a slow burning. The condition of fire fianging is due to rapid oxidation in fresh manure induced primarily by the digesting bacteria. In order for this to occur, there must be abundant oxygen within the fresh manure pile. This condition exists when the fresh manure is lossely packed and strawy. In such manure the bacteria will induce rapid oxidation which causes a rise in temperature. The temperature will continue to rise until eventually the bacteria which have started it are destroyed by the heat and much of the manure rendered worthless. Therefore to prevent fire fianging the manure pile should be kept wel packed and moist for the purpose of excluding excessive quantities of air.

There is not the danger from fire anging in cow manure or pig manure or pig manure that there is in horse manure, as these manures are naturally wet and compact. Mixture of these with horse manure, providing the whole is well packed, will thus reduce loss by firefianging.—Prof. D. H. Jones.

PROPER TIME TO OVERHAUL MACHINERY

The proper time for overhauling farming machines is during their period of inactivity and before the rush of spring work. If put off until needed, delay incident to getting repair parts promptly, press of other work, nd the havy recollection of the past season's difficulties may hinder the efficient prosecution of this work.

At the end of the season's work it is a plan well worth while to make out schedule of nedded repairs and adjustments for a particular machine and file it in a convenient place, so when opportunity arises, the work may be taken up and prosecuted expeditiously. The machine itself represents capital invested. It should be housed properly and not left in a fence corner or other out-of-the-way place for wooden parts to rot and metal parts to rust, which, even for short periods, may cause more deterioration than the season's use.

CONSTRUCTION OF A WOODEN STAVE SILO

(Taken from bulletin prepared by S. G. Carlyle, B.S.A.)

Stave silos with concrete foundation are more common than any other kind. If good material is used and they are well constructed they will last for a number of years.

Pine, hemlock or spruce can be used, provided the timber is sound and free from knots. The staves should be 2x6 inches and if tongued, grooved and bevelled will make a strong, tight structure. They are sometimes built without the lumber being tongued and grooved.

The staves should be of two lengths and the joints should be broken alternately. This will add strength to the silo. For instance, a silo twenty-five feet high could have the lumber in twelve and fifteen feet lengths.

The Foundation

In building a silo a good foundation is necessary. It should be laid one to two feet in depth, depending on the nature of the soil, and should be a foot above the general level of the ground. The footing should be one and a half or two feet wide at the bottom, and may be tapered to eight inches wide at the top. Some farmers prefer the silo to extend four or five feet below the surface of the ground, but this means a mnch more expensive foundation, greater difficulty in securing drainage and greater labor in getting the ensilage from the silo. Care should be taken that the top of the foundation on which the staves are to be placed is a perfect circle. When building the wall, five or six pieces of flat iron should be put n the cement at equal distances and should extend above the wall three or four inches to act as anchors.. In these projecting ends small holes should be drilled, and the irons bolted to the staves. This will prevent the wind from shifting the silo off the foundations.

Setting Up

In setting up the staves it will be found convenient to use lath or ordinary flour barrel staves, tacked both on the inside and the outside, to hold the staves in place until the iron hoops are put on. When the points are reacher where the doors are to be located, one stave should be sawed nearly through in the right place for the top and bottom of each door, cutting with the saw a bevel of about 45 degrees. When the wall is finished the saw may be inserted at these points, and the other staves sawed to secure a door of the desired width. The pieces sawed out of the staves should be used in making the doors. A circular plate made of 2x6 material should be nailed around the inside of the staves, level with the top, to carry the ends of the rafters and roof boards.

Band iron or round iron may be used for hoops, round iron being preferred on account of offering less friction in tightening or adjusting. Hoops of five-eighths inch round iron are recommended, and they should be in two lengths to facilitate tightening. The best way to secure the hoop is by means of patented cast-iron lugs, which can usually be secured through hardware merchants or implement dealers. The hoops should be long enough so that they can be lengthened when the silo is being filled, and should be threaded far enough back so that they can be tightened when the silo is empty.

Care should be taken to have the silo air-tight. Great care is necessary at the doors, and where the staves rest on the foundation wall the angle should be plastered inside with a light coat of cement. The staves should be set as close to the inner edge of the foundation wall as possible, so as not to leave a shoulder, as in the setting process an air space would be made which would cause the ensilage to spoil.

Roof and Floor

A cheap and suitable roof may be constructed by taking boards the desired length and cutting them diagonally, putting the base of the board on the plate and the point at the centre, having a turned post about eight or ten inches in diameter for the points of these boards to be nailed to or to form the hub as it were. An opening should be built in the roof similar to a pediment window for the filling of the silo. In parts of the Province where strong winds are prevalent it may be necessary to have rafters to give strength to the roof. These need not be close together. For a silo 15 feet in diameter, 8 rafters will be sufficient. The pitch should be the same as that of the barn.

A satisfactory floor for the silo in this Province is clay well tramped. Concrete may be used but it increases the cost. It is necessary to provide drainage for the silo. This is sometimes provided for by making a saucer-shaped floor, from the centre of which a tile drain is laid. Surplus moisture may also escape at the foundation where the staves rest on the concrete foundation. If there is a lot of moisture being carried away, the ensilage has probably been put in too green; if there is no moisture, it is too dry.

Location.

The location of the silo is important. It may be built close to the barn with only the feed chute of the silo between, or it may be built at a distance of ten or twelve feet so as to leave space for a feed room between the silo and the cattle barn. The silo should be fastened to the barn by guy wires.

Capacity of Different Sized Silos

The following table gives the capacity in tons of corn ensilage of silos of different dimensons, and also gives the number of cows that may be fed from the contents of each silo for a period of 180 days, and at the rate of forty pounds per day for each animal. From this table it will be easy to estimate the area required for the growing of ensilage crops, by putting the yield per acre at from six to ten tons for corn and four to six tons for green oats. A cubic foot of corn ensilage weighs about forty pounds, and of green oats about thirty-three pounds. To get capacity, silos should be built high rather than of large circumference, as the deeper the silo the greater the pressure. This pressure excludes the air.

Dimensions	Capacity in tons.	Cows it will keep for 180 days 40 lbs. per day
12x24	49	13
12x28	60	15
14x22	61	17
14x24	67	19
14x28	83	22
14x30	93	23
16x24	87	24
16x26	97	26
16x30	119	30

MARITIME DAIRY SCHOOL

At the annual meeting of the Dairymens' Association of Nova Scotia, the Prince Edward Island Dairymen's Association and the New Brunswick Dairymen United sanctioned by the annual meeting of the New Brunswick Farmers and Dairymen's Association, held during the winter months, resolutions were passed favouring the centreing of the educational work in Dairying to a greater extent by the building, equiping and operating of one central up-to-date Dairy School to be jointly owned and controlled by the three Provinces, and a committee was appointed at each convention to confer with the committees from the other Provinces to draft up the necessary steps to have the same organized and carried into effect.

This committee was called together and met in the offices of the New Brnswick Department of Agriculture at Moncton on the 1st day of May. The following were present from New Brunswick:—James Stultz, Steeves Settlement; H. F. Hughes, Petitcodiac; H. W. Coleman, Dairy Superintendent, Sussex and E. P. Bradt, Sec'y. for Agriculture, Fredericton. From Nova Scotia, J. D. McKenzie, Bridgewater; W. A. MacKay, Dairy Superintendent and M. Cumming, Sec'y. for Agriculture, Truro.

Regrets were expressed that the deleagtes from Prince Edward Island, Wesley Keefe, Little River; Rev. Dr. Gauthier, Palmer Road and F. T. Morrow, Dairy Inspector, Charlottetown—or a Representative of the Government, were not present.

The Committee. however, got organized and made the preliminary steps to get the idea of the School consummated. The resolutions and conventions naming the committees favoured the centreing of the School at Truro as it could then be affiliated with the Agricultural College and thus be the greatest benefit.

Mr. Coleman acted as Chairman and Mr. MacKay as Secretary. A plan was presented for the organization and operation of the School calling for a School of sufficient size to give a three months annual course in the different branches of Factory Dairying and a concurrent three months course in Farm Dairying which would treat with the production as well as the manufacturing end of the Dairy Work. The question was fully discussed, especially from the new principles that it would involve that of the oft discussed problem of Maritime Union, and Principal Cumming stated that the question of a Maritime Agricultural College had been a live issue just

(Continued on page 886)

HORTICULTURE.

SPRAYING TO KILL WILD MUSTARD

Wild mustard is a well known pest and a great source of loss and annoyance to the farmers of New Brunswick. There are hundreds of acres of fertile land in this province which are so badly infested that hand-picking is impossible. Where the ordinary culture methods fail in the control of this weed it can be killed any time before the flowering period in grain fields without lasting injury to grains or new seeding of grasses and clover by spraying with a water solution of Bluestone (Copper Sulphate.)

The method is effective where the ground is sown to oats, barley or wheat without harm to the crop, and it is possible to exterminate the pest without missing a season's crop. The increase in the yield of grain which results from the plant food made available by the mustard plants being killed will cover the cost of the chemical.

Spraying to kill weeds was first experimented with twenty years ago. Since then it has been demonstrated that sprays of common salt and iron sulphate can be used to kill weeds in pastures in which live-stock is running without offering any risks. Dandelon, Canada Thstle, Yarrow, Red Sorrel, Poison Ivy, Cockle Burr, Mustard species and many other weeds have been killed by such sprays as solutions of: Common Salt, Iron Sulphate, Copper Sulphate, Sodium arsenite and Calcium Chlorid.

The solutions used as sprays to kill weeds are applied by means of spray nozzles which deposit the solution as a fine mist upon the surface of the leaves of the plant. Special forms of spray machinery carrying a long rod or "boom" 18 feet in length with nozzles placed 18" apart have been developed as weed destroyers. But almost any good spray pump which will give good pressure and direct the spray nozzles to spray the whole area at the rear of the machine instead of in rows only will do satisfactory work.

The grain fields should be sprayed when the mustard plants are in the fourth leaf, or before the plants are in blossom. The bluestone solution is used at the strength of 10 lbs. in 40 gals. water. The spray blackens the tops of the blades of grain but no detrimental effects are apparent after two weeks.

Most of our weeds are broad-leaved. Grasses and grains are narrow leaved. Upon the reactions of these two classes of plants to the chemical sprays we depend for results—for injury to the weeds without harm to the crop. One thorough spray will kill a large share of the weeds and if continued each time the ground is re plowed the mustard can be eradicated.

The Provincial Department of Agriculture will demonstrate the control of wild mustard species growing in grain fields in different counties on infested farms the owners of which have a spray machine to offer for the work. Powdered bluestone and a special spraying boom have been procured for the purpose and the experiments will be conducted by the Soils & Crops Division.

If you are interested in the matter of Weed-control by chemical spraying write the Division.

O. C. HICKS,

SMUT SPORES IN SEED DRILL

What is the use of treating grain for smut and then running it through a drill which may have millions of smut spores lining the box and other inside surfaces?

The drill should first be cleaned out with a small broom or brush. It is then best to plug up the drill tubes, sprinkle the inside thoroughly with formaldehyde solution, close up the box and allow it to stand so that the fumes may come in contact with spores that may be adhering to the inside of the drill. Every precaution should be taken that the drill is entirely free of all the smut spores.

WHAT SOIL BACTERIA NEED

Soil bacteria are friends and not foes of the farmer. They are not only useful, but are absolutely essential, and the more there are of them in the soil and the more actively they are working, the better will be the crop returns. We are then faced with the problem of how to encourage their development and activities. To solve this problem we must know the conditions favorable to their development.

First, the beneficial soil bacteria need oxygen, as many of the changes which they bring about are oxidation processes. There is an unlimited supply of oxygen in the air and if the soil is well drained there will be plenty present in between the soil particles to a depth of two feet for the use of the bacteria. If, however, the soil is caked or waterlogged, the necessarly oxygen is not available for the bacteria, therefore, their development and activity is checked and their elaboration of plant food is prevented. To supply the soil bacteria with their necessary oxygen we must therefore keep the soil wel drained and the surface loosened up and pulverized by cultivation.

The second requirement of the soil bacteria is moisture. This does not mean saturation or free water such as would induce a water-logged condition in the soil. So long as the soil is just moist there will be plenty of moisture for the bacteria. Two-thirds saturation is as much moisture as should be present. This moisture should exist as a thin film of water around the individual soil particles, and it is in this film of water that the bacteria live and do their work. There should, however, be no free water between the soil particles as this would keep out the oxygen. Hence, to have right moisture conditions for the bacteria in the soil it should be well drained to carry off all exces moisture in wet periods and in dry periods it should be shaded or cultivated where practicable so as to keep a soil mulch on the surface to prevent excessive operation.

A third requisite for the soil bacteria is a neutral or slightly alkaline reaction in the soil. That means that there should be no free acid in the soil, in other words, the soil should not be "sour." The beneficial soil bacteria will not develop where acid is present. The work of some of the soil bacteria includes the production of acid and if this acid is allowed to accumulate it interferes with further bacterial activities. This aciid as it is produced must be neutralized and if sufficient lime or potash is present in the soil, the acid is neutralized as fast as it is produced. If the acid in question is nitric acid and it is neutralized by potash we get as a result potassium nitrate, which is one of the most valuable nitrate fertilizers, and readily assimilated by the growing plants. If lime is not present in the soil in sufficient quantities to neutralize the acid, then it should be added.

A fourth requisite of the soil bacteria is organic food substances. These are supplied by the sod, stubble, manures, straw, etc., that are plowed in, and these should be present in fair quantities to feed the bacteria. It is this process of the bacteria feeding that breaks them down or digests them, making them suitable for the growing crop t ouse them. This action of the bacteria in digesting the crude organic material added to the soil results in the production of humus, which it is so essential should be present in cultivated soils. —Prof. D. H. Jones.

It is more important that the ground be well prepared and in good condition than that the crop be planted early.

HOULTON, MAINE, U. S. A.

Grow Strawberries for Profit

Do you know that one Farmer in New Brunswick sold nearly $5000 worth of berries from five Acres? That another Farmer sold over $8000 worth from a little over ten acres? These results are not exceptional, any good farmer can do as well who will give his attention to the most profitable crop that can be grown in the Maritime Provinces. We can supply Plants for the professional Strawberry Grower, for the man who grows an acre or two as a side line to general farming or for the family garden. Good strong well rooted plants are more than half the battle in successful strawberry culture. Start right. Don't take plants from an old bed or from the side of the rows as a gift. All Farmers know that poor seed means a poor crop. Dunlaps, Warfields and Beder Woods, $4.00 a thousand; Sample, Glen Mary and Dr. Burrell, five dollars a thousand.

Spraying Materials for 1919

Dear Sir: —

If your Society decides to secure mtaerials from us, it can do so by becoming a member of this Association for the present year by payment of membership fee of $1.00. This will entitle your Society to order all the materials it may need. We would advise you to send in a club order for the total requirements of your members, so that this total order may be shipped to one man designated by the Society, the members to secure their individual orders from him. This would save considerable in freight charges and secure more prompt delivery. If the Society does not order goods for the Society, we will supply individual members for a purchase fee of twenty-five cents.

Prices f.o.b. Fredericton

Bluestone (in crystals) per cask of 450 to 500 lbs., 11½c; fifty lbs. or more 12c per lb.; less than 50 lbs., 13 cents; less than 25 lbs., 14 cents.

Ground Bluestone (will go into solution in two minutes with good agitation)—100 lbs. or more, 12 cents; twenty-five to fifty pounds, 13 cents; less than 25 lbs. 14 cents.

Dry Powdered Arsenate of Lead.—25 lbs. or more, 45 cents per lb.; less than 25 lbs., 46 cents.

Arsenate of Lime.—200 lbs., 24 cents; 50 to 100 lbs. 25c.; 25 to 50 lbs. 26 cents; less than 25 lbs., 28 cents.

Soluble Sulphur.—To take the place of liquid lime sulphur, 11 to 13 cents per lb., according to quantity.

NOTE.—Lilquid lime sulphur in full 40 gallon barrels would be delivered at Fredericton for about $12.00 per barrel or about 30 cents per gallon; therefore as a dormant spray using 1 gallon to 8 of water would cost over $1.50 for 40 galolns of dormant spray, or a little more than soluble sulphur at 12½ lbs. to 40 gallons of water at 11 cents per lb. Forty gallons liquid lime sulphur summer strength costs about 25 cents for 4/5 gallon lime sulphur—as compared to 12 cents for 1 lb. of soluble sulphur to 40 gallons of water.

In estimating the quantities of materials needed we figure on from 1½ to 2 galons of spray solution for each application for one well-grown 15 year old tree; and for potatoes, 80 gallons for each aplication to one acre. If you are not sure of the amount of materials needed we will be able to judge for you if you will state about how many trees you have, what age they are and their distance apart; also acreage of potatoes to be palnted.

We shall be glad to send copies of the enclosed spray calendars to any of your members on receipt of their names and addresses.

Terms of payment are cash on delivery of the goods. Order early and thus be sure of delivery of reliable materials in good time and at a considerable saving compared to ordinary sources of supply.

Yours very truly,
A. G. TURNEY,
Secretary-Treasurer.

TO GET A GOOD CROP OF RHUBARB

Rhubarb requires a loose, rich soil to do best. While the average garden is made up of soil answering this description, it is often the custom to put the rhubarb in some odd corner where it will be out of the way and where it it allowed to shift for itself.

That ,no doubt, is one of the reasons why many people do not have better success in the rhubarb patch. If the ground becomes hard and is not cultivated deep the rhubarb, unless it has already gotten firmly established, will not amount to much.

One year when we plowed the garden we had a fair exambple of what cultivation, and deep cultivation at that ,means to rhubarb. For two or three years we had hardly gotten season. The stalks grew waist high enough stalks off our five clumps to before the end of the summer and supmake half a dozen pies through the plied ourselves and neighbors with all season. We had used the hoe, as that we could use.

Tuition Rates, mailed to any address.

S. Kerr, Principal.

Advertise in the Farmer

application of garden soil, so you can see that it is practically impossible to provide too much fertilizer.

It is best, however, not to be too liberal with it as it induces a rank growth and unless the stalks can be used when young and tender, there is no cause for unnecessarily forcing the roots. It may have a disastrous effect upon their vitality and when not necessary it should not be practiced.

The same amount of fertilizer each year as is used on the rest of the garden wil lbe sufficient for all ordinary needs, but do not cut down on the cultivation. There cannot be too much of that and it must be deep.

SPRAYING POTATOES, 1919

(By G. E. Sanders, Dominion Entomo-Horticulturist, Fredericton, N. B.)

logical Laboratory, Annapolis Royal, N. S., and A. G. Turney, Provincial

Bordeaux made according to the 4-4-40 formula is, of course, the standard fungicide for the potato. Many modifications of this formula are used some calling for more lime and others for more Bluestone. Before using Bordeaux on foilage, particularly where an excess of bluestone is used, one should always test the mixture. The most convenient safe test is with litmus paper which can be obtained from any druggist for a trifling cost. Add lime until this mixture turns the paper blue; it is then safe.

The time to begin spraying varies to a certain extent with locality and season. In general one should apply the first spray in ..ew Brunswick when plants are from 6 to 8 inches high, repeating the application every two weeks for five or six applications.

In spraying Bordeaux on potato plants one should spray so as to wet the under as well as the upper sides of the leaves, covering every portion of the plant surface.

Poisons to Use with Bordeaux

By combining the poison with Bordeaux a less costly type of poison can be used with safety and the grower can control the fungus diseases as well as kill the insects with the same application. Practically all poisons can be used with Bordeaux with a high degree of safety. One should always remember that a small or young "potato bug" is more easily killed than a large one. Therefore, either spray while the "bug" is small or use a larger quantity of arsenic.

In general potato spraying about six tenths of one pound of arsenic oxide is used. To get this quantity of poison approximately the following quantities of the various poisons are required to 40 gallons of Bordeaux.

	Amt. required in pounds	Cost according to 1919 prices
Dry arsenate of lead (standard(	2	.80- .90
Paris Green	1.2	.70- .80
Arsenate of lime	1.5	.36- .40
Arsentae of zinc	1.25	.50-
Arsenate of soda (Arsenoid)	1.2	.36- .40
Paste arsenate of lead (standard)	4	$ .80-$1.00

NOTE.—Costs vary according to the quantity in which the materials are bought.

On account of the element sodium in arsenate of soda, (arsenoid) the arsenic present is more efficient when used with Bordeaux than most other poisons. Arsenic in the form of arsenate of lead is least attractive, although it is the most adhesive of all common poisons. Arsenate of soda should not be used except with Bordeaux.

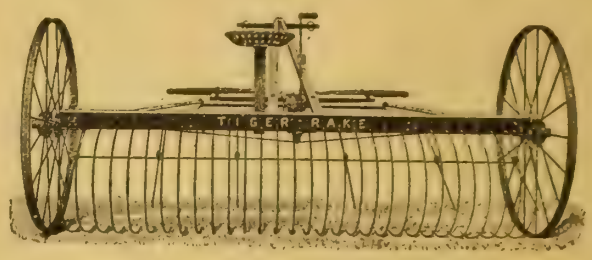
It can be seen from the above that arsenate of lime and arsenate of soda are the cheapest poisons for the New Brunswick potato grower during the season of 1919. Arsenate of lime when used at the rate of 1½ lbs. to 40 galoins of Bordeaux or water is perfectly safe and a satisfactory poison.

Frost & Wood Mower

It's a sure crop-getter because it has 80 years' Canadian experience behind it

The Frost & Wood Mower harvests any Hay Crop—tangled or straight, light or heavy. Doesn't need a nice standing crop to show up well, like other Mowers. It is simple and easily managed, yet it's a marvel of efficiency. Very light in draft because of the high-grade steel roller bearings and other highest grade materials we use.

The knives will work even when cutter bar is raised to clear obstructions, saving time and crop. Our "internal drive gear" alone is enough to sell you this famous Mower. High Carbon Steel Cutter Bar can be set at any angle. Anyone who can drive can "run" it.



THE FROST & WOOD RAKE

Built on a strong, heavy, angle-steeel frame. Parts are riveted, not bolted, so they cannot shake off. Teeth are special high grade spring steel, every one hardened and tested. Years of good, solid, repair-free service go with this popular Frost & Wood rake.

Free folder on Frost & Wood Hay Making Machinery gladly sent, or get a copy from our nearest dealer.

FARMERS

MAKE your banker your financial adviser. Let him help you to shape your affairs so that he will be warranted in giving you ample credit to operate your farm efficiently. Our aim is to assist you in every way possible.

THE CANADIAN BANK OF COMMERCE

2A

Growers are strongly urged to apply the poisons with Bordeaux as at the time when the poison is reuiqred the plants sohuld also receive a protective covering of fungicide for control of the blight or rust. By combining the two sprays, the conrtol of the potato beetle and protection against blight or rust is secured with the same expenditure of labor as if the poison was aplied alone with water.

Warning

REMEMBER.—Arsenite of lime is a different substance from arsenate of lime—and not as safe.

BROOD DISEASES AMONG THE BEES

There are three brood diseases that are of importance to the beekeeper, and two of them are responsible for very heavy losses every year.

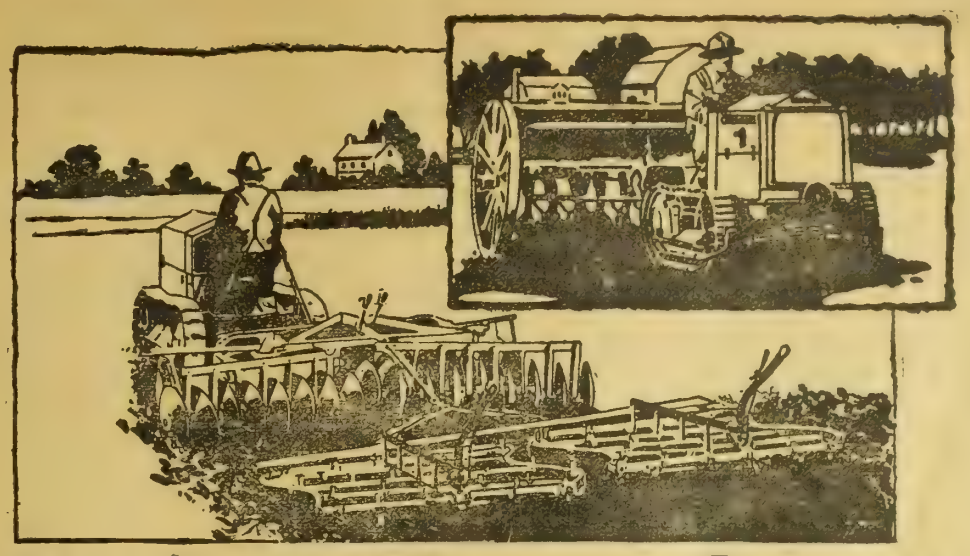
Sacbrood is an infectious disease but transient in character. It may be serious enough at times to weaken a colony considerably, but seldom destroys it completely. It appears in the apiary mostly during the spring and early part of the summer, but cases may be found at any time during the spring and early part of the summer, but cases may be found at any time during the season. The symptoms are irregular brood and punctured cappings; the affected larvae are usually dark gray to almost black in color, and are found lying stretched out on the lower wall of the cell with the head turned up pointing to the upper wall of the cell at the entrance. The body wall of the diseased larvae becomes toughened while the contents of the body are somewhat watery and granular; the whole can be lifted from the cell intact. There is no definite treatment for this disease, but the beekeeper who keeps his colonies at the maximum strength and uses only young vigorous queens need not fear it.

European Foul-Brood

European foul-brood is a highly infectious disease and spreads very rapidly through an apiary, causing very losses especially among black bees and hybirds. The larva usually die before being capped over, while still curled in the cell. The color of the affected arvae changes from a glistening white to a light yellowish or greyish tint, later turning darker and the larva settles to the base of the cell in a shapless mass, finally drying to a dark, detachable scale, which is removed by the bees. This disease may appear at any time during the season but is mostly prevalent during the spring and early summer. European-foul-brood is essentially a "weak colony" disease and the beekeeper who uses only young vigorous Italian queens and keeps his colonies strong need not fear it.

Americana Foul-brood

American foul-brood does not spread through an apiary as quickly as does European foul-brood, but it is harder to combat. The larvae usually die after being capped over and the first sign the beekeeper usually has of its presence is a number of dark, sunken cappings among the healthy brood. Sometimes these cappings may be perforated. If the capping is removed, a dark chocolate-colored mass will be found lying on the lower side of the cell. If a wooden toothpick or something similar is inserted into the diseased larvae and given one or two turns and then withdrawn, the mass will be found to "rope out" to one or more inches before breaking, This is the chief characteristic of this disease. The only treatment advocated for American foul-brood is to shake the bees on to starters in a clean hive and three days later to remove the starters and give full sheets of foundation. The old hives should be disinfected, the combs rendered to wax for foundation and the frames destroyed. The honey is safe for human consumption but must not be placed where bees have access to it. This treatment should be given during a honey flow, if not the bees will need daily feeding.



Cletrac Tank Type Tractor Owners
Do Twice the work with half the Help

A Tractor is farm power.

Buy a tractor which will work the most days in the year.

If your tractor is to pay you it should supplant several horses and men on your farm. It should enable one man to do twice as much work. It should enable you to put more land under cultivation because of faster work at the right time.

What you need is a tractor which will disc, harrow, seed, summer fallow, harvest, thresh, cut ensilage, haul loads, run machinery. A real worker.

The Cletrac tank-type tractor offers you this service 100%.

We say 100% because the Cletrac will disc, harrow and seed over plowed ground *without packing the soil*. Rides *on top* of the soil. Won't even crack an egg buried one inch deep.

So it works faster—works better—works on less fuel.

And the fuel is kerosene (coal oil). Scientific design makes the Cletrac operate *efficiently* on kerosene.

Let the Cletrac tank-type Tractor dealer show you how a Cletrac pays for itself. Write us for booklet "Our Owners Say," telling the Cletrac story in the users' words.

The Cleveland Tractor Co. of Canada
Windsor, Ontario Limited

St. Marys, Ont.

Dear Sir,—I have these tractors working in plowing and preparing land for flax and other crops.

They are as much superior to the high-wheeled tractor, which I used before, as a twenty-horse power steam engine is over the old horse power.

We have plowed with three 12-inch bottoms eight inches deep with the ground frozen to a depth of three inches, at the rate of one acre an hour.

We have found it delivered on the belt over thirty horse power and is actually quicker to set and easier to lighten on the belt than any other rig we know of.

I have sold four teams of horses, which we used for this last year for about one quarter the acreage I will be running this Spring with two tractors.

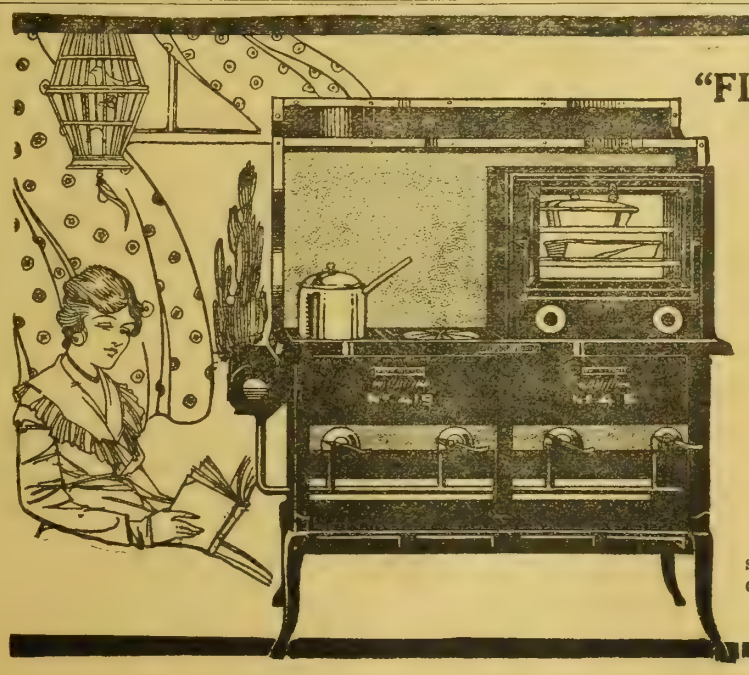
Yours very truly,
(Signed) A. L. McCredie

Cletrac
TANK-TYPE TRACTOR

STORING PUMPKINS

Pumpkins can be kept in storage nearly all winter if a few rules are observed. The garden specialists of Purdue advise selecting well-ripened mature, disease-free pumpkins before they are injured by freezing, being careful to handle them so as not to bruise or injure them, which causes early rotting. Place them in a warm dry room or basement and arrange for good air circulatoin. A few feet around the chimney in the attic or a hanging shelf in the furnace room will answer the purpose. The same direction wil lapply to squashes that are to be stored.

It is not often that a farmer would have good sound apple tree logs of any size, but sometimes it is thought necessary to cut down an old orchard in which there is some good timber. The usual method of disposing of this wood is to burn it, but some income might be secured from it by selling it to some of the saw manufacturers. Apple wood makes good saw handles.



"FLORENCE AUTOMATIC" OIL COOK STOVES

HAVE a cool kitchen this summer—save yourself the labor of attending to a coal or wood fire—use the cheapest of fuels—kerosene.

And don't bother with wicks or slow heating burners.

Let us show you this fine cook stove in actual operation.

Full information about the Florence oil stoves will be sent free to any address upon request to our nearest branch office.

DAIRYING.

SOME PECULIARITIES OF COWS THAT RULE THEIR MILK AND FAT PRODUCTION

[The following article, written by Dr. M. H. Reynolds, gives a lucid description of how the quantity and quality of milk depends upon the hereditary peculiarities of the cow, upon the feed she gets, her ability to digest and assimilate it, and the size of the blood vessels and how they are controlled by the nervous system.]

It may be helpful to a correct understanding of the milk glands to know that they are closely related to skin structures and that the milk producing glands are similar in part to the skin sweat glands, and in part to the skin oil prodocing glands. The milk secreting structure of the cow's udder is to be regarded as a process of evolution from simple surface skin.

It may not be quite pleasant to know that many things are excreted through the udder. Science knows no likes or dislikes, and has no quavers of feeling. Everyone knows that some medicines given to a cow or to a human mother are readily excreted in the milkJin fact, we occasionally give medicines to the nursing calf or baby in this way.

The cow's udder consists of gland tissues proper: i. e., the milk secreting tissues and a connective framework, together with blood vessels, lymph vessels, and nerves. The cow's undder is divided into lateral halves, the partition extending lengthwise of the body. Each lateral half of the udder is encased in a tough, fibrous sack—a sort of capsule, and each side half has two glands; the front and back quarters are not separated by prtitions like the two side halves.

Structure of Udder

The internal structure of each quarter shows that it is divided into distinct masses of gland tissue, and these distinct masses, which we call lobes, are again divided into smaller lobes or lobules. There is one outlet milk duct, or tube, for each lobule. It is through these small milk ducts that the milk from each quarter passes on its way to the milk cistern at the base of the teat.

The mammary glands are undeveloped and rudimentary until maturity and become active, as a rule, in the manufacture of milk towards the close of the first progeny.

From the strong capsule, the fibrous sack, which surrounds each side half of udder, layers of this same tissue branch off and extend into and all through each quarter constituting the coarser framework of that quarter. The relative amount of this connective tissue, i. e., framework tissue, varies greatly in different udders, and varies at different periods of life in the same udder. The farmer who understands this general structure will easily understand why some cows with large udders produce little milk, and other cows with small udders produce much milk. The framework tissue produces no milk. That will be borught out more clearly later.

The Blood Vessels

Most of you are probably familiar with the fact that we have within every animal body two sets of vessels or tubes, through which fluids circulate. We have the blood vessels and the lymph vessels. The blood vessels act as general distrubitors, or wholesalers, of food material as well as wholesale collectors of refuse matters. The lymph vessels serve as retailers and small collectors and are imemdiately concerned in delivery to the manufacturing cells of food materials, i. e., raw materials for manufacturing processes. The lymph vessels also collect the waste—the refuse which is passed on to the blood for excretion.

We have two sets of blood vessels, or tubes, in the cow's udder, as in practically all other structures of the body, i. e., arteries through which flows into the udder pure bood; and we have the veins in which flows back to heart and lungs, the impure blood. There are two sets of lymph vessels; first, the superficial lypmh vessels distributed to the capsule or sheath around the udder and to the skin; and another set of lymph vessels which, all through the udder, supply the little bottle shaped groups of milk producing cells which we will name the alevoli.

The blood vessels split up into finer and finer branches until they are finally microscopic in size. We see these invisible blood vessels, capillaries, the word referring to their hair-like shape. These tiny blood vessels, the capillaries, form networks around the little milk tubes and bottle-shaped groups of milk secreting cells.

The lypmph vessels form tangled meshes or minute lymph vessels, or tubes, in and between the gland lobules and small masses of gland cells. From t hese lymph vessels, smaller, very minute lymph vessels extend to lymph spaces surrounding the little groups of milk cells. These groups of milk cells are arranged in hollow masses not unlike a round water bottle with a long neck. These bottle shaped masses of milk cells will be hereafter referred to as alevoli, meaning small cavities.

The nerve fibres are distributed in part directly to the blood vessels controlling the amount of blood passing

Around and Around and Around !!!
No human hand can keep up a fixed normal speed

If every owner of a fixed feed separator—especially those who *think* they are skimming clean—could see a chart of the great *variation* in speed during one week's separation, they would be amazed. The chart would show that practically all the time the separator was being turned *below* speed and wasting butterfat. Actual tests prove that 95% of all separators are turned below speed most of the time and all separators are turned below speed some of the time. No matter how careful you are, it is humanly *impossible* to turn at a fixed speed, day in and day out. Speedometers, bells and other contraptions only show the wastefulness of fixed feed separators.

SHARPLES SUCTION-FEED CREAM SEPARATOR

SKIMS CLEAN AT ANY SPEED

Before you buy a separator, ask if it will *skim clean at any speed*—as otherwise you are going to lose money. Ask if it is a North American invention, North American owned. Meanwhile write for Sharples catalog and Sharples Book of Old Songs to nearest office, addressing Dept. 79

Butter Parchment at Farmer Office

through the udder, thus controlling the amount of raw material brought to the udder and therefore the quantity of finished product.

Before studying the process of manufacture, let us see what there is in milk to be accounted for in the factory.

Composition of Milk

We may say that milk consists of milk globules, i. e., fat; and milk plasma, that is, water, casein, albumen, milk sugar, and ash. There are certain proteid or nitrogenous bodies in milk. We know these as milk albumen and casein from which we make cheese. The proteid or nitrogenous materials make up about 4 parts in 100. Cow's milk usually has about four and one-half parts per hundred of milk sugar, and from three to four parts per hundred of butterfat, varying greatly according to individuality of the cow. Milk contains also a little ess than one part per hundred of ash or mineral matter; i. e., calcium, soda, potash, etc, and about 87 per cent. water. Colostrum, the first milk drawn after delivery, differs from normal milk in that it contains much nitrogenous matter, especially albumen, which coagulates upon boiling, and little fat, sugar, or mineral matter.

Milk Fat

Milk fat consists of several different kinds of fat combined and put together in little round masses called milk globules. These globules make up a true emulsion with a film of the liquid portion of the milk between globules. It is interesting to note that ash in the bodies of very young animals corresponds very closely with the ash in the mother's milk, but it is very significant to note also that the ash in the mother's milk differs from the ash of the mother's bood, proving manufacturing or at least selective processes in the cow's udder, even for the ash.

Now I am going to try to make plain and simple the process of milk formation.

Process of Manufacture

Where do these come from—this fat and sugar and all this casein and the ash. Well, it is fully demonstrated that they do not exist in the blood. All the blood carries to the udder are the products of digestion, i. e., nutrition materials from digested food, so that back of this manufacturing process in the udder we must have the digestive process in the stomach and intestines.

It would be interesting for any one who is not familiar with this subject and who wishes to follow it farther, to look up the history of the several food groups, the carbohydrates, the proteids, and the fate, from the time they enter the digestive organs until the digestive products are distributed by the blood, and then see what use the body makes of each one of them—especially what use the udder makes of them.

Before pregnancy the milk glands are composed largely of connective tissues; i. e., the framework tissue—and a very considerable amount of fat. The milk secreting cells are arranged in hollow groups called alveoli. Each alevoulus, as previously described, has something of the shape of a long necked water bottle. These are together in clusters with the necks opening into a common outlet tube. The clusters of alveoli are surrounded by masses of fat and framework tissue.

Before pregnancy these little alveoli and their outlet tubes are blocked with masses of cells. As the period of pregnancy develops these cells divide. Some continue attached to the basement membrane which surrounds each alveolus. Others remain free in the cavities of the alveoli, also in their necks and in their outlet tubes. These loose cells undergo a fatty degeneration and pass out in the first milk as colostrum, with which you are all familiar. Colostrum may appear

YOU can't afford to use a second or third grade CREAM SEPARATOR

Get a DE LAVAL

Many users make the mistake of "saving" $10 or $15 in the first cost of a cream separator. More of them continue the use of an inferior or half-worn-out machine simply because it still separates.

These users fail to consider what it means if the separation is not complete; if the capacity of their separator is so small that it needs to be run longer; if it is out of order a good part of the time, or if the quality of the product is not the very best it could be.

They fail to realize what a very little difference means in the use of a cream separator twice a day every day in the year, and what a difference it makes in first cost whether a machine lasts three years or fifteen years.

All these differences led to the great majority of experienced users buying De Laval machines wheu butter was worth 20c. a pound, and they mean just three times as much when it is worth 60c. a pound and when every minute of time saved is worth so much more than it was a few years ago.

De Laval superiority over other cream separators is no uncertain quantity that cannot be seen or measured. On the contrary, it is capable of demonstration to every separator user, and every De Laval agent is anxious for the opportunity to demonstrate it.

If you don't know the local De Laval agent, write to the nearest De Laval office as below and we shall be glad to put him into prompt communication with you.

BLACK LEG CATTLE DISEASE THAT IS CAUSING GREAT LOSS AMONGST FARM LIVE STOCK

It is evident from the many queries regarding cases of animals that have died from blackleg, that the disease is very prevalent in Canada. The following article contains valuable information on causes and prevention of the risease, given by Dr. McGilvary, head of the Veterinary College, Ontario, and at this season the advice proves opportune. The writer says:

Blackleg is an acute, infectious disease of cattle which is manifested in its course by lameness and the presence of hot painful swellings, especially in the region of the hind quarters, the shoulders or the neck.

It is caused by a specific germ, the Bacillus or Blackleg, which, exists in the soil in certain regions, and to some extent appears to be indigenous in cetrain localities, especially where the land is inclined to be scrubby, damp and poorly drained. In some districts the disease is quite common and appears nearly every year, causing considerable losses among young cattle. Cattle are attacked chiefly at from six months to four years of age. Calves being fed on milk and not at pasture are seldom attacked. Cattle over four years of age are less frequently attacked than those under that age. Horses and human beings are virtually immune from Blackleg.

Cause and Transmission of Blackleg

The essential cause of blackleg is a rod shaped germ, termed the Blackleg Basillus, which exists and infects the soil in certain localities. As a result, cattle usually become infected and attacked by disease while at pasture. The germs gain an entrance into the animal's body by infected wounds or abrasions, of the skin, especially in the region of the feet and legs, and in the mucous membrane of the mouth. Infection also results from the consumption of contaminated feed or drinking water. This may take place by allowing the carcasses of cattle dying from Blackleg to remain unburied and thus infect the pasture fields, or the water in ponds and creeks to which cattle have access in feeding and drinking.

Blackleg is not, in the true sense, a contagious disease, as it is not transmitted or spread quickly from animal to animal by contact. The disease is conotracted chiefly from a common source, as infected soils and pastures, which explains the indigenous nature of the disease in certain localities.

It often attacks the young cattle in a herd where they are turned out to pasture in the spring and early summer, and also during the late summer and fall months, after a period of dry weather has caused the small ponds and swampy lands to dry up, thus allowing the cattle to graze over them.

This disease very rarely affects cattle during the winter while they are being kept in the stable.

Symptoms of Blackleg

Once an animal becomes infected with the blackleg germ, the disease develops very quickly, the period of incubation being generally about three days. The course and duration of the disease is also very short and may terminate fatally in from one-half to three days. In cattle, the first symptom manifested is usually sudden lameness ,in which one or other of the legs is dragged stiffly. Soon thereafter a swelling appears in the region of the thighs and quarters, the neck and shoulder or other parts of the body, The swellings in cases of blackleg are very characteristic in that they develop rapidly and are at first very hot and painful, and subsequently become less tender and the skin in the centre of the swelling feels cold and becomes dark colored and dry, like a piece of leather. Another striking peculiarity is that when the swollen parts are pressed or handled, they give a crepitant or crackling sound, due to the presence of gas or air in the affected tissues. The various lymphatic glands are also swollen and may be felt under the skin in different parts of the body, in the form of firm lumps about the size of apples. In addition to the swelling and lameness, symptoms of general disturbances become noticeable, such as high fever, labored breathing and rapid beating of the heart. Sometimes attacks of colic are observed. Finally the animal becomes prostrated and lies on the ground stretched out and soon thereafter dies. While the swellings mentioned are essentially characteristic of blackleg, ther are, however, some cases in which the swellings are either not present or may be too deeply situated in the body to be observed, and the only symptoms noticeable are th egeneral constitutional disturbances.

Post-Mortem Appearances of Blackleg

When any cattle are found to have died suddenly at pasture, it is often advisable to examine the carcass to determine the cause. In cases of blackleg the carcass usually appears to be greatly bloated and a reddish frothy liquid is often seen coming from the mouth, nose and anus. A more or less prominent crepitant, or crackling swelling may also be noticed anywhere upon the body, but more especially upon the rump or other parts of the hind quarters. If the swelilngs are cut into, the tissue appears a dirty brown or dark red color, and when squeezed a dirty, red colored, frothy liquid containing gas bubbles is pressed out, which has a ver yoffensive, sickly odor.

The tissues surrounding the swell- shown an extensive straw colored dropsical appearance. The lymphatic glands near the swellings are much swollen and filled with blood.

When an animal becomes attacked with Blackleg, successful treatment is hardly possible. This is owing to the fact that the disease is so often rapidly fatal and may cause death within a few hours, so that no opportunity is allowed for beneficial treatment. Even in those cases that survive for a period of one or two days, any treatment so far tried has not been found sufficiently successful to warrant much approval. Fortunately, however, cattle can be protected against the disease by means of vaccination with Blackleg Vaccine. Therefore, owners of cattle in districts where the disease is liable to occur should protect their cattle by the use of the vaccine. Two methods of vaccination are in general use; in one the vaccine used is in the form of small silk cords. The method of application in either case is comparatively simple and may be done by any one accustomed to the handling of cattle. In using the vaccine pellet method the vaccine pelet is forced under the skin by means of a sharp pointed injector, which, on being withdrawn, allows the vaccine pellet to remain in the tissues beneath the skin, where it becomes absorbed into the system. In using the vaccine cord method, the vaccine cord is fastened on a suitable sharp pointed needle hook, which is forced under the skin until the vaccine cord is completely concealed. The needle is then withdrawn and leaves the vaccine cord remaining in the tissues beneath the skin to be absorbed into the system.

The most convenient points for introducing either the vaccine pellets or the vaccine cords are behind the shoulder at the root of the tail. In either case, precautions should be taken to have the skin clean, as well also as the instrument used.

As a rule the vaccination protects cattle against disease for a period of six months to one year, but for safety, cattle should be vaccinated at intervals not exceeding that period of time.

In addition to the protection afforded catte by vaccination, it is also advisable, where possible, to keep them

The Most Profitable Method

Catch the Early Markets by Using

WHAT is your time worth? Rounding up your feed materials in the old way takes time; so does figuring of rations and mixing. Feeds on the farm vary in quantity and quality. The ration is liable to be too rich—or skimped. There is loss both ways, either in loss of feed at high prices, or loss of bacon due to imperfect feeding. In short, ordinary feeding methods cannot be accurate and economical.

Monarch Hog Feed

is calculated with accuracy by experts who have handled exactly the same hog feeding problems as you have. They know to a certainty just what Canadian hogs require. The special facilities that we have at our mills and you have not, insure Monarch Feeds always being properly balanced and thoroughly mixed. With these advantages we have produced a feed that will not only finish your hogs quicker and in better condition for market, but it will mean more and better bacon—the good, firm, solid quality that gets the attractive prices for you. It means least cost per pound gain. Guaranteed analysis: protein, 15%; fat, 4%.

Monarch Hog Feed has all the feeding advantages of corn products, shorts and digestive tankage. Owing to the splendid balance in this ration, these feeds are easily digested. Hogs scramble for this highly palatable feed. It gives size, vigor and stamina. It lowers your cost of production, and at the same time gets you the quality prices.

Order a ton from your dealer. You can depend upon deliveries. If your dealer cannot supply you, write us direct, giving dealer's name.

MONARCH DAIRY FEED
has guaranteed analysis of 20% protein and 4½ fat. It is a properly mixed combination of Oil Cake Meal and Cotton-seed Meal with the bulky feeds, bran and corn meal. Though very rich, ensuring splendid results, it can be fed alone.

SAMPSON FEED
This general purposes feed is somewhat similar to Monarch Hog Feed, except that oil cake meal is used instead of digester tankage; it gives results for both cattle and hogs. Guaranteed analysis: 10% protein and 4% fat.

from grazing in such areas as are known to be infected and give rise to the disease.

In all cases where an animal dies from Blackleg, the carcass should be effectively disposed of. The best method of disposal is to cremate or completely burn up the dead body. Where this may not be possible, it should be covered over with some quicklime and buried in the ground to a depth of at least six feet. The dead body should not be dragged over the ground surface, nor should it be skinned or cut open, but should be buried or burned intact in the hide.

Blackleg vaccine is prepared by certain private laboratories and also by the Department of Agricluture at Ottawa. It can be obtained from the department at a nominal cost of five cents per dose, and the instrument required for its application at a cost of 75 cents. A herd, therefore can be protected against losses from Blackleg at a very small cost, and the best course to follow in affected districts is to regularly vaccinate the herd each spring before turning them out to pasture.

Conclusive Proof
can be furnished that the use of good Shorthorn bulls on the farm or on the range increases the size and improves the feeding qualities of the produce of the herd.

COMMON AILMENTS OF SHEEP.—HOW THEY ARE CONTROLLED

It is necessary for sheepmen to understand the common ailments among sheep and treatment for same, for veterinarians as a rule do not diagnose sheep ailments, hence the shepherd should watch carefully for first indication of disease and then treat without delay, while treatment may be effective.

It is the purpose of the writer to mention a few ailments and modes of treatment which have come under my personal observation. At this time of year as we approach weaning time, many ailments should be in good, healthy conditions; not many ewes are too fat. If we expect strong, vigorous lambs, we must keep the ewes strong and heealthy, but often a ewe in good condition is found to have some ailment.

Inversion of the Uterus

One trouble we have occasionally is due to inversion of the uterus, in case of severe labor. The uterus is turned inside out. In such cases I have found the best course is, when no assistance can be had, to raise the ewe's hind quarters by use of ropes tied to the hind feet and throw over something to hold the sheep up. Use warm water with disinfectant, as a wash. If the afterbirth adheres to uterus be careful in removing it. Then very carefully use the hand in replacing the uterus—necessary to be very clean; use disinfectant an hands. A needle with strong white linen thread should then be passed through the skin on each side, and thread tied so as to form a loop, which prevents the uterus from again protruding. Then leave the ewe to rest in quiet.

In case of continued straining causing the skin to tear out, cut heavy srtips form grain-sacks, using same as a bandage, around the ewe, tying in front.

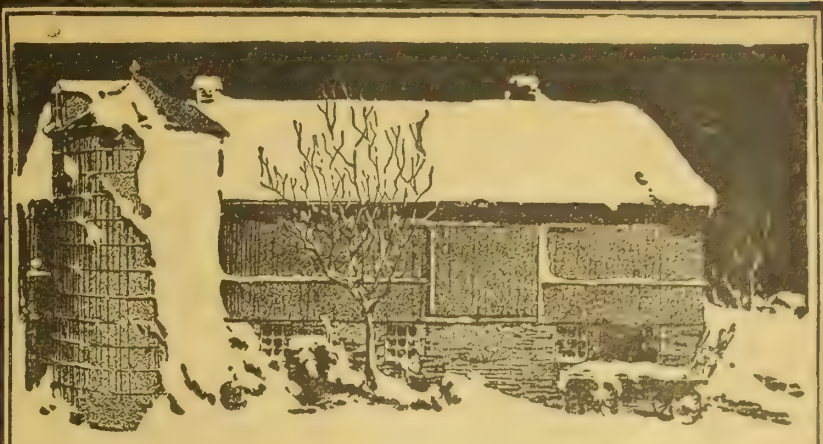
Garget

Garget is a disease consisting of inflammation of the udder. A symptom of garget is stiffness in one hind leg. When garget has occurred the milk must be drained off, the udder massaged, and a purgative given. The dose may consist of four ounces of Epsom salts. I find a hot application —dry heat—used on udder, very beneficial. One can hold a hot brick on the inflamed side, and also keep up the rubbing with one hand. If this does not prove effective, use a bran poultice.

Paralysis in Lambs

Ailments to which young lambs are subject are but few. These disesaes call for special treatment. The most troublesome ailments to which lambs are subject are those of digestive organs, and chief among these is paralysis. This disease is a symptom of chronic indigestion from inaction of stomach, caused by eating more food than can be assimilated. This is a common ailment among heavily fed lambs for early market. The symptoms show that the nervous system of the stomach is affected. The lamb suffers severely as if in great pain. It is unable to rise upon its hind legs, and is convulsed with spasms. One hind quarters appears to be paralyzed —in this case apply a hot iron to warm the muscles. One of the best remedies is hot ginger tea, followed

(Continued on page 892)



June Pastures in Winter Compactly Stored in a Silo

NEXT winter, when pastures are covered with snow, you will appreciate the great saving and convenience of a silo full of rich, juicy silage. It will be like having June pastures in January. Cows produce the same big flow of milk on silage as on pasturage, and you will get it right at the time when dairy products are worth the most. In spite of the great milk-producing value of silage, it is actually 15 to 20 per cent cheaper than any other feed you can use.

Place Your Order Now for an
IDEAL GREEN FEED SILO

Don't go through another winter without silage. Now is the time to get your silo erected so that it will be ready when the crop is ready. Nothing is gained by delay, and if you wait until the last minute you will likely be put to extra expense to get the silo up in time.

Ask for our large illustrated silo catalogue that shows every detail of this silo—how the parts are made and put together, and the quality of the material used.

THE HORSE

"HYGIENE OF THE FOOT," A NEGLECTED DEPARTMENT OF HORSE MANAGEMENT

If farm horses are to have their period of usefulness fully realized, more attention must be given to their feet in the stable. There is no department of horse management which is so much capable of being affected as that relating to the "hygiene of the foot."

Of all parts of the economy of the horse, the foot is universally admitted to be the most important. So long as systems of management continue, only to the routine of feeding and grooming, without rigid attention to the feet, so long will there be a lack of economy in keeping horses as a motive power on the farm. Proper attention to the foot cals for more than ordinary intelligence on the part of those under whose management it is placed.

One of the most competent exponents on the management of horses in Britain, has this to say on the stable management of horses' feet.

"Technical education can effect no higher or human purpose than to let light into the stable in the health interest of our horses. It is surprising how little really useful knowledge of the proper management of horses' feet is possessed by the average groom. We have often heard it said of horses lame in the feet, that they have 'done no work,' as if confinement and idleness afforded immunity disease. It is no part of the stable creed that inactivity and lameness stand in relation of cause to effect. but thi sis too often the case. If we desire to keep the feet sound, they must be brought into daily use, and the nutritive activities stimulated and upheld. The long, continued, forced rest, broken only at intervals, by short periods of exercise, which some horses experience, is absolutely injurious. As the result of this kind of treatment the foundation os frequently laid fo rmany of the worst forms of disease."

Preservation of the Foot

Most farm horses lead a comparatively idle life in the winter time. The instructions given by Colleges and Departments—re the winter care of farm horses—is mostly taken up with feeding, but where horses lead an idle life in confinement—there are certain rules of health aplicable to the feet, as well as to the body as a whole which should be observed. If a poung horse is to be laid idle for the winter, and it is desired to set up his vigor, and encourage his growth on durable lines, and also ensure an increase to his value, he should get his shoes taken off so that sole and frog may be brought in contact with the ground, as nature intended they should. For this, a box stall or yard is indispensible, and the material for the floor of box stall should be sawdust or moss litter to the depth of several inches. If the yard in which he has at his disposal for exercise should be hard with frozen mud, his growing hoof should be protected with light-tips in place of the shoes that have been removed.

The natural tenedncy of standing on hard cement or any hard substance all winter with the work shoes unremoved, is to render the hoof hot and dry, and deprive it of its elasticity and power of accommodating itself to the sensitive part within. This is fruitful of much mischief, and is one of the chief causes of hoof contraction. Naturally weak feet are simply ruined by this practice where a little care would have transformed them to a fit and servicable condition.

Not only from a utility point of view, but for human reasons, it is the duty of the horseman to give opportunity for the natural growth of the hoof. The foot of the horse is a most sensitive part of his anatomy, and inattnetion wil not only set up feet disorders, but the pain it causes affects his general health. If the horseman would take the lesson from a similar condition of neglect to his own feet, where boots that pinch and corns and ingrowing nails are left to torture and torment, sympathy with the horse might end in practical energy towards relief. Anticipate that the conditions that cause disease and pain will arise, as certainly they will through winter neglect, and be prepared to prevent them.

Growth of Hoof

The growth of hoof is influenced by many factors. It is more active in warm weather than in cold, and in well-nourished, healthy animals than in diseased and badly nourished ones. Paralles rings, which are sometimes seen round the surface of the hoof indicate that the animal has been better nourished at times than at other times.

The hoof is composed of a hard, resisting and elastic substance, which remains soft, if moisture is present, but becomes hard and brittle and liable to crack if evaporation has taken place. This condition is often seen in diseased feet, or where the perioplе or glazed surface has been rasped off at shoeing.

To improve the quality of the hoof horn, in the case of weak feet that are lof at the heels, thin in the crust, with horn of loose and coarse texture, cold swabs should be applied to the feet for three or four hours a day, and a little weak contharides liiniment rubbed over the coronet twice a week. When systematically carried out and persisted in, the effect of this treatment on the health and strength of the foot is very marked. Too little importance is attached to the preservative influence of water, in the management of the horses' feet, but unless some arrangement is made, whereby the horse could stand in water for an hour or two each day in the warm barn, the water just covering the hoof, swabing by hand takes toom uch time. For diseased, brittle feet, a hoof ointment is very useful, and wil lsave the time, though scarcely of such lasting benefit as the cold water swabs. Liquid tar, beeswax, honey and glycerine of each an ounce, lanoline and vaseline, three ounces each, make good ointments to encourage the growth of the hoof.

The growth of the hoof is also stimulated by repeated mild blistering. Liquid cantharides should be rubbed into each coronet for about three minutes. In order to obtain good results, it is esential to anoint the part daily after the blister has been applied with a non-iritating oil, such as colza. The blister may be repeated

Prevent Wear and Tear on Axles and Harnesses
Imperial Mica Axle Grease
—coats axle spindles and hub linings with a glass-smooth coat of soft mica and grease that banishes friction between the metal surfaces. Makes loads easier to move up-hill or on level roads. Saves wagon wear and tear. Sold in sizes—1 lb. to barrels.
Imperial Eureka Harness Oil
—keeps leather like new—soft, strong and pliable. Sinks in and keeps water out. Prevents drying and cracking. Makes it last longer. Sold in convenient sizes.
Imperial Eureka Harness Oiler
—makes it easy to keep harness and leather thoroughly oiled. Saves time and work.

after a month. All this has reference to the treatment that should be given to the idle horse. The question of stable management of horses' feet is a very important one, and deserves the close atention of those who have charge of the dumb slaves of the farm.

BAD CONFORMATION IN HORSE'S LIMBS SHOW LIABILITY TO DISEASE AND UNSOUNDNESS

Most of the troubles that afflict the legs and feet of horses are due to either of two causes, viz., breeding with the unsound, and harsh and inconsiderate treatment. This latter cause tells more heavily and more permanently on the horse than on any other species of farm animals. It is quite possible to reduce the ills that are at present rampant amongst horses, by strict elimination of these two main causes of poor management in horse rearinfi. One cannot breed with animals that are predisposed to have leg weakness, and expect their progeny to be free from consequent disease. "What a man sows that shall he reap" is a strue in horse breeding as it is with the field grown crop.

Though breeding gives the right start to eliminate and prevent the spread of unsoundness, it is not everything necessary to fulfill that end. The very best breeding is not proof against results from bad usage or ignorance in care and feeding. The one suplements the other; good breeding must be followed by good care and feeding. Good care and feeding will not free the animal, born of unsound parents, from leg and foot troubles, neither will good breeding prove fully effective in checking the results that come through willful inattention and ignorance. Breeding and feeding are inseparable twins in high class horse breeding.

There are certain characteristics in the formation of the legs of a horse that are indicators of the tendency to leg weakness and foot disease. Every defect in conformation is costly, both to the horse and owner, but not so much because the defeat handicaps the horse in his work, as because every defect predisposes to peculiar injuries and troublesome diseases from which normal conformation is comparatively free.

Conformation of Legs that Tend to Disease

There are certain formations of the legs, easily detected at first sight, that require special attention to enable the animal to overcome, to a certain extent, its liability to leg troubles. Horses that show the defect of feet turned outward are liable to interfering, stumbling and sprained ligaments, and treatment is difficult and perhaps impossible when the cause is due to bad conformation. There are many other causes for interfering, and the most common are defective shoeing, rough road, and working hard when exhausted. . Proper shoeing oftenhelps to prevent interfering. The outside heel, and quarter of the foot of the injured leg should be lowered enough to change the position of the fetlock joint, thereby permitting the other foot to pass by without striking.

Crossfooted or intoed horses are also liable to interfering, and shoeing to prevent it is the only method that will meet with any degree of success.

Lameness in a horse is not often easy to detect, and when detected it is as difficult to explain the cause. In the matter of leg troubles with the horse, acquiring skill in detection is of the utmost importance. So difficult does the diagnosis of some cases become that veterinary skill is many times at fault. .

Spotting the Cause of Lameness

No one who has an interest in horses, or is assigned the duty of caring for them, can afford to neglect cultivating this perceptive quality. It becomes the means of relieving the horse of much pain, facilitating the work on busy days, and increasing the value of horse stock on the farm.

Many of the troubles caught at their commencement can be overcome andset right in the early stages, that would become permanent evils if neglected. All who have the true horse instinct are ever on the lookout for these signs of lameness, as they are shown while the horse is standing or at work. Lameness is not a disease in itself; it is only a sign of disease or injury, and locating the cause becomes a medium of education to the interested horsemen. The usefulness of any of the other animals about the farm is not affected by lameness to the same extent as that of the horse. It interferes with his chief asset, the pulling power of the farm horse.

Viewing the Horse While Standing

When a horse is seen standing with one foot pointing forward a little in advance of its companion the lameness comes from the leg and not the foot. When both feet are in line, but one forearm extended further forward than the other, the lameness is caused by some injury or disease to the elbow. When one fore foot is behind the line of the other, and the whole limb relaxed, the trouble is in the shoulder. With the hind feet when one is held off the ground the soreness comes from the foot. When one hind leg is in front of its fellow, then the lameness is due to some trouble below the hock. If the animal places its hind feet well forward and holds its head high it will be found to be lame in both front feet; and if two front legs are placed well back, with head hanging, then the trouble lies in both hind feet. This is done to take the weight from off the limbs in which the seat of suffering lies.

While the Horse is in Motion

When the horse is in motion, the symptoms are different, the nodding head showing lameness in the fore legs and dipping croup a similar condition in the hind legs. Pain in foot or hock is known by the manner in which the foot is lifted quickly and straight up from the ground, and when the foot is swung in a half circle, it is due to something wrong with the shoulder. Side bone and sprain of back tendons causes the horse to set down his foot, toe first, and when the heel is set down first it indicates founder, ring bone and stifle joint lameness.

When lameness increases with exercise, splints, sidebone and knee joint disease is evident, and when lameness diminishes with exercise, rheumatism and corns are present. Horses suffering from stringhalt, strained back and shivering, show

Horsemen Attention !

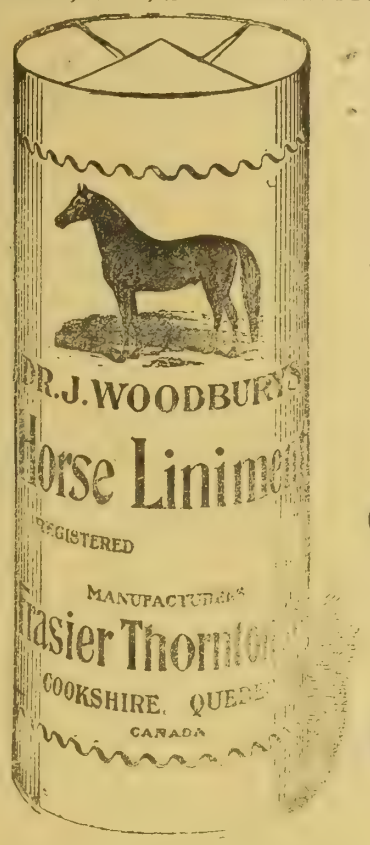
Dr. J. Woodbury's Horse Liniment and Dr. J. Woodbury's Condition Powders will save and preserve the life of your horses. Their use will cure and prevent the disease common to horses, such as Cough, Colds, Distemper, Spavins, Pinkeye, Splints, Curbs, Enlargements, Cracked Hoof, Kidney Trouble, Fevers, Cuts, Sores and will remove bunches of all kinds.

BEFORE USING

Why have a sick or lame horse, when you can get a reliable and warranted remedy? The leading horsement of the Dominion endorse Dr. J. Woodbury's Horse Liniment.

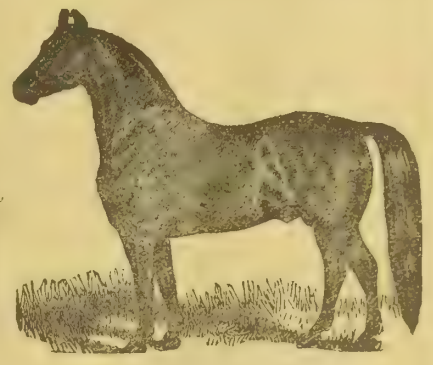
FOR SALE ALL DEALERS

PRICE 35 CENTS



Do you know that "Dr. J. Woodbury's Horse Liniment" is endorsed by all the leading horsemen of the Dominion. Save and preserve the life of your horses by its use. It will cure and prevent disease common among horses.

DEMAND
DR. J. WOODBURY'S
HORSE LINIMENT



AFTER USING

Use this preparation thoroughly for all and every disease of the horse for which it is recommended. Criticise it closely. Carefully watch, mark and notice, its effects, and, honestly judging it on its merits, you will be compelled to endorse it.

Sure Cure for HEAVES

Archie Forbes, of Dublin, writes: "The CAPITAL HEAVES REMEDY I received from you before has done wonders for me. I had a horse last spring which I had given up for a goner. Your Heave Remedy made a new horse of him and I work him every day since."

24 years of success is our reason for selling **CAPITAL HEAVES REMEDY** under our money back guarantee.

ELIMINATING THE DISEASED STOCK

The prevention of poultry diseases is far more important than the cure. It is safer and cheaper and easier to work. The experienced farm poultryman could go into some farm flocks and reduce neext year's mortality rate to a very low point by simply seelcting the most vigorous birds for breeding purposes. The weak birds must be eliminated and none of their eggs used for hatching. By breeding from the strong stock the progeny seem to have a certain immunity to disease. That is why the oldest and most succesful poultrymen never seem to worry about poultry diseases. They have eliminated them by careful selection of the breeding stock and then they use sanitary measures to keep the disease from returning.

The use of mature hens for breeding purposes helps to insure the vigorous chicks which can fight disease. Many flocks are raised from pullets year after year until the stock is weak and susceptible to colds and every disease that comes along. The advice to kill old hens is all right if certain provisions are made for breeding stock. A few of the best mature hens must always be retained to insure a suply of good hatchoing eggs.

Hens which have had colds should not be used as breeders. Hens which are suffering from any disease must be excluded from any yards immediately and either killed or cured. The doctoring of poultry is both expensive and risky, as the hen which is low in vitality from sickness is apt to suffer from other troubles and be a constant danger to the health of the flock. At one time we kept a colony house which we called a hen hospital. If a hen caught cold she was interned. A hen that showed a lack of interest in her feed was also isolated. When these hens seemed alright they were returned to the flock and forgotten and the next year their eggs were incubated along with the others if they were large and of good type. Now we never return a bird without marking her.

Birds that are overfat are not used for breeders, but killed and marketed or used at home. The hen hospital is seldom used now and the flocks are managed without any worry as the birds do not catch cold except in very rare instances. It must be increased vitality in the flock that is making them immune, as they are growing under about the same conditions as when the colds were more plentiful. This simple matter of breeding from the best birds is one of the most important factors in properly breeding poultry.

The value of vigorous breeding stock is apreciated by every farmer as there is nothing more discouraging than illness among the flocks. This point is one of the reasons that we like to rais all our stock on the home farm. Some breeders do not raise many chicks and then plan on buying pullets in the fall to fill their houses. This may be all right in the city or with the farmer with a small flock but the poultryman must raise his pullets in order to insure a healthy vigorous flock which is not easiy susceptible to disease. The home grown birds from vigorous stock always seem to be the best. Of course this does not refer to the custom of buying pens and trios of fine breeders or single birs for the improvement of the home flock but to the scheme of buying a large number of low-priced birds t ofill up the home flocks even though the exact quality of such stock is unknown.—E. L. M.

GOOD NESTS FOR HENS ARE ESSENTIAL

When hens steal their own nests in the hay and the fence corners it will be noted that they are rather shallow, possibly just covered enough to make their eggs roll up toward the centre without piling up on each other. When nests are made in the poultry house they should follow out that principle as far as the litter is concerned. Place just enough straw or hay in the nest to make a hollow just as the hen would make in the hay. Hay can be knotted up and twisted into the nests in such a manner that it is not easily scratched out. Frequently the hens wil lscratch most of the loose straw out of a nest in two or three days.

The egg-eating habit is largely prevented by having the nest dark. The hens should enter the nests on a track built at the rear and the eggs removed by lowering a hinged door at the front. Darkened nests containing sufficient litter will usually prevent egg-eating. Some breeders place the nests beneath the droppings boards but this makes them more difficut to clean and increases the danger of lice and mites obtaining a start. Nests placed along the wall should be at sufficient height so that the farmer ca ngather the eggs without unnecessary stooping. It pays to hinge the bottom of the nests so that they can be dropped down to release uncleaned litter. This should be raked up and removed from the house instead of being mixed with the scratching litter on the floor. Nests with hinged bottoms can be cleaned and sprayed in a short time and filled with fresh litter. There are few cracks and crevices to act as breeding places for mites and lice.

It pays to have plenty of nests for the size of the flock as this will prevent some hens from stealing their nests. The amateur may rejoice when finding a large nest full of eggs, but the practical poultryman knows that those egg sshould have been in the poultry house. He knows that they should have been marketed when fresh and the eggs in the stolen nest must be used at home where every one can bear a rigid inspection before use.

Occasionally hens will lay in the litter beneath the dropping boards. At first thought it might appear best to leave these nests in the litter in anticipation of finding some more eggs there the next day. However, we always destroy such nests by raking them full of litter to discourage the hens laying in places where the eggs are difficult to gather. Eggs laid on the floor may be come lost in the straw or they may be broken by the birds and eaten. This will lead to the egg-eating habit. If an egg is accidently broken on the floor and the hens eat it quickly it does not follow that they are egg eaters as a habit. Many hens will eat a broken egg ravenously when they would never think of picking open an egg with a strong shell.

THE BEST CURE FOR ROUP IN POULTRY

The best cure for cold and roup is prevention. I have not had a case of either in five or six years. Plenty of fresh air, winter and summer, prevents colds. I firmly believe it pays to use the axe when roup appears and

A Tip Top Investment

Foresight is the greatest factor in saving yourself time, money and annoyance.

Don't continue sending good money after bad—by buying poor roofing to patch and repatch your old roofs. Invest in

PAROID A NEPONSET ROOF

and obtain lasting satisfaction, durability and economy.

Once Neponset Paroid Roofing is laid it forms an ideal roof, either on new buildings or over old shingles. It can be put on quickly without litter or fuss. Costs half the price of shingles and pays for itself by wearing for years.

Neponset Paroid Roofing can be used on any building no matter how large or small. Its fire and weather-resisting properties give it first place among roofings.

Neponset Paroid Roofing is made in three colors, red, green and slate grey.

follow this by disinfecting the poultry house. I have it from authority in which I have the fullest confidence that where the poultry house can be shut tightly both colds and roup can be prevented by fumigating with zenoleum, while ethe fowls are on the roost at night. Heat a brick until it is really hot, put it in an old kettle and pour the zenoleum over it, so that it will volatize and fill the room with the fumes. A small quantity is sufficient for the average sified roosting room. eSt it under the perches, so that the fumes fill rise up among the fowls. I have a notion that any coal-tar, sheep or hog dip would be equally effective. Where the cold is slight coal oil squirted from a small oil can into the nostrils and the slit in the roof of the mouth usually cures it. eFeding epsom salts in winter is a good prevention of colds or digestive disorders. Mix into the mash once a week a quarter of a teaspoonful of the salts ofr each full-grown hen.

I am among those who do not believe that gravel is essential to hens, so long as they can get all the oyster shells they will eat; yet I have not quite the courage of my convictions, and I feed a little grit while feeding unlimited oyster shell. Poultry grit prepared for use can usually be bought at any store where oyster shell is kept.

MILLER PURVIS.

ADVENTURES OF A POULTRY JUDGE

(By Miller Purvis in the Breeders' Gazette.)

At a show in a Tenessee city one woman exhibitor followed me right through. She had a pair of Rouen ducks on exhibition, and was as anxious to get a prize as if her life depended on it. She was the wife of a pawnbroker, and of the race that usually keep pawnshops. She was magnificently arrayed in black silk and fairly blazing with gems. Diamonds, rubies, sapphires, pearls, gold chains and silver ornaments decked her hair, hands and person in lavish profusion. If I could have made one grab at her and got away with it I could have bought a farm.

After she got first prize on her ducks she was more faithful in following him and talking about them than before. I was judging bronze turkeys and found what I thought was a defect, but was not certain. I had a morocco covered edition of the "Standar" in my pocket which I took out to consult about the point over which I was in doubt. The begemmed lady and her friend were the only ones near me. I laid my "Standard" down on a coop and turned to the bird I was judging. A half-minute later when I reached for my "Standard" in my pocket which I took of the two women had it, but I had not the nerve to take it away from her and never saw it afterward. I have wondered many times just why that book was so brazenly stolen.

I regret to say that a few exhibitors take occasion to become hilarious during the shows which they attend. At such times some of them have made funny breaks at me. At a show in California one exhibitor was drunk regularly, morning, noon and night. He had a magnificent exhibit of Orpingtons and I gave him about every prize for which he competed. That evening he came around and told me with a very serious manner that he had little use for me as my judgment on the Orpingtons was absolutely wrong. I told him I would gladly reverse my judgment if he asked it, but he wandered away. The next morning he came around just nicely "lit up," but still in full possession of his faculties. He said he had an apology to make for what he had said the day before, as the birds I had given the prizes to belonged to him, a fact of which I had not before been aware.

At a big show in British Columbia a man came weaving down the aisle where I was trying to select the best ten from among thirty-nine White Wyandotte pullets, all of which looked very much alike to me. He watched me a little while and then said: "Shay judge, know what I think of you?" I replied that I did not know, but would be glad to have his opinion. He said: "Some o' them birds ish mine, y' un'erstan', an' I just's leave have you put 'em in a bag an' shake 'em out; judgment'd be jus' 's good." In the circumstances I came very nearly agreeing with him, I told him so and he wandered away happily.

Even though a soiled egg may be perfectly fresh and good, it is very hard work to make the buyer believe it and he is wililng to pay two or three cents more a dozen for clean ones.

BRANDRAM'S Genuine B.B. White Lead is free from gritty particles—it falls from the stirring paddle in a stream of velvety smoothness. It breaks up so easily and mixes so readily with linseed oil that the labor preliminary to a painting job is greatly reduced when this splendid white lead is used.

TEN COMMANDMENTS

1. Keep better poultry: Standard bred poultry improves the quality and increases production.
2. Select healthy vigorous breeders: To produce strong chicks.
3. Hatch early: To produce fall and winter layers.
4. Preserve eggs when cheap for home use.
5. Produce infertile eggs except for hatching.
6. Cull the flocks: To eliminate unprofitable producers.
7. Keep a small back-yard flock: To supply the family table.
8. Grow as much of your poultry feed as possible.
9. Eat more poultry and eggs: To conserve the meat supply.
10. Market the poultry profitably: By fattening on the farm and carefully observing market conditions.

Most hens do not obtain sufficient exercise in winter, but by feeding them clean ration in litter both night and morning they wil lget all the exerecise they need.

An active hen with the proper rations will want to lay right along, and most hens under two years of age will keep active ewithout exposing themselves to snow and cold.

MOCK DUCK

Chop finely 1 lb. of lean raw beef. Season highly with salt, pepper and onion juice, shape around a roll of stuffing (dressing) and bake 30 min. in a moderate oven.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. HANDSOME IS, WHO HANSDOME DOES

(By Gertude Estham Graham, Elmsdale, N. S.)

As Kathryn Bennet walked along the country road her thoughts were scarcely in keeping with the beauty of the spring morning. She was living over agin the scene with her brother, the previous evening, when she announced the breaking of her engagement with Arthur Wilson.

Six months ago when Arthur Wilson had asked her to be his wife, she thought her happines was complete. He was weathy, talented and popular, and to her unwordly mind, he seemed a model of manly vritues.

Kathryn was the daughter of wealthy parents; but delicate health for several years had prevented her from going into society; and although she was twenty-four, she still possessed the charm and unspoiled sweetness of mind of a young girl, and she had small knowledge of life's evils.

Therefore, when rumors of Wilson's affair with the daughter of a country farmer the previous year, reached her, she was horrified. And when, confronting him with the story, he admitted it, but excused himself on the grounds that "he was no worse than the other felolws of his set," and he "had settled several thousand dollars on the girl," her respect and love for him suddenly died, leaving her the dull ache of a heart which has lost its faith.

And then her mother severely condemned her for childishness in making a fuss over such a matter and breaking such a "splendid match."

"Why, Kathryn," she had said, "your idea of a Sir Galahad sort of a man is antiquated. Young men of today must have their fling, but they settle down when they wed. If you expect a saintly man you will look in vain for a husband."

Hardly noticing where she was going Kathryn turned into a road, her mind filled with doubt and despair. Was there no man she could have faith in, one whom she could look up to and respect? An abrupt turn in the path brought in view a forest glade, carpeted with velvety grass and lovely yellow violets. Forgetting her perpexities she sank to her kneees, and began picking the delicate blossoms. Hearing a sound, she rose to her feet and confronted a man. Her first thought was "What an ugly man!" Her nesxt, "what wonderful eyes."

Surely the two presented a strange contrast. She, tall, lovely and graceful, her air bespeaking the aristocrat, He, with twisted misshapen body and homely features and a smile half whimsical, half bitter, redeemed only by fine eyes, and a tender, sensitive mouth.

She was the first to speak and they fell into a conversation, which, beginning with the beauty of the woodland scene, grew until they were talking like old friends. The purity and nobility of his thoughts were a revelation to the girl, and the charm of his manner mad eher forget his deformed body, and when she learned he lived near her father's country estate, she asked him to call. Their acquaintance grew rapidly that summer in spite of her mother's protests.

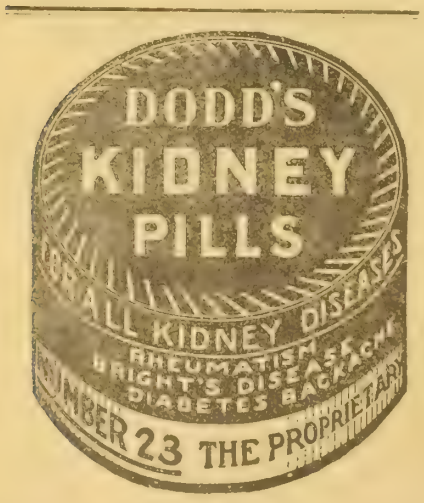
John Leighton was only a poor country doctor, whose life was devoted to his patients, mostly people of the humblier sort. His deformity made him a shy, sensitive man, and if it had not been for his practice, his life would have been a lonely one indeed. As it was his kindness, unfailing sympathy, breadth and charity of mind made him the idol of the village. But his friendship with Kathryn was a new experience in his life, and it brought him many mappy hours until he realized he loved her. The knowledge brought him pleasure and pain, but the bitterness almost drowned the sweetness.

So one evening at the end of his call, as she walked with him to the gate he told her that he must say good-by. The old bitterness crept into his voice, as he said, "I have been a fool in letting myself drift from friendship into love; for it is come to that; I, poor, ugly cripple, have presumed to love you, and so it is best, we shall not meet again."

"Is that all?" asked the girl, calmly, though her heart beat riotously, and her cheeeks flushed; 'are you not to ask my wish? I cannot give up my friend easily."

"Girl," he groaned, "do not make it harder. I cannot see you and not suffer. Friendship is beautiful but love is more, as I cannot have that let me say good-by."

"John," said the girl softly, "listen. You speak of your poor crippled frame but I love it for the great manly soul that dwells in it. Do you know what you are to me? You have taught me faith and trust. The unselfishness of your life, the purity of your manhood, and the depth and earnestness of your soul mean more to me than aught else." Bravely she raised her face to his and said, "John, cannot you read in my eyes that I love you?" As her voice sank to a whisper he thrilled with wonder and joy of it all and gently drew her to him in their first kiss.



WASH DAY MADE EASY

The reason why most women dread wash day is that they have not the proper appliances with which to work. "Oh," they say, "If I only had a few conveniences, or a laundry, I could get along very well."

In almost every case in which this camplaint is heard, there are remedies that can be applied at very little expense, and it is of some of these that I want to tell you in this article.

The things that make washing hard work are: stooping, turning the wringer, lifting heavy pails of water to and from tubs, and carrying baskets full of wet clothing. In the average family all these can be made easier or done away with altogether.

Consider the wash bench, for instance. Generally you will find the same trouble with this as you do with the kitchen sink; it is too low to allow the worker to accomplyish her task without physical discomfort. So the very thing to do in making your laundry work lighter is to raise that bench so that you can rub clothes there without stooping. It may have to be blocked up as much as twelve inches before you can work at it without causing a backache.

A Wash Basket on Wheels

Then get some contrivance to raise your basket to the same height so that there wil be no necessity for stooping over when you have to take any articles from it. The best thing in this line is a little platform of the right height on wheels, provided with a handle like a child's express cart, which can be run about the room in which the washing is being done as well as in the drying-yard. A woman who tries such a cart will wonder how she ever managed to lug a heavy basket about the yard.

Now for the tubs. If you have to buy new ones, get those with faucets fastened into the side. Some of these spigots are suplied with screw-threads and such are to be preferred over the plain ones. You do not need to be discouraged, however, if you cannot afford such tubs. Galvanized or wooden ones can be perofrated and a spigot set in by a tinsmith or a carpenter at very little expense.

Emptying and Filling Tubs

A long piece of garden hose attached to the faucet, when necessary to empty the tub, conducts the water out of doors withou the expenditure of the usual amount of valuable time and energy. This hose can be made to fill the tubs as well as empty them It is a simple matter if you use city water and can screw the hose to the bibb at the sink; and if the spigot there has no screw threads, it can be replaced by one that has. Cistern water can be pumped into a large funnel to the small end of which the hose has been fastened by a wire or cord, and so conddcted to the boiler or tubs at a great saving of time and strength to the worker.

Boilers that Save Labor

The newest boilers are provided with screw hose bibbs so that they. too, can be emptied without the usual labor of lifting heavy pails. One of the very latest receptacles in which to boil clothes has t rotary wheel inside. This is a great convenience in stirring the boiling garments and in removing them to the rinsing water, to say nothing of the assistance it affords in cleansing the clothes. Such a boiler made of copper, if properly cared for, will last a lifetime and will more than pay the buyer for the amount it costs by making the work of wash day less arduous.

The motion required in rubbing the clothes on a washboard is very trying and can be almost entirely avoided by means of a good scrub brush such as is frequently bought for the small boy with which to wash his hands and feet. After a very soiled portion of the garment has been exposed on the

ROYAL YEAST CAKES

Now that the new government standard flour is in general use, the quality of the yeast you use is more important than ever. Use Royal Yeast Cakes. Their quality is absolutely reliable. Bread made with Royal Yeast will keep fresh and moist longer than that made with any other.

E. W. GILLETT CO. LTD.
TORONTO, CANADA
WINNIPEG MONTREAL

KING COLE TEA
"You'll like the Flavor"
The Big Value Package that is Guaranteed.
Perfectly packed in bright lead foil, and price marked on every package.

washboard, it can be rubbed with soap, then scrubbed with the brush over the uneven surface. The result is just the same ts that acocmplished by the more fatiguing movement, and the process is far easier on the clothes—and on the temper of the worker.

Better than al lthese things combined, however, is a good washing machine. If you have water or electric power, the operation of such a convenience is a simple and inexpensove matter; but a hand machine is better than none if you canot have other motive power. A water power machine that will do good work for years can be bought for as litle as fifteen dollars; one designed to be run by electricity may cost three or four times as much. But is far more expensive to be without such a labor-saver than it is to have one.

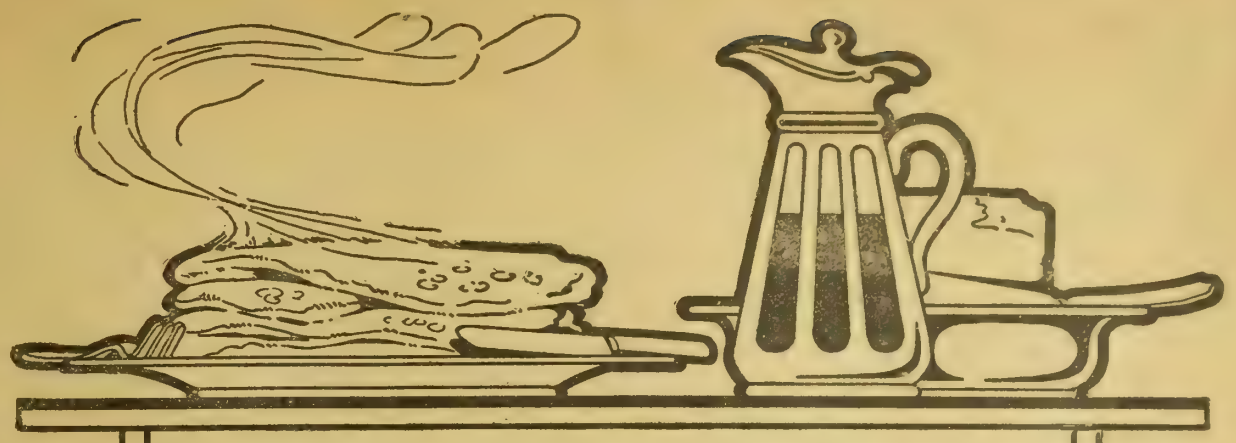
Buy a Good Wringer

It pays to buy a good wringer—and more than one, if you can afford it, because that saves changing from one tub to another. A wringing machine run by water power or electricity should be in every household able to make use of such up-to-date methods. While the initial expense is greater than that of the old-fashioned wringer, such a machine is inexpensive to run and makes it easy for a woman to be sweet-tempered after doing a large washing. There are few housekeepers who would not like an electric drying machine, but just at present the possession of such a convenience is quite out of the question in the average family. On the other hand, there are many who have the means of making a splendid clothes-dryer at almost no expense.

Drying the Clothes

A rack built of wire or slender strips of wood about the hot-water boiler in the kitchen wil prove a boon in cold or stormy weather. A wooden clothes rack built in three or four panels is another great help. Clothes can be hung on this. Then, when you are ready to leave the kitchen, the rack can be adjusted so that it will suround the range on three esides and in a surprisingly sort time the garments will be ready to be sprinkled. On very cold days, too, small and flat pieces can be hung on this rack and the whole contrivance taken out of doors when it is full. This practice saves many a bitter experience of hanging up clothes in a biting, stinging wind.

Still another convenience is a cheesecloth bag in ,which doilies handkerchiefs and other small pieces can be slipped after they have come from the wringer and the whole fastened by a large safety pin to the line out-of-doors.



HOT PANCAKES!

Yes, But-- What are pancakes worth without syrup? It is the syrup that gives the flavour; and there is no other syrup that tastes just as good as

CROWN BRAND CORN SYRUP

For hot pancakes, hot biscuits and muffins, and a dozen other Table and Kitchen uses, housewives with the widest experience use Crown Brand, every time—the golden syrup with the cane flavor.

For Marmalade and other preserves, we recommend our LILY WHITE Corn Syrup.

PENSIONS FOR MOTHERS URGED BY THE INSTITUTE

(St. John Telegraph)

There was a large gathering of representative women at the monthly meeting of the Women's Institute held in the basement of the Congregational Church, St. John, recently with the president, Mrs. J. W. V. Lawlor, occupying the chair. Arrangements were made for holding classes in household subjects and much of the evening was spent in discussing the mothers' pensions scheme; the meeting passing a resolution in favor of such pensions.

Mrs. Richard Hooper made a very strong case for mothers' pensions. She spoke of a particular case of a widow of forty with four children and no money saved, saying that to this widow the following courses were open: first, to put the children in an institution and go to daily work; second, to go to daily work and leave the children at home in danger of fire or to roam the streets and eventually appear in the juvenile courrt or, third, to stay at home, wear herself out physically and mentally trying to make ends meeet, or, fouth, to starve—or finally seek help through legislation. Mrs. Hooper went on to tell how France had first established mothers' pensions in 1908 and Switzerland had followed quickly, as that country discountenanced institutions for its children or the aged. She also spoke of the method now used in Chicago, whereby $7.75 is allowed to a widow for each child and the money is raised by taxation . She strongly urged the necessity of legislation in New Brunswick that would give the children home training rather than institutional, saying that although taxes were heavy, there was joy in helping the right way at the right time and that the only real foundation for good citizenship was laid in early home training.

Mrs. Coates said that Manitoba and Saskatchewan had already established mothers' pensions and Alberta and British Columbia were on the verge of passing such legislation. She gave a detailed account of the methods used in Manitoba where the funds are raised by taxation, the province and the mnuicipality each paying half, and a great deal of the work in connection with the pensions is done voluntarily. Each case is investigated and unannounced visits are made by a supervisor to see that good use is made of the pension. Mrs. Coates suggested that if such legislation were passed in New Brunswick the Women's Institutes could look after much of the work. In reply to a question as to whether allowance for a housekeeper would be given to a man left widower with several small children, Mrs. Coates said that she thought such provision could be made. Mrs. Kuhring asked if the idea that his wife and family would be provided for in any case might not make the young head of a household less provident. Mrs. Hooper did not think this would be the case, quoting statistics to prove her statement. She also

TOOK SEVERE COLD

SETTLED ON CHEST.

Bad Cough for Weeks.

The cold starts with a little running of the nose, the head becomes stuffed up, but little attention is paid to it, thinking perhaps it will go away in a day or two.

You neglect it, and then it gets down into the throat and from there to the lungs, and it is a case of cough, cough, morning, noon and night.

However slight a cold you have you should never neglect it. In all possibility, if you do not treat it in time, it will develop into bronchitis, pneumonia, or some other serious throat or lung trouble.

Dr. Wood's Norway Pine Syrup is a universal remedy for those who suffer from any bronchial trouble. It stimulates the weakened bronchial organs, soothes and heals the irritated parts, loosens the phlegm and mucous, and aids nature to clear away the morbid accumulations.

Mrs. Wm. Kaye, Talmage, Sask., writes:—"Last winter I took a severe cold which settled on my chest. I had a bad cough for weeks. I got some medicine from our doctor but it did me no good. At last a friend advised me to try Dr. Wood's Norway Pine Syrup, which I did, and after using one bottle I found that my cold was better. I have recommended it to my neighbors, and they say they would not be without it."

Dr. Wood's Norway Pine Syrup is for sale by all dealers. Price 25c. and 50c. a bottle.

Manufactured only by The T. Milburn Co., Limited, Toronto, Ont.

said that, of 270 pensioned mothers' children, none had appeared in juvenile courts. Miss Alice Fairweather spoke of the method of administrating patriotic funds saying that she thought mothers' pensions could be dealt with similarly.

On the motion of Mrs. Hooper, seconded by Mrs. Coates, a resolution was passed and will be forwarded to the premier of the province and to Hon. Dr. Roberts, minister of public health ,and will also be brought before the convention of Women's Institutes in the fall. The resolution said that the Women's Institute of St. John being convinced of the desirability and need of pensions for widowed mothers of children asked that legislation be passed in New Brunswick authorizing such pensions.

Mrs. Lawlor referred to the fact that the rooms of the Institute in Union Street were open to charitable organizations free, and that she hoped they would be used to assist any movement for the betterment of the lives of women and children. She said that arrangements had been made for free classes in milinery, dressmaking, domestic science, first aid and home nursing.

The entertainment arranged was then given and greatly enjoyed. Miss McInerney sang, "Ring Out Sweet Bells of Peace," and as an encore, "Annie Laurie," and Mrs. Edmund Flewwelling recited a very amusing sketch entitled, "When Hezikiah Closed the Saloon."

Mrs. Lawlor then told of settlement work she had seen in Montreal and the methods of which she thought could be followed in St. John. She spoke also of the wrapping of bread in St. John saying that all should stand together to get some action taken in the matter and not allow themselves to be passed from board to board, getting no satisfactory answer on the subject. Mrs. Flewwelling told of a case where bread was being offered for sale that was not fit for consumption.

Mrs. Hooper described the systems of milk inspection in Montreal and Toronto, having particular praise to bestow on the Toronto authorities in this respect, as they have made pasteurization of milk compulsory and have ninety-two nurses under the board of health. She pointed out the great need for milk inspection in St. John and fo rmore education along hygenic lines.

The serving of refreshments and the enjoyment of a social hour brought the meeting to a close.

Let Nature Clear Your Blood

With pure, rich blood—a healthy stomach—and an active liver—you may laugh at disease, and, you may have all three by taking

Dr. Wilson's HERBINE BITTERS

This splendid blood medicine—made of old fashioned herbs—gives the system a regular "spring housecleaning"—regulates liver and bowels—cleanses the blood of all poisonous matter—tones up the nerves—and gives strength, vigor and a feeling of good cheer to the whole system.

At most stores. 35a. a bottle; Family size, five times as large, $1.

SOME RECIPES DEMONSTRATED AT RECENT SHORT COURSES HELD IN SUSSEX

CARROT SOUP

2 c. stock.
2 c. carrots.
4 slices onion.
2 c. milk.
2 tbsp. butter.
4 tbsp. flour.
Salt and pepper.

Cut carrots in small pieces and cook with onions in water 20 minutes or until tender, press through a strainer (there should be 2 c. stock) finish as vegetable sauce and serve hot.

CREAM OF TOMATO SOUP

2 c. Tomatoes.
⅛ tsp. soda.
2 tbsp. butter.
4 tbsp. flour.
Salt and pepper.
2 c. milk.

Stir tomates slowly one-half hour, press through a strainer, add soda while hot and water to make 2 c. stock. Finish as vegetable sauce and serve immediately.

CORN SOUP

1 can corn.
1 pt. water.
1 pt. milk.
1. tbsp. butter.
1 tbsp. chopped onions.
3 tbsp. flour.
Salt and pepper.
Yolks 2 eggs.

Cook corn and onion in water 20 min., press through a strainer (there should be 1 pt. stock and pulp) finish as vegetable sauce, add beaten yolks, cook 1 min., strain and serve immediately; eggs may be omitted.

GREEN PEA SOUP

1 pt. or 1 can peas.
3 c. boiling water.
1 pt. milk.
2 tbsp. butter.
2 tbsp. flour.
Salt and pepper.

Wash the peas and cool them in boiling water until soft, pres through coarse strainer (there should be one pint sock and pulp). Finish as vegetable sauce. If peas are fresh, pods may be cooked with them.

CLEAR SOUP

2 lbs. meat and bone.
1½ qts. cold water.
½ c. onion.
½ c. turnip.
4 cloves.
6 pepper beries.
1 tsp. mixed sweet herbs.
1 bay leaf.
1 sprig parsley.
1 piece celery root.
1 white of egg.

Cut the meat into small pieces and soak with bone in cold water 1 hour. Cook gently 3 hours, add vegetables finely chopped and seasonings. Cook 3 hours longer, strain, cool, remove fat and clear. Several pieces of lemon may be heated with stock if the flavor is desired. If part of the meat and vegetables are browned the color and flavor of stock are improved.

PORK CHOPS WITH FRIED APPLES

Wipe chops, sprinkle with salt and pepper, place in hot frying pan and cook slowly until tender and well browned on each side. Arrange pork chops on a platter and suround with slices of apples, cut ½ inch thick fried in the fat remaining in pan.

Full weight of tea in every package

RED ROSE TEA "is good tea"

Sold only in sealed packages

WARNING—

That pain in the back is a danger signal.

Pain in the back is one of the commonest symptoms of kidney trouble. It is Nature's way of telling you that your kidneys are tired, congested and need immediate assistance, or they cannot keep the blood stream purified.

You know the rest. Once the blood stream is poisoned, a chain of diseases follow, and you probably become an invalid. Be warned,—use

Gin Pills FOR THE KIDNEYS

and free yourself from the ravages of all Kidney or Bladder afflictions, Brick Dust Deposits, Painful Urinations, Backache and constant Headaches.

Gin Pills have brought relief to thousands—they will do the same for you. Try them.

50c a box. Sample box free on request.

189

POTATO SOUP

1½ c hot riced potatoes.
1 qt. milk.
2 sliced onions.
2 tbsp. butter.
1 tbsp. flour.
1½ tsp. salt.
¼ tsp. celery salt.
⅛ tsp. pepper.
Few grains cayenne.
1 tsp. chopped parsley.

Scald milk with onion and add slowly to potatoes. Make white sauce of mik mixture and remaining ingredients, excepting parsley, strain and just before serving add parsley. Cold mashed potatoes may be used and served with milk.

DRESSSED MEAT

Wipe meat, remove bone and stuff, place on rack in dripping pan and dredge meat and bottom of pan with flour. Place in hot oven to sear. As soon as flour in pan is brown, reduce heat and baste every 10 minutes. It may be necesary to put a little hot water in pan while meat is cooking. When about half done season with salt and pepper. For roasting allow 18 minutes to the pound.

STUFFING

2 c. bread crumbs.
2 tbsp. butter (melted.)
½ tsp. salt.
⅛ tsp. pepper.
½ tbsp. poultry seasonings.
¼ c. boiling water.

BROILING MEAT

Remove extra fat from the meat. Grease the broiler with some of the fat. Place meat in broiler and broil over a clear fire. Sear and then turn every 30 seconds. Chops should be cooked about 8 min. Season and serve on hot platter. In pan brailing keep the pan free from fat.

HAMBURG STEAK

Chop finely 1½ lbs. lean raw beef, add 1 tsp. salt, pepper and if desired, a few drops onion juice. Shape into flat cakes and pan broil.

KIDDEE

1¼ lbs. uncooked tough meat.
1 tbsp. grated onion.
1 tbsp. chopped parsley.
1 tsp. salt and pepper.
1 c. stewed and strained tomatoes.
1 tsp. butter.

Chop meat very fine, add seasonings, form into balls about the size of an egg, place in baking pan. Add tomatoes and butter. Bake in a moderate oven 30 min., basting 3 or 4 times.

NOTIONS FOR JUNE BRIDAL SHOWERS

By Laura V. Hamner

I wish one of my friends would marry soon, for I have deramed out the loveliest shower and I want to try it out while I am brim-full of enthusiasm over it.

I should send out invitations to a "Hit-or-Miss" Shower, telling my guests to send in their gifts early so that I might arrange them according to a certain scheme. I should place the mahogany clock in the kitchen cabinet, the boudoir-cap in the furnace-room, the percolator on the victrola, and the bronze book-racks in the bathtub. Of course they would be duly disguised so that no one should see them until the bride herself should enjoy them and should read the little messages which would probably accompany them.

I have planned to have a seat of honor for the bride. A little maiden all in holiday attire should enter rolling a small wheelbarrow painted white, with a pretty, fluffy bow on it. In the barrow would be a ball of cord of the color of the decorations and this would be rolled to the feet of the bride enthroned on her chair of state. She would then re-wind the ball, finding at intervals a card or slip of paper. This would be my adaptation of the "wonder ball" idea. Each card would tell her where she could find a gift and I feel sure she would sally forth after each discovery to return, bearing a new trophy. I feel sure I could make a charming afternoon party out of this plan because of the elements of originality, mystery, and informality.

If I should decide that the preceding would be insufficient to make a program for a party I should use the "Wishing Well." I would make a well of rocks around a deep vessel filled with punch and a tiny windlass and bucket would complete the preparations. Then I should tell my guests that this was one of those mystic wells where, if one drank, believing in the efficacy of the waters, all their wishes would come true. I would then demand, in Peter Pan style, that they give evidence of their faith by drinking and wishing the bride well. I believe that much amusement would result from the wishes expressed.

May had a kitchen shower for Alma the other day and the manner of presentation was especially pleasing to the guests.

We are not used to negroes in this section; many of us remember them as a part of our childhood, and so it was a real treat to see a fat colored woman come strolling into the reception-room, pulling a child's wagon, loaded with bundles of kitchen utensils. So cleverly was she disguised that it was not easy to believe that "Dinah" was our neighbor, supposed to be too ill to be present. The bride offered Dinah a permanent position as cook and the conditions of service were discussed, to the amusement of all the guests.

At a shower which I attended last Summer, the gifts were all wrapped,

"I Am So Short of Breath"

"IT MUST be your heart, Grand Dad."

"Yes, I suppose it is. I am getting old, you know."

"Oh, you are not so old. You have got run down after the cold you had and will be all right when you get your blood built up again."

"Well, I hope so, dear."

"You remember how weak my heart was, Grand Dad, when I used to be pale and anaemic. It was no joke for me to climb these stairs then."

"You are all right now, aren't you?"

"I never felt better in my life, Grand Dad, and if you will use Dr. Chase's Nerve Food for a while you will get strong and well, too. That is what cured me."

"But do you think that the Nerve Food is any good for old men like me?"

"I am sure it is. I often read letters in the newspapers from old people telling about what a great benefit it has been to them by enriching the blood and increasing their vitality."

As an example of what Dr. Chase's Nerve Food does for people of advanced years, here is a letter from Mr. James Richards, 73 Dundas St., Belleville, Ont., who is 89 years of age. He writes:

"I was suffering from a weakness of the heart, shortness of breath and frequent dizzy spells which used to force me to go and lie down for a time. I secured Dr. Chase's Nerve Food and received such splendid results that I continued its use until I am now feeling fine and am not troubled with these symptoms any more."

Dr. Chase's Nerve Food, 50c a box, 6 for $2.75, all dealers or Edmanson, Bates & Co., Ltd., Toronto. On every box of the genuine you will find the portrait and signature of A. W. Chase, M.D., the famous Receipt Book author.

"ALL IN" AS HE THOUGHT

Could Not Work or Walk Any Distance.

The efforts put forth to keep up to the modern "high pressure" mode of life in this age soon wears out the strongest system, shatters the nerves and weakens the heart. Thestrain of business, the cares of home and social life, cause terrible suffering from heart and nerve troubles.

The strain on the system causes palpitation of the heart, faint and dizzy spells, smothering and sinking spells, shortness of breath, etc.

The reconstructive power of Milburn's Heart and Nerve Pills is simply marvellous, and those whose health standard is below par, will find a course of them will soon recuperate their health and get back their mental and bodily vigor.

Mr. Oscar Tracy, Postmaster, Tracy Station, N.B., writes:—"Two years ago I was 'all in' as I thought; could not do any work, nor walk any distance. I had taken no medicine, but tried your Milburn's Heart and Nerve Pills, and found such benefit from the first box that I continued taking them. I am sixty years of age, am able to work every day, and feel fine now."

Milburn's Heart and Nerve Pills are 50c. a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

numbered and placed on a long table. With numbered cards and pencils in hand the guests went about attempting to divine the contents of the parcels by feeling them. When the bride was allowed to investigate, the guesses were checked off by the holders of the cards, and a prize was given the most successful.

Mrs. Davis invited a few of Elizabeth's most intimate friends to come at three, bringing a gift and and unhemmend tea towel. Bess had promised to come down at three-thirty to help with some committee work and so was not epectxing to find the merry crowd which awaited her.

She was met at the front door by the daughter of the house who gave her a card telling her to look on the library table for further directions. She found a bundle which was discovered to be some lovely table-linen and in the folds was a note telling her to look in the middle drawer of the dresser in "Mother's" room. And so she went from place to place, finding new treasures until the last one told her to go back to the reception-room and "talk it all over." As she revelled in her pretty things and discussed them with her friends who had followed her on her quest, they hemmed towels for her linen-closet.

The spinster of one party, who had long since changed the name of her "hope -box" to "oGodnes-knows-when chest," announced that she had abandoned all home of matrimony. In view of the fact that she had helped cheerfully to deck sweet girl graduates and countless brides and had bought rings and things for many a first baby, and that she had no possible claim upon the generosity and affection of her friends, she demanded a Consolation Shower. She wanted some of the handiwork of her friends to adorn her bachelor quarters. And that seems to me to be a pretty good plan.

MUSIC IN THE FARM HOME

Music is an elemental part of life —as Gladstone has said, "one of the most forcible intsruments for training the mind and spirit of man," and the advantages of this most charming of arts in home life must be obvious to all. Music has made enormous strides in its evolution as an art, and in its eectffs upon emotions and morals of the nation. The family life of a home, which makes music one of its chief recreations, is affected in many ways, a closer bond of union, of affection being found among its members. Happy the child whose lot is cast in a joyous musical atmosphere. There is thus implanted in his inner being a something which will help him to go through many trials with a brave and an unconquerable hope and faith. If mothers would but understand the digesence between music as a performance and music as a life element, they would not hesitate to give the children every possible chance to acquire a taste for this art which more than all the others stirs the vital forces by which one lives. One of the rst steps infi arousing an apreciation of music is to lead a child to listen. How much stress is laid in educational schemes upon teaching a child to observe, to see; how little upon teaching him to hear. The eye is a rule made dominant and much enjoyment is lost which a trained sense of hearing might bring. The greater part of children's time is spent in elaborate impersonation and make-believe, and the entire basis of their education is acquired through this directly assimiliative faculty. This applies most forcibly to music and gives to those who have the care of children an almost unlimited opportunity for developing musical expression. The charm of music is most far-reaching with the child who is either endowed by nature with the ability to respond to musical influence or has been trained in ear and heart to feel its effects, and in the latter case the sound reproducing machines of the modern day are playing an important part. Their value and efficiency within certain limits cannot be denied. WitWhin recent years wonderful improvements have been made in the method of recording and reproducing, and where the best machines procured and reproductions of the best artists provided, they will be found a very valuable aid in training a child's sense of hearing to an ap-

Night-Time Time-Pieces

THE movement for the electric clock in the Toronto City Hall was brought over from England 21 years ago. It cost *thousands of dollars*. And it showed time in the dark.

About the same time very wealthy men were carrying in their pockets another kind of a time-in-the-dark time-piece—a watch that sounded the time for them on a tiny gong when they "pressed the button." This striking watch was known as a "repeater" and cost from $150.00 up.

Now you can buy a guaranteed Ingersoll Radiolite, the modern time-in-the-dark time-piece, for as low as $3.00. Instead of the old exasperating striking mechanism to *sound* the time, the Ingersoll Radiolite *glows* the time. Genuine radium in the substance on the figures and hands does it.

It's the watch for up-to-the-minute-men, the leaders, the kind of men who get things before the crowd knows they are a necessity. The retailer has a complete line, including the $3 model pictured above. Now is the time to select. Look for INGERSOLL on the dial.

preciation of music. The reproductions of the world's best artists are available, and only such should find favor in the home. This phase of the question is deserving of careful consideration, but with cautious discrimination in the selection of machines and records, these forms of music will be found advantageous in training the musical tastes of the young, provided, of course, they are not perimtted to substitute the actual study of music.

SEVERAL PRACTICAL TESTS OF TEXTILES

To protect themselves in purchasing materials women should know a few practical tests to determine the content and value of materials. The following tests may be applied:

1. If water is dropped on cotton and linen goods, the moisture spreads rapidly on linen but will remain unabsorbed on the cotton ror some time. This is not always a sare test as cotton and linen are eoften heavily sizea with dressing, which prevents the water from being absorbed.
2. A much safer test may be made by dropping glycerene on cotton and linen. Linen will become transparent but cotton wil not be affected.
3. Crushing cotton and linen materials in the hands will show the difference in the materials as linen wrinkles more than cotton.
4. Cotton and wool mirtures when moistened, wrinkle more than pure wool materials.
5. Material may be tested by pulling out threads and examining the ends. Cotton fibres are short with fuzzy ends, while linen fibres are long with uneven ends, usually pointed. Wool fibres are short, kinky and stiff; fibres of reeled silk are long, straight and lustrous, while fibres of spun silk are short and easily broken.
6. Sizing may be discovered by rubbing the material between the hands to see if the dressing will come out. Washing will also remove dressing.
7. Each fibre has a characteristic burning test which may be easily distinguished.
   a. Cotton burns quickly with flame.
   b. Linen burns like cotton, but is not as inflammable, as it has less oil in the fibre and less air in the woven cloth.
   c. Wool burns slowly, gives off an odor like burnt feathers and leaves a gummy residue.
   d. Silk burns more slowly and with les odor than wool. It leaves a crisp ash. Silk leaves more ash when it is weighted.

A MOTH MYSTERY

Just why moths should be found in a kitchen pantry shelf, where there seems to be no place for them to harbor, has been a puzzle to me for years. The other day I chanced on what gave a partial solution. Almost every housekeeper has, tucked away in some safe corner of her pantry, a few dry yeast-cakes, which are suposed to keep indefinitely; but on close examination, I found one of them riddled with moth-worms, and several of the moths clinging to the surface. They were so near the color of the yeast cake that a casual glance would never have detected them.

MENDING STOCKINGS

Large holes in the heels and knees of socks and stockings, if mended as follows, will be found to wear longer, look neater, and be more comfortable than if mended in the usual way. Take some strong black net, rub out any stiffness with the hand, cut slightly larger than the hole, and tack neatly on the wrong side; then darn out and into the net on the right side until the hole is well covered. The darning will hardly be seen, and you will be dilghted with the results.

Chocolates- as a Dessert

"PASS the chocolates again, please." They certainly give a finesse to the meal, which is a most decided improvement over the customary heavy puddings or fancy pastries.

Good chocolates are quite the vogue now for the third course and as a tasty, profitable and beneficial dessert, their use is a most sensible custom.

The many occasions on which chocolates can be served with relish and appreciation make them almost a household necessity.

As delicate, delicious desserts—at afternoon tea—as a relish for luncheon—'mid the family circle in quiet hours—or at late suppers—chocolates may be served with excellent taste and good form.

Chocolates are not a luxury. They are energy-producing food and can be eaten in your home with benefit to both old and young.

Canadian-made chocolates have no superiors. Their high standards of quality and wholesomeness are obtained by purity in manufacture and the careful selection of all materials used.

Serve Chocolates as a Dessert.
They are a Splendid Food.

HINTS FOR MOTORISTS

by ALBERT L. CLOUGH • *Editor Motor Service Bureau Review of Reviews...*

REALIZING FUEL ECONOMY EXPECTATIONS

Faulty Adjustments Prevent Realization of Claimed Efficiency

Not infrequently it happens that a motorist who purchases a car, fails to obtain from it as high gasoline economy as he has been told in advance that he should secure or so high as other users of cars of the same make and model are known to be achieving. This is always a cause of dissatisfaction and chagrin, for it is natural for every owner to desire to do as well as anyone else in this regard. Some of the chief causes for low fuel economy are comprised among the following: Too rich running adjustment of the carburetor. Means should be provided for temporarily enrichening the mixture, when it is required, but the regular adjustment should be made while the engine is heated and should be a little leaner than that giving maximum pulling power. Lack of tightness of the cylinders, due to ill fitted pistons or rings, imperfectly seating valves and defective gaskets. Mistiming of the valves, including failure to open fully and close promptly and incorrect timing of the spark causing too early or delayed firing. Imperfect vaporization and mixture with air of the fuel supplied, due to faulty manifold construction, lack of heat supplied the intake system or too low cylinder wall temperatures, occasioned by too low cooling water temperature. Internal power waste, due to the negative work incident upon premature ignition, resulting from carbon incrustations of faulty jacketing. Unusual frictional losses, caused by inadequate piston lubrication attributable to oil of improper grade, quality or condition. Abnormal power losses in housings, resulting from lack of lubrication or from the use of unduly viscous lubricants and frictional resistances produced by brake bands which do not fully clear their drums. And by badly aligned road wheels.

It is always possible that the failure of an individual user to obtain from his car a fuel efficiency comparable witth that shown by other identical cars may not be entirely attributable to defects in the particular car and its adjustments, but may be the result of the manner in which the car is maintained and driven. Among operative errors which lead to fuel waste are the following: Driving long distances either at extremely high or at extremely low speeds. Both practices are very wasteful and a gallon of fuel goes a very little way under these conditions, as compared with what it does at 20 or25 miles per hour. Failure to run the spark as much advanced as practicable, resulting in the throwing away of much valuable heat energy. Faiure to change eto a lower gear when the engine has slowed down, under load, to beelow its economical speed, slipping of the clutch, for speed regulating purposes, instead of using the throttle, which results in substantial fuel loss due to engine racing. Racing the engine unnecessarily to warm it up, idling it when it might better be shut down and idling it unnecessarily fast. Failure to take advantage of the car's coasting ability, by throwing the gears into neutral and shutting down the engine on long down grades. Acceelerating with uncalled for rapidity, when starting and when under way and sacrificing expensively attained car momentum, by applying the brakes while still running at high speeed, instead of coasting up to the stopping point. Failure to conserve engine heat by keeping the radiato rshielded, thus increasing the waste of fuel at each start. Failure to always emeploy the leanest fuel mixture upon which the engine can be successfully run, after it is warmed, and carlesseness in leaving the carburetor air supply choked, after starting, longer than it need be. Even with a perfectly conditioned car, operative errors can reduce efuel efficiency pretty low, but combined with a car that is "out of sorts" the result of unskilled driving on fuel efficiency is appalling.

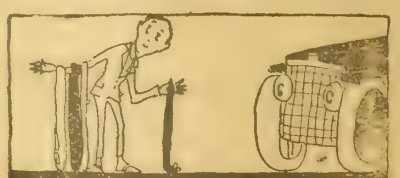
SEE THAT THE IGNITION SWITCH IS "OFF"

One thing about which many motorists are rather careless is the ignition switch. On cars having magneto and upon some cars equipped with the battery system, leaving the ignition switch on, when the engine is stopped, involves no risk except that it renders it easier for an unauthorized person to start the engine, but on all cars fitted with closed curcuit battery ignition and with most systems of open circuit battery ignition, neglect to open the ignition switch whenever the engine stops running, may result in the storage battery being exhausted if the oversight is not soon corrected. In fact, it may result in the injury or destruction of the ignition coil insulation. Automatic devices are used in some ignition systems to open the circuit, in case the switch is left closed, but these sometimes fail to act. In others a peculiar sound gives alarm when this condition exists, but this is not always heard or heeded. On many cars there is no safeguard save the carefulness of the operator. When an engine stalls and is not again started, when a meddlesome person throws the switch from off to on or when the switch is accidentally thrown into an open position, especially when a car is to be left idle for a long time, the battery is likely to bt discharged so that the engine cannot again be started. The only safe rule is always to see that the switch is off and locked in that position, when the engine is not running.

INNER TUBE INQUIRY

S. H. B. writes: I have ea number of very old inner tubes. How can I tell whether or not it pays to keep them?

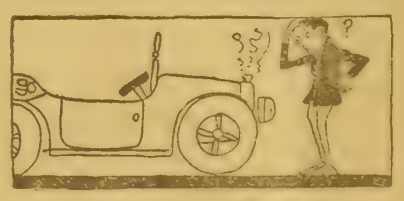
Answer: As long as a tube is capable of holding air and is not stretched so badly as t oform folds and become pinched in service, it may as well be kept and the utmost possible service obtained from it. Very little strength is required in an inner tube and an old or thin one may be practicaly as serviceable as a new one. Air tightness is an inner tube's only important qualification.



EFFECT OF BOILING RADIATOR

E. H. B. writes: Does it harm an engine ein any way when the water boils in the radiator and around the cylinders?

Answer: Boiling of the liquid in the cooling system cannot, in itself, do any harm to an engine, but the boiling may be an indication of something wrong with an engine, which may cause injury to it, such as an insufficient cylinder lubrication or a failing supply of water, which soon may entirely disappear and permit serious overheating to take place. Any unaccustomed tendency to boiling should be at once einvestigated.



REPAIRING A SCORED CYLINDER

W. S. asks: If a cylinder has been scored, so that a piston cannot be fitted tightl yin it, is there any possible remedy except reboring it and the rest of the cylinders?

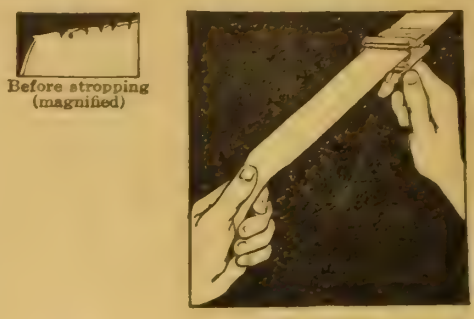
Answer: There are several processes in use for repairing "scorees" without enlarging the cylinder bore, which depend upon replacing the metal, that has been worn away, by means of alloy electrically welded in place or deposited electrolyitically. After this is done, the repaired portion is ground true with the rest of the bore. If acylinder is all right, with the exception of a definite score, such as made by a displaced wrist pin, such a repair as this, if successful, permits the use of the old piston and obviates the necessity of doing anything to the rest of the cylinders.

CHARGING BATTERY FROM FARM LIGHTING PLANT

W. L. writes: A neighbor of mine has one of the gasoline engine driven farm lighting plants and it occured to me that I might charge my auto battery from it and save taking it to town. If this can be done, please explain the method.

Answer: As plants of this kind generate direct current and as direct current is necessary for your purpose, you can readily charge your battery from this source. If this is a 3 volt outfit, each 40 watt lamp passes about 1 1-3 amperes and 5 of these will pass between 6 and 7 amperes. Arrange the

No edge without stropping



As the farmer becomes more of a business man, he finds a good personal appearance counts greatly in his favor in his dealing with other men.

He realizes that to have a first-class razor, and to enjoy head-barber shaves a razor blade must be stropped. Now, satisfactory stropping can't be done in the old way unless a man has acquired the knack. Not everyone can, and that's why men in increasing numbers are turning to the AutoStrop Razor.

Because of its self-stropping feature, a man can easily keep his AutoStrop Razor sharp. He is never at a loss for a keen blade, for he always has one. This and the fact that it is not taken apart for stropping or cleaning has led thousands of shavers everywhere to speak highly of the AutoStrop Razor to their friends.

If you want to see how enthusiastic men can really become about their AutoStrop Razors, just mention the matter the next time you're in town. The result may surprise you. Any dealer will sell you an AutoStrop Razor, strop and 12 blades complete for $5.00, with the understanding that if it doesn't please you, your money will be handed back without argument.

AUTOSTROP SAFETY RAZOR CO., LIMITED
AutoStrop Building, Toronto, Canada

AutoStrop Safety Razor

circuit so that the current that supplies these lamps also flows through your battery, making sure that current is passing in the right direction. The following test can be used: Dip the wires coming from the lamps and that from the other side of the circuit into a tumbler or water, containing a little salt. The wire giving off the more gas bubbles should be connected to the negative or (—) post of the battery. The wiring is simple; from one side of the supply circuit to one side of the bank of lamps, from the other side of the lamp bank to one side of the battery and from the other battery terminal to the other side of the supply circuit. There should be a switch included.

DERANGEMENTS THAT MENACE LIFE AND LIMB

The Front Wheels And Their Connections Bear Great Responsibilities

There are a great many derangements of car mechanism, which may occur at almost any time and leave a car and its passengers stranded upon the highway, inconvenienced, but in no way injured but, on the other hand, there are a few derangements or breakages, the occurrence of which to a car in raipd motion, is more than likely seriously to injure the passengers, to say nothing of wrecking the car. Every motorist should realize what these derangements are in order to be upon his guard against them. They are as follows: (1) Any derangement of the steering mechanism resulting in loss of direction control. (2) The loss of a wheel, causing the car to drop to the road upon one side. (3) The detachment of the forward end of the drive shaft, torque rod or distance rod and its consequent falling and catching the road, tending to overturn the car. Accidents due to all these causes prove serious in much more than direct proportion to the car speed at which they occur. (1) The breakage or disconnection of any part concerned in the steering function, resulting in the car's running wild or the sudden binding or locking of some part of the steering gear so that the car's course cannot be altered by the operator, are the two kinds of derangement. The first is the more common and is most likely to be occasioned by the accidental disengaging of the ends of the drag link (steering gear connecting rod). The greatest care should be taken that the ends of this are kept most securely fastened and indeed all the fastening devices in the steering gear should frequently be inspected. Perhaps the worst feature about a steering gear derangement is that the driver usually continues to try to gain control of car direction by the wheel after this has become impossible and fails to use the brakes in time to avert an accident. (2) The loss of a rear wheel is usually not serious under ordinary conditions, but the coming off of a front wheel is one of the most dangerous happenings conceivable. This may occur from the breakage of a wheel bearing, the loosening of locking devices or the fracture of the spindles that carry the front wheels. Extreme care as to the condition of bearings and the security of locking devices, will do much to minimize these dangers. (3) Some cars have means for catching such parts before they can touch the ground. Bad accidents have happened from this cause, but they are much less common than those due to steering gear and front wheel derangements.

TUNGSTEN BREAKER POINTS

C. J. P. writes: The contact points in the breaker-box of the car that I now own, are always black in appearance, although they operate all right. I have always been told that the points should be bright, in order to give good results. How about this?

Answer: These points, if used in connection with a battery system on a car of rather recent date are doubtless of tungsten. Points of this metal are gray and not white and glaze over with a dark film which however seems not to prevent their successful operation. In fact, many makers of ignition system, employing tungsten points, recommend that nothing be done to the points but that when they give serious trouble or are largely worn away,

that they simply be replaced. Tungsten is cheap enough so that this is not an unreasonable suggestion. One thing is certain, it is not incumbent upon the motorist to keep tungsten breaker points bright as if they were platinum (of which we shall probably see but few in time to come.)

TESTING PLUGS UNDER WORKING CONDITIONS

J. A. M. asks: Is there any way of testing a spark-plug to see how it will operate under working conditions, with compression acting upon it?

Answer: A plug tester can be bought or made, consisting of an air tight chamber made of pipe fittings, with a glass window, in which the plug to be tested is screwed. Air pressure is then pumped up in the chamber with a tire pump and the action of the spark can then be watched under compression. With most plugs a piece of mica can be placed between the points, of such size and so placed that the spark must pass around it to get from

one point to another. In the length of the spark path is made three-eights or seven-sixteenths-inch in free air, its resistance will equal that of the normal spark gap under compression and if the plug sparks throhgh this elongated gap its insulation is probably all right.

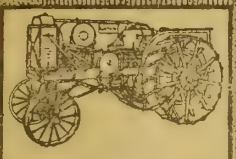
DRYING OUT DRAINED ENGINE

J. A. M. writes: I keep my car in a cold garage and draw off the cooling water every night. When it is brought in hot, is it necessary to run the engine, after lettng out the water, long enough to evaporate whatever liquid may remain in the system?

Answer: We do not consider it necessary or advisable to run the engine until the insides of the jackets are fully dried out. Moisture merely adhering to the inside walls of the cooling system can give no trouble from

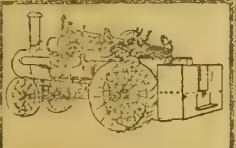
freezing, but pockets of water anywhere in the system may do so. Running the engine a while, usually shakes out what little water fails to run out through the drain cocks or brings it into the pump, from which it is expelled. If, however, you wish to run the engine to dry it out pretty thoroughly, you can safely operate it until the cylinder heads become too hot to touch with the hand for any length of time.

A Correct Lubricant for every Farm Machine

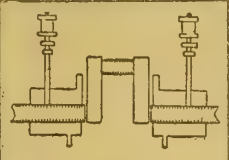


For Gasoline Engines, Tractor, Auto or Stationary
POLARINE OIL
STANDARD GAS ENGINE OIL
For Kerosene Engines Tractor or Stationary
POLARINE OIL HEAVY
POLARINE OIL A
IMPERIAL KEROSENE TRACTOR OIL
IMPERIAL KEROSENE TRACTOR OIL EXTRA HEAVY
(Recommended by many tractor manufacturers)

For Open Bearings of Farm Machinery
PRAIRIE HARVESTER OIL
—very heavy body, resists cold, won't thin out with moisture
ELDORADO CASTOR OIL
—a thick oil for worn and loose bearings



For Steam Cylinder Lubrication, whether Tractor or Stationary Type
CAPITOL CYLINDER OIL
—the standard product for steam cylinder lubrication



THRESHER HARD OIL
For Grease Cup Lubrication of Bearings, a clean solidified oil high melting point.

IMPERIAL OIL SERVICE
Talk over your lubrication needs with the *Imperial Oil man*. There is an *Imperial Oil man* near you and he is there for that very thing. You will find him well posted on farm lubrication and glad to be of service to you.

Proper Lubrication Increases Farm Profits.

Correctly lubricated farm machines do last longer. Correctly lubricated engines, trucks, tractors and automobiles not only last longer but they will do more work or go more miles at less fuel expense than those poorly lubricated.

Selecting Imperial Lubricants, the high qualities of which are recognized everywhere, is a step in the right direction. The next thing is to use the proper lubricant for each machine and each purpose.

There is no all-round lubricant. There is an Imperial Lubricant made especially for each need. A few recommendations are mentioned in the panels at the left.

All Imperial Lubricants can be promptly supplied in a size suited to your needs. They come in half gallon, one gallon and and four gallon sealed cans, in half barrels and barrels.

UNDERCHARGING OR OVER-CHARGING—WHICH?

Look Out for the Former in Winter and the Latter in Summer

So long as the generator keeps the battery fully charged, but still does not subject it to serious overcharging, an ideal condition prevails but, like most other ideal situations, this is seldom realized for any great length of time. Despite all the precautions taken, the average battery is either being undercharged or overcharged a great part of the time that its car is in service, and every motorist ought to know how to tell which of these two evils his battery is laboring under, at any given time, so that he may be able to act inteligently in bringing about more favorable conditions. Here are a few suggestions. A battery is undercharged in proportion as the density of the electrolyte in its cells fall below 1280 and toward 1150 and it is obviously undercharged when the lights suplied by it burn below their normal brilliancy and when the starter motor operates less actively than it should. On the other hand, a battery is being overcharged when it becomes decidedly hot, after a long trip has been made when an unusual amount of water is required to keep the cells filled and when the lamps burn too brightly and fail early. Undercharging is to be avoided for the obvious reason that it results in poor starting and lighting service, but also because it leads finaly to sulphatation of battery plates. Overcharging is to be avoided, because if persistently practiced, it results in the destruction of the battery (statements to contrary notwithstanding), it calls for unnecessary work in suplying water, wastes some fuel, shortens the life of lamps and causes needless wear and tear on ignition aparatus. Assuming there is nothing wrong with the battery or generator equipment, undercharging can be reduced by having the generator output increased by practicing economy in the use of lights; using the starter only after carburation and ignition conditions have been adjusted to insure prompt response from the engine; by running in second, when very low car speed is required, and providing auxiliary charging current from a rectifier or other outside source. Overcharging can be lessened by having the generator's charging rate reduced, but the most effective method is the provision of a switch, by means of which the generator can be stopped from furnishing charging current, when it is not needed—as on long daylight trips. Many manufacturers advise against such charging cut-offs, lest the careless operator leave the generator inactive when charging is necessary. However, the device, if used intelligently, is of great value in regulating the state of the battery.

INADJUSTABLE CARBURETOR

J. L. writes: I have come into possession of a 1911 car. There seems to be nothing wrong about it, but yet has hardly any power, running weakly and spitting back into the carburetor. Someone has suggested that the carburetor needs adjustment, but there is absolutely no means for adjusting the gasoline supply that I or the local garage man can discover. What is to be done in a case like this?

Answer: There have been many

cars built with inadjustable carburetors, the idea of the manufacturers evidently being that such carburetors could not be put into an inoperative condition by careless operators. This construction, however, prevents a carburetor from being conveniently made to handle present-day gasoline, as can one provided with adjustments. Your engine is not getting gasoline enough. Possibly you can obtain a larger jet from the makers of this carburetor, but more likely you will have to drill out the gasoline spraying passage slightly to give it somewhat greater capacity. By doing this carefully, you should obtain good results. Try a drill size very slightly larger than the present passage, and, if this does not prove sufficient, try the next larger size.

CUTTING LOUVRES IN HOOD

C. Writes: I have had a good deal of trouble from water boiling in the radiator of my car. There are no slits in the sides of my car's hood, as there are in so many others and I have wondered if having such slits cut would

result in any improvement in the cooling effect.

Answer: We hardly think so. These slits or louvres are not depended upon to let out the hot air; the space under the car floor being supposed to be of ample area to give egress to the air current, without serious friction. Louvres are used to improve the looks of the hoods and possibly to reduce the weight sligtly not to furnish added cooling effect. Perhaps you can increase the effect of your fan, make your radiator more active eby cleaning it out thoroughly, or do something that will stop this overheating.

MALTESE CROSS TIRES

MORE Comfort in motoring depends upon good tires than upon any other single item of equipment.

Maltese Cross Tires are an assurance of maximum comfort, satisfaction and mileage.

Stromberg-Carlson Telephone Mfg. Co.
10 Front St., East, TORONTO, CANADA

CAUSE OF RATTLING NOISE

H. C. asks: What is the most likely source of an annoying rattling at the forward end of my car, which occurs

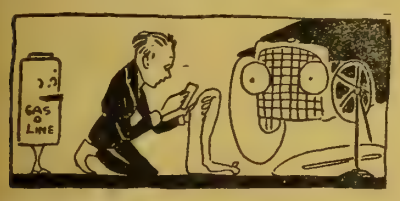
when driving over car tracks or rough places in the road?

Answer: Most likely it is in the steering gear. Looseness at the ends of the tie-rod, which connects the two wheels or at the ends of the rod which connects the steering device with one wheel, lost motion at the steering knuckles or loose bearing adjustment of the front wheels may cause this. Looseness of the hood upon its supports or lack of tightness at the front springs may produce such a noise.

TUBE PATCHING OUTFIT

S. P. T. asks: Everything considered, what is the best outfit for use in mending inner tubes, that can be carried upon a car?

Answer: We presume that the little portable vulcanizers would be called the best. These make use of prepared patches, each of which carries its own fuel, sufficient to furnish the heat required to vulcanize it. A vulcanized



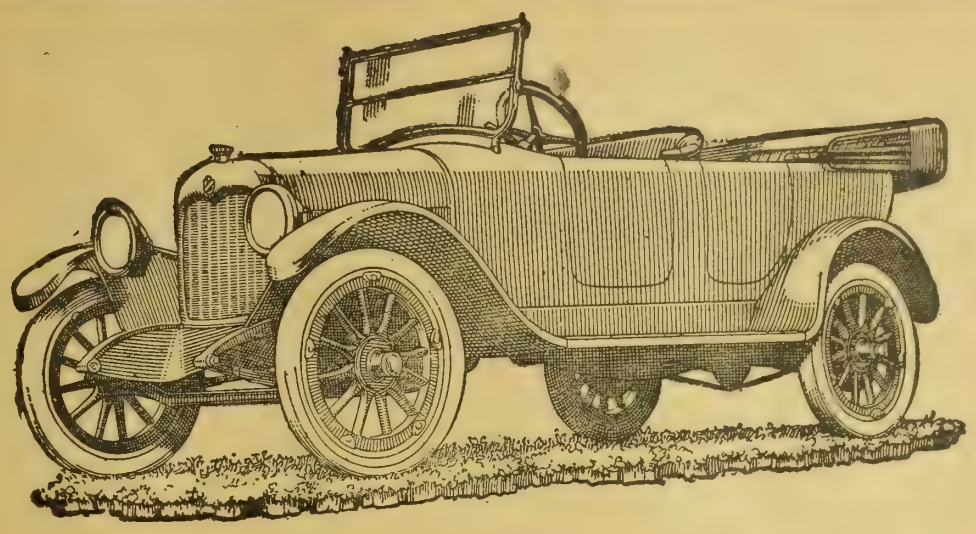
tube repair can be quickly made in this manner. Patches affixed merely by cement and not vulcanized give good results and such a repair is the quickest. These prepared patches, already cemented and requiring only to be moistened with gasoline and applied, are to be had of all supply dealers.

REPLACING SPILLED ELECTROLYTE

P. A. writes: I accidentally left out the filling plug of a cell of my storage battery and later found that so much of the acid had spilled that I could not see the top of the liquid. The lost liquid was replaced with distilled water, as the directions contained a warning neve to put anything else in

the cells. Since doing this, the cell does not test up to strength. How can I make it do so?

Answer: The caution against putting anything but water into cells applies only to cases in which water only and not acid has escaped. In your case, the acid electrolyite had escaped, in part, and putting in pure water diluted the remainder, so that its gravity was necessarily below normal. We suggest that you draw the liquid entirely out of this cell by means of a rubber tube on the end of the battery syringe, make up new electrolyte and fill the cell with it. You better test the gravity of the liquid in each of the other cells, average these readings and bring the new electrolyte to this value before putting it in, being sure ethat temperature differences are taken care of. Use P. C. sulphuric acid and distilled water in making the mixture and pour the former into the latter gradually, to avoid heating effects.



The Maxwell is a sensible buy for farmers—Why?

FARMERS more than any other class buy the Maxwell. They buy it for many reasons. But all these reasons come down to the one fact—the Maxwell fits the farmers' needs better than any other car.

It is a big, roomy, comfortable car. A family car. It is light enough to give the utmost economy in tires and gasoline. It is strong enough to stand country road driving. It is powerful enough for any rough going.

And it is completely equipped. No "extras" to buy.

But, above all, the Maxwell is a dependable car. Five years ago the chassis was designed—for rugged simplicity. Then Maxwell after Maxwell was built on this original plan—over 300,000 of them.

This chassis has been perfected, of course; but not changed. It was *right* five years ago. It is *right* to-day. Over 1000 refinements have been made. To-day's Maxwell is the best car our engineers *could* produce for farm service.

And this dependable chassis has been robed in new beauty. 24 refinements in appearance in this year's model make it a car you'll be proud to own. Beautifully upholstered. Distinctive in style.

Not the least of the sensible reasons for buying the Maxwell, for getting Maxwell value, is Maxwell Service. There's a Maxwell dealer near you—anywhere in Canada.

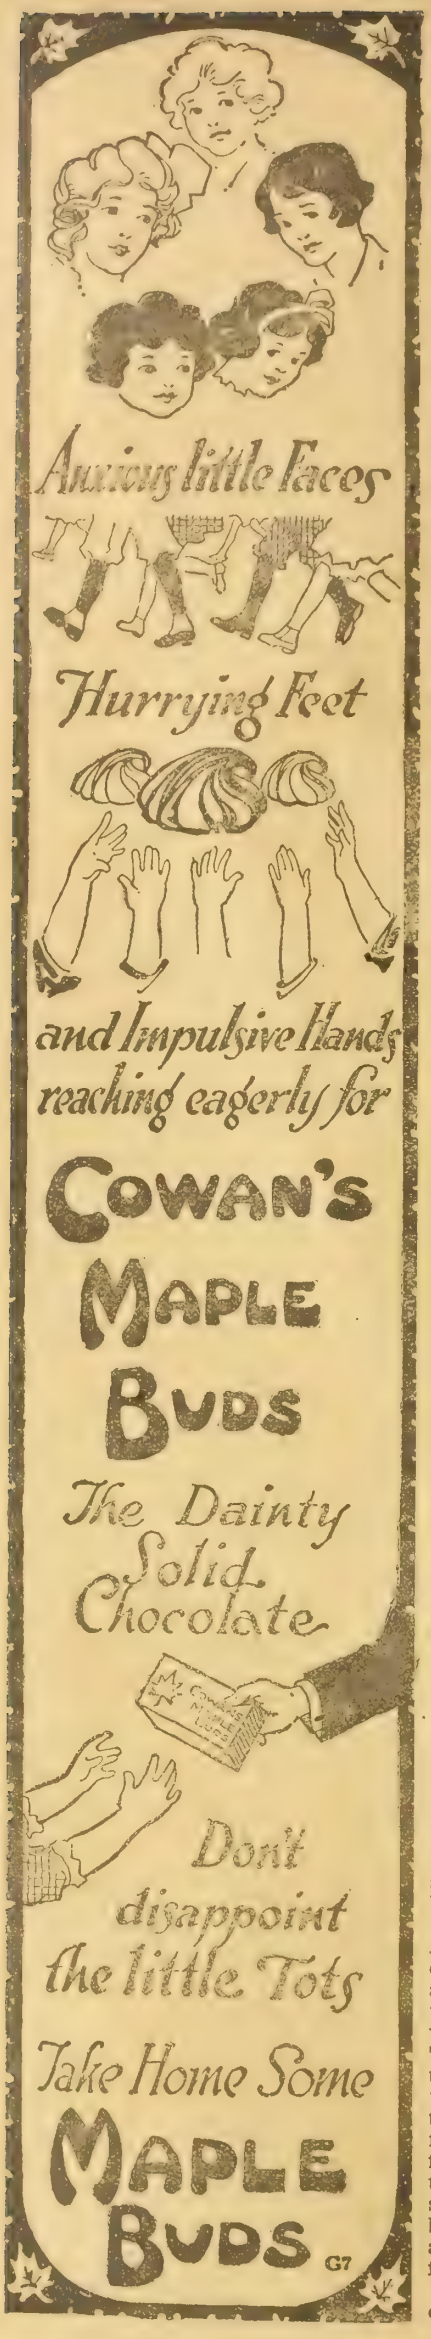
Don't spare the ax and saw in the old orchard when the trees are dying and blowing over. Very often an orchard with care can be made productive. Save the old orchards, as many of the old reliable varieties are very scarce.

When the top of an apple tree is heavily pruned the greatest increase wil loccur in the growth and vigor of al lother parts of the tree. The cutting away of the growth will send new strength into the weaker parts where most needed.



MARITIME DAIRY SCHOOL

(Continued from page 863

previous to the war and that the late Dr. James, then Dominion Agricultural Commissioner was strong in the presentation of the advantages of the same, and while the idea was favourably discussed by the members of the Governments of each Province it required considerable educational work to present the economic advantages of the same to a large percentage of the people of the different Provinces. He also suggested that at that time Dr. James was favourable to a substantial grant from Ottawa for the same as an interprovincial organization.

The question was discussed at length by all the committees and resolutions were passed and representatives appointed to make the necessary investigations with the authorities at Ottawa for their sanction and support before it would be presented for the consideration and support of the Governments of the three Provinces and a sub-committee was appointed to carry out this part of their work and to call the whole committee together again when a definite report was got from Ottawa.

In the meantime Mr. Coleman acts as permanent Chairman and Mr. MacKay as Secretary.

It is to be hoped that the committee meet with satisfactory prospects in their undertaking as there is no branch of farming that the Maritime Provinces are more favourably adapted to than Dairying, and the business cannot develop much faster without just such an institution to impart and spread the necessary education connected with it and to properly train the men to act as leaders in all the diffrent branches of the work.

MAKING SUGAR FROM SUGAR BEETS.

We publish herewith an article on making sugar from sugar beets and suggest that all interested in making sugar at home, save this copy for future reference, as it may be convenient to have handy directions for making sugar from the beets grown in one's own garden. We were a little credulous at first about making sugar at home, but have the assurance of some of the best chemists of the country that it is entirely feasible.

So far as our information goes this syrup that results from the home process of manufacturing, contains a small suantity of betaine, a chemical found in sugar beets. This chemical is not poisonous but gives a characteristic taste or flavor to the syrup which makes it different from pure sugar syrup. However, this syrup is excellent for cooking which in these days of scarcity of all kinds of sweetening will be a welcome addition to the family stores. Sugar beets may be grown wherever garden beets will thrive. But in buying seed be careful to get the seed of the genuine sugar beet, not seed of the so-called sugar beet grown for stock feeding. The genuine sugar beet only is suitale for sugar making. Seed of it may be obtained from any reliable seed house. Two varieties that have been recommended to us by a Canadian seed house, are Klein Wanzelbener and Vilmorin.

The United States Department of Agriculture issued recently a bulletin describing a method of making sugar at home from ordinary sugar beets that may be grown in any locality where soil and climate are suitable. The following information in the matter is taken from the bulletin in question. Readers desirous of making their own syrup next fall should carefully lay aside these instructions for future reference, as it is claimed by the experts of the department that a satsfactory syrup for home use may be made from beets grown on the farm and with such equipment as may be found in any home.

The first step in making beet syrup consists in topping and cleaning the roots. The crowns should be cut off at the point of the lowest leaf scar. The reason for this is that the crown or upper part of the beet contains a large part of the salts taken from the soil in the process of growth. It is desirable to have the syrup as free as possible from these mineral salts, which, if present in too large quantities, would render the syrup unpalatable.

In cleaning the roots, they may be placed in a tub or other suitable receptacle and covered with cool water, to loosen teh dirt and to make the roots more crisp. After soaking for a few minutes, until the dirt is loosened, they should be thoroughly scrubbed. A coarse brush with stiff bristles or wire is useful in this work. After the roots are thoroughly washed they should be cut into thin slices. A 3-bladed kraut cutter securely fastened on the top of a barrel, has been found very satisfactory. The upper head of the barrel should be removed so that the beet slices will fall directly into the barrel. If a kraut cutter is not at hand, any slicing device, the simplest of which is a butcher knife, will be satisfactory. The slices should be very thin. The thinner the slices the more rapidly the sugar is extracted.

A bushel of beets will make approximately 2 bushels of slices, which should be placed in a barrel and covered at once with hot water. About 10 gallons of water will be required to cover them. An excess of water should be avoided, since it would increase the amount of evaporation required to reduce the solution to the desired consistency. If boiling water is used, the temperature of the slices will reduce the temperature of the water to about the proper degree, from 158 to 176 degrees Fah., for the extraction of the sugar. The barrel should be covered with several thicknesses of canvas to hold the heat. The sliced beets should be permitted to soak for about 60 minutes, and the barrel

Greasy sputterings and drippings!

GOLD DUST

The Busy Cleaner

MADE IN CANADA

should be agitated from time to time without uncovering it.

The water should now be drawn off and strained through several thicknesses of cheesecloth. No pressing is required to remove the juice from the beet. If the barrel is provided with a faucet near the bottom for the purpose of drawing off the liquid, it will be found convenient. The soaking does not remove all the sugar from the beet slices, but by far the larger part of it is extracted if the slices are sufficiently thin and the water is of the proper temperature. The resulting liquid is of a light brown color, with a sweetish bitter taste. The refuse beet slices are a valuable feed for chickens, hogs, and other live stock.

The juice may be placed in a kettle or other convenient receptacle, where it should be heated slowly until it has evaporated to the proper consistency. It should be noted that evaporation depends upon the temperature, the surface of the liquid exposed, and the condition of the air above the liquid. In experiments made by the experts of the department a 30-gallon copper kettle was used. Slow boiling is important in making beet syrup, and several hours will be required to complete the evaporating process. This may be done on the kitchen stove, or a kettle may be suspended in the open and fire should be maintained sufficiently hot to keep the liquid boiling until the proper amount of evaporation has taken place to produce the desired consistency of syrup. Some people like a thin syrup, while others prefer a thick product. In boiling the juice care should be taken to avoid burning. A little experience will enable one to accomplish the boiling without scorching the syrup.

While the boiling is progressing, a scum will rise on the surface of the liquid; ths should be removed carefully by means of a skimmer. An old-fashioned milk-skimmer, or a basin with or without small holes in the bottom, will accomplish the desired result. The skimmer should, for convenience, be provided with a suitable handle. A small straight or curved stick of proper length, split at one end and slipped over the edge of the skimmer, will serve the purpose. The object in skimming is to remove the scum as completely as possible without wasting any of the liquid. This operation removes the strong, beet-like flavor and leaves a wholesome and palatable product. The removal of the scum tends also to keep the liquid from boiling over. As soon as the syrup has reached the desired consistency and has been skimmed carefully it may be placed in cans or bottles for future use. It should be canned or pottled while hot and tightly sealed or corked to prevent molding.

The syrup produced from beets is dark in color. This would be objectionable if the product were placed on the market, but for home use it probably would not be regarded as serious, in view of the quality of the product and the simplicity of the process. Any method of bleaching or otherwise removing the dark color would require considerable skill and some outlay of money. The desire being to produce a palatable and nutritious article of food which can be made in almost any home, it is the aim to avoid all technical and expensive methods. The flavor of the syrup is pleasant. It contains the pure juice of the beet root and is a wholesome and nutritious food, which to a certain degree should be helpful in reducing the sugar bill.

Beet syrup may be used for all purposes for which other syrups or molasses would be employed, especially for table use; for example, on buckwheat cakes, in making dark-colored cake, or in preparing certain kinds of home-made candy. If the evaporation is carried far enough and the syrup is allowed to stand, a dark sugar will settle out. This sugar will be found very satisfactory for home use in cases where refined sugar is not necessary, such as in making pies or dark-colored cake.

GRAIN TROUBLES

Oftentimes seed treatment is not practiced because of a more or less prevalent notion among some farmers that seed injury is quite likely to result after treatment. In fact, this notion may be exerting more influence in preventing the spread of recommended seed disinfection methods, than the actual work connected with the treatment or the cost of formaldehyde, which amounts to about two (2) cents an acre.

When treating seed, it is well to have in mind the following points: (1) Do not dry too slowly after treating as this may cause injury to germination. (2) In case spring grain is treated during cold weather, best results will be obtained by seeding it promptly, because of the danger of freezing the moist grain. (3) Poor stands, often claimed to be due to seed injury, may in reality be due to the use of insufficient seed, or the use of seed showing a low germination test in the first place. (4) Treated grain is swollen and the rate of seeding should be increased accordingly. (5) Seed disinfection (formaldehyde) increases the yield by eliminating certain other diseases, stripe disease of barley for example. (6) Weather condtions cannot be foreseen, and the only safe course for the farmer to pursue is to treat every year. Smuts found on the following grains may be controlled by seed treatment: wheat, oats, barley, rye, millet, and sorghum. —James Godkin, Colorado Agricultural College, Fort Collins, Colorado.

Insist on the best seed. Buy tested seed only. How otherwise is it possible to be sure of its quality? How otherwise can one be certain of its purity and germination? Don't destroy the effects of your labor in preparing the soil by planting inferior seed. If you insist that your dealer sell you tested seed only, and that they be tagged, he will in turn insist upon better seed from the wholesaler and growers. The demands of the purchaser are readily heeded by the merchant.

"To be progressive and successful every man must be to some extent an experimenter. To inquire; to observe; to measure; to compare; to weigh in the balance and decide; that is a man's job. Each time a man does it he gains in strength of character, and in power of achievement."

SOME PECULIARITIES OF COWS

(Continued from page 869)

later in the progress of milking but its formation always indicates a lack of complete and perfect process in manufacture. The cells which remain attached to the basement membrane go into the business of manufacturing fat and other normal constituents of milk.

Production of Casein, Fat and Sugar

The production of the casein, fat, sugar, and other ingredients of cow's milk is an original manufacturing process and not merely filtration from the brood, for there is no milk sugar, no butterfat, and no casein in the cow's blood when it reaches the udder. The milk manufacturing cells simply take certain elements from the blood and put these elements together in such a way as t oform the fat, the casein, the sugar, etc.

There are two processes in milk formation. First: Milk cells, lining the alveoli, or tiny milk cavities, or portions of those cells, undego fatty changes. . The cell manufactures the fat which accumulates in the free end of the cell. The free end of the cell changes into a tiny fat globule and separates from the portion in contact with the basement membrane. The portion thus left we will call the parent cell. This parent cell then lengthens again and develops another fat cell, at the free end, which in turn separates from the parent cell. You will thus see that this butterfat production is a process of moulting, or shedding; just as the hair sacs produce and shed hair, The fat globules escape into tiny cavities within the udder and thence to the milk cistern at the base of the teats.

Influences Affecting Milk Secretion

The production of milk is clearly a manufacturing process. Excess of fat in the diet does not materially increase fat in the milk under normal conditions. Material used in milk formation comes directly from the lymph fluid contained in the little spaces surrounding the clusters of milk cells. The lymph receives raw material from the blood and simply passes it on to the milk forming cells over the fence, i. e., on the other side of the basement membrance.

The quantity and quality of milk depends, first of all, upon hereditary peculiarities of the indivfdual cow. After this it depends upon food. It depends upon how long the cow has been milking, upon how long she has been carrying her calf, upon the condition of her nervous system, and to a very great extent upon the quantity of blood passing through the udder.

After the first pregnancy occurrs the milk glands are stimulated to active growth and the little bottle shaped cavities are developed and lined by milk forming cells. Each cell is a little flattened oval shaped body much too small to be seen with the naked eye. Late in the period of pregnancy there develops a scanty and imperfect secrteion of fluid which later becomes the colostrum, or first milk drawn after delivery.

Nervous System Control

It is very evident to the practical dairyman that there must be some nervous relation between the cow's nervous system and her process of milk secretion. You all know that nervous disturbances of any kind are apt to check the milk flow. A crowd of strangers passing through a stable, where high type and highly organized dairy cows are kept. sudden noises, rough handing, all check the process of milk formation. The only possible connection betweeen the noise outside the animal body and the process of milk manufacture inside her body is by way of the nervous system.

A bond of connection and intimate sympathy between the udder and the womb is also found in the common blood which flows through both organs.

Soon after the foetus is removed from a mother's body, growth and development of the udder stops, and active milk secretion begins. This general statement holds true again in the reverse condition when a second pregnancy occurs and a new foetus is developing within the mother's body. There is a marked tendency to the development of udder structure in preparation for another period of milk production and a tendency to check milk secretion.

One futher interesting point may perhaps be mentioned in this study of condition affecting milk formation. Pressure in the milk ducts and milk cavities within the udder checks the manufacturing process in the individual milk cells. As soon as milk contained in the udder—and therefore pressure started upon the se cells—is removed, then secretion starts again; in other words, the pressure brake is released and the wheels begin to revolve again. The act of emptying the cow's udder and merely relieving pressure upon the milk forming cells therefore amounts to a natural stimulus of milk cell activity.

Summary

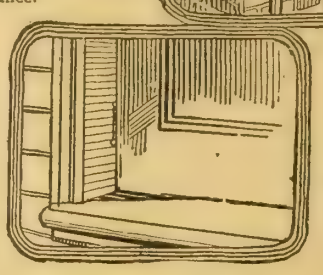
The production of milk is a process of original manufacture, not a mere filtratoin from the blood. There is no butterfat or casein or milk sugar in the blood which comes to the udder.

I have endeavored to show the process of forming the fat globule in the elongation and rupture of the milk forming cells lining the alveoli and by this rupture furnishing the fat globule. The other milk materials are alos formed from the lymph fluid which surrounds the alveoli.

The influences affecting milk secretions are hereditary, food, period of milking, stage of pregnancy, condition of the nervous system and especially the quantity of blood passing through the udder. I have endeavored to explain a very interesting relation between the unborn young and the development and preparation of the udder for the next process of milking, also the checking effect which some chemical substance within the blood of the unborn young animal has upon actual milk formation. When the young animal is born and therefore separated from the mothre's body these relations cease, and development and preparation of the udder ceases. At the same time ethe chemical substance which restrains milk formation is removed, the brake is released and the active secretion of milk is begun. Finally pressure of milk within the udder checks secretion; removal of this pressure stimulates or at least permits secretion.

The amount of milk produced depends upon the amount of blood flowing through the udder. The amount of blood depends upon the size of the blood vessels, and size of blood vessel is controlled by the nervous system. The composition of the milk depends

Expensive repairs can be avoided by taking a little pains to protect the surface of the metal trim on your buildings. Remember how it is exposed. Keep it well protected and rust won't have a chance.



If we ever stopped to count the number of feet that pass up and down the doorsteps of our homes, we would appreciate better what their surface has to stand. Once the wood gets really worn, through lack of protection, it never can be made to look as good as new. A tough coat of protection saves the surface.

THIS ANNOUNCEMENT is issued by the Canadian Save the Surface Campaign Committee, for the purpose of educating the public in the preservative and protective value of Paint, Varnish and Allied Products for the Conservation of Property, and has received the approval of the Canadian Trade Commission in the following words:

"The realization of the above objects will lead to employment during the Reconstruction Period and bears our entire approval.

THE CANADIAN TRADE COMMISSION

CANADA

Commissioner.

Why Some Furniture Never Seems to Grow Old

OLD in its associations, yes. Old in that beautiful intimate sense of affection we sometimes have for even inanimate things—but not old in the sense of shabbiness.

Protection of the *surface* is the secret of the continued good looks of furniture It is the surface of the furniture that bears the burden of constant wear. It is the surface we *see*. As long as the surface is kept protected good furniture stays good and grows more valuable yearly.

And furniture, after all, only illustrates a point.

It may be something very different—the metal trim of your buildings or the steps of your house. What use will do to your furniture, rust will do to the metal and scuffling feet to the doorsteps. Again, what these things will do the elements will do to your wooden house, or to stucco, or sometimes even cement.

"SAVE THE SURFACE AND YOU SAVE ALL"

Surface gives the first foothold to wear, rust, decay, and all destruction. The gospel of thrift as applied to the things we own is the gospel of preserving the surface. 10.

Flying Sparks die out on Brantford Asphalt Roofing

The best way to economize

The best way to economize is to buy roofing with the quality put into it that will make it last longer than ordinary roofings.

Asphalt is one of the most enduring materials known to science—especially if the hard, brittle asphalts are blended with the soft, pliable kind, which produces an asphalt of remarkable toughness, elasticity and durability. This is what we do to get the very best grade of asphalt for the saturation and coating of

Brantford Asphalt Roofing

The saturation of the felt in Brantford Roofing is done at the high point of more than 350 degrees. This makes the saturation complete, every fibre of the felt being soaked through and through with the asphalt.

Brantford Asphalt Roofing does not evaporate under the heat of the sun. Neither does it absorb moisture, freeze or crack. It is also a wonderful fire-resistant, the insurance companies classifying it as a non-combustible. Farmers need not hesitate to put it on barns or other buildings close by railroad tracks, because flying sparks from locomotives or threshing engines that fall on Brantford Asphalt Roofing are harmless and quickly die out without injuring the roofing.

If the interior of a building should catch fire, a Brantford Asphalt Roof acts as a blanket and helps smother the fire. It never sends embers flying through the air to spread a fire.

Brantford Asphalt Roofing has been on the market for many long years—long enough to have proven its lasting quality beyond question. The first roofs covered with it are still doing yeoman service in resisting rain, snow, hail, frost, heat and wind.

Farmers who have roofed one building with it, choose it for the next building requiring a lasting roof. Unlike most other things, Brantford Asphalt Roofing has had a very small advance in price since the start of the war. By enlarging our output and installing new labor saving machinery we have lowered the cost of production, which helps offset the increased cost of raw materials. You need, therefore, not postpone doing the necessary roofing this spring on account of a price consideration. The outstanding value of Brantford Asphalt Roofing, considering to-day's conditions, makes roofing with it a real economy.

Brantford Asphalt Roofing is made in three thicknesses. No. 1 is 60 lbs. per square. No. 2 is 70 lbs. No. 3 is 80 lbs. Both surfaces are sanded, which adds to the weight and durability of the roofing.

Brantford Rubber Roofing

has the same high quality asphalt saturation and coating as Brantford Asphalt Roofing, but it has a smooth rubbery surface instead of being sanded. It is also in three weights.

No. 1 is 40 lbs. No. 2 is 50 lbs. No. 3 is 60 lbs.

Leatheroid Roofing

Slightly lower quality than Brantford Rubber and used for same purposes. Has a leathery surface. Exceptionally good roofing at a low price. 35 lb., 45 lb., and 55 lb. weights. Samples and prices mailed on request.

Standard Mohawk Roofing

This roofing is made of same materials as Brantford Asphalt but is lighter in weight. It is the best quality of any low price roofing on the market. It is a standard that has been tested for years and given entire satisfaction. Sanded on one side. One weight only—40 lbs.

Climax Sheathing Paper

A tough kraft paper coated with high-grade asphalt. For use between footing and foundation of a building, between foundation and wall, between foundation exterior and the earth, below basement cement floors, underneath floors in houses, on walls before lath and plaster are put on—unequalled for damp-proofing and wind-proofing purposes.

primarily upon the hereditary peculiarities of the cow.

The composition of blood for milk production depends upon the amount and character of food received, thoroughness of digestion, and thoroughness of obsorption from intestines into the blood. It should be understood that when we speak of an efficient producer, either a steer producing beef or a cow producing milk, and say that this animal has large digestive capacity, we should really mean large power of assimilating and using digested food. Actual experience and experiments do not indicate that as a rule there is so much difference in actual digestive ability as there is in ability to assimilate.

The amount of milk produced, assuming an abundance of blood and abundance of nutrition in the blood and a dairy tendency, depends upon the actual number of healthy epithelial or milk secreting cells for an udder of given size depends upon the relative proportion of the gland tissue and connective or frame work tissue is presumably a matter of heredity except as the udder is affected by injury or disease

Finally ability to digest large amount of dry material, the tendency to dairy assimilation, the capacity of large flow of blood through the udder, the tendency of a large number or gland cells within the udder, and the tendency to relatively large proportion of gland tissue as compared with connective tissue are all matters hereditary, fixed by a long line of intelligent breeding.

THE HORSE'S PRAYER

"To thee, my master, I offer my prayer.

"Treat me as a living being, not as a machine.

"Feed me, water and care for me, and when the day's work is done, groom me carefully so that my circulation may act well, for remember: a good grooming is equivalent to half a feed. Clean my feet and legs and keep them in good condition for they are the most important parts of my body.

"Pet me sometimes, be always gentle to me so that I may serve you the more gladly and learn to love you.

"Do not jerk the reins, do not whip me when I am going up-hill. Do not force me out of the regular gait or you will not have my strength when you want it. Never strike, beat or kick me when I do not understand what you mean, but give me a chance to understand you. Watch me and if I fail to do your bidding, see if something is wrong with my harness or feet.

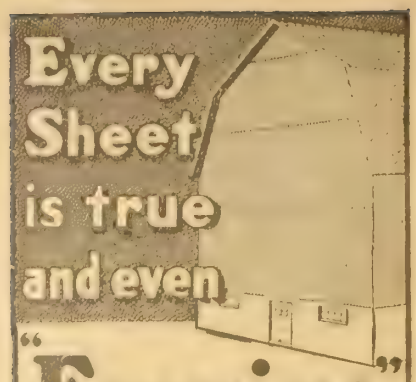
"Don't draw the straps too tight; give me freedom to move my head. Don't make my load too heavy, and oh, I pray thee, have me well shod every month.

"Examine my teeth when I do not eat; I may hava some teeth too long or I may have an ulcerated tooth and that you know is very painful. Do not tie my head in an unnatural position or take away my best defence against flies and mosquitos by cutting off my tail.

"I cannot, alas, tell you when I am thirsty so give me pure, cold water frequently.

"Give me a little more time at the watering trough. Take consideration about the bit that is in my mouth, and that many times I am out of breath when you offer me the chance to drink.

"When I'm wet with sweat, after a hard day's work, cover me with a blanket till I get dry. You have trained me t obe useful for you on the farm, and the only reward I ask to feel happy and contented, faring sumptuously each day with well chosen feeds, and to thee alone will be all the profit, praise and glory."



"Empire" corrugated Iron

"EMPIRE" Corrugated Iron is made with deep corrugations fitting closely and snugly; it makes a splendid, strong, rigid wall that withstands all storms. Remember—building with Metal gives you fire-proof, weather-proof and lightning-proof buildings.

Our "Metallic" building materials—the "Quality First" kind—may cost a little more than other building materials, but they're permanent. "Eastlake" Galvanized Shingles; "Metallic" Ceilings; "Metallic" Rock and Brick-face and Clapboard Siding; Roof-lights and Ventilators, Silo Tops, etc., save you money.

MARKETS.

CHARLOTTETOWN

Beef, demand good, 20c to 22c lb. by carcass.
Veal, 16c to 18c.
Hogs, dressed, 22c. Alive, 19c.
Lamb, none.
Mutton, 20c lb.
Beef Hides, 17c lb.
Sheep Skins, $3.00 to $5.00 each.
Calf Skins, 30c lb.
Potatoes, 80c to 85c per bushel in bulk. Demand good.
Carrots, $1.75 to $2.00 per 100 lbs. Scarce.
Turnips, 40c per bushel of 50 lb. Scarce.
Parsnips, none.
Oats, 82c to 85c per bushel. Supply fair. Demand good.
Cornmeal, $4.00 to $4.25 per sack.
Bran, $2.40 per sack. Very scarce.
Oatmeal, $5.50 per sack.
Middlings, $2.50 to $2.75 per sack.
Cotton Seed Meal, none.
Oil Cake, $3.50 to $3.75. Demand good.
Buckwheat, none except seed.
Ontario Flour, $11.85 to $12.00 in wood.
Manitoba Flour, $12.15 to $12.25 in wood.
Chickens, none.
Fowl, none.
Turkeys, none.
Geese, none.
Butter, Creamery, 55c to 58c. Demand good, but price falling.
Butter, Dairy, 48c to 55c, supply increasing.
Cheese, none except imported at 32c per lb.
Eggs, demand good. Supply good. Price 45c to 46c.
Hay, (pressed) $20.00 to $22.00 per ton.
Straw (pressed) $8.00 to $10.00 per ton.

THE PROVISION MARKET

Montreal, May 26.—There was no further change in the live hog situation today, the tone of the market being firm, with a steady demand for what supplies were available on spot, and sales of selected lots were made at $21.50 to $21.75 per 100 lbs. weighed off cars. A fair trade in a wholesale jobbing way continues to be done in dressed hogs, and prices were maintained, with sales of abattoir fresh-killed stock at $30.50 to $31 per 100 lbs.

There were no new developments in the condition of the market for smoked or cured meats, prices being firm under a good steady demand for supplies for local and country account, and this, coupled with the large movement for export, prevents any accumulation of stock on spot. In a wholesale jobbing way sales of 8 to 10-lb. hams were made at 39c to 40c per lb., 12 to 15 lbs. at 37c to 38c, and heavier weights at 35c to 36c. The market for bacon is more active than that of hams owing to the fact that the consumption of the former is larger than the latter, and sales of breakfast bacon were made at 43c to 44c per lb., Windsor selected bacon at 46c to 47c, and Windsor boneless bacon at 48c to 49c. The trade in barrelled pork is quiet, with Canadian short-cut in a jobbing way quoted at $56 to $58 per barrel.

The market for lard remains firm under a good demand for supplies for domestic and country account, and a fairly active trade was done in a jobbing way in Canadian pure leaf grades at 34c per lb. in 20-lb. wood pails, and at 35c per lb. in 1-lb. blocks, while American compound lard sold at 27c per lb. in 20-lb. wood pails.

The receipts of provisions today were 2,570 packages lard, 2,691 boxes hams and bacon, and 5,101 packages tinned meats.

Chicago, May 26.—Provisions rose despite considerable weakness in the hog market. The upward swing of grain gave impetus to the advance. Prices closed with gains of 15c to 25c. Future quotations were:

	Open	High	Low	Close
Mess pork, per bbl.:—				
May		$54.50	$51.15	$54.50
July		$50.10	$49.25	$50.10
Lard, per 100 lbs.:—				
July $31.25		$31.62	$31.20	$31.62
Sept. ...$30.80		$31.32	$30.80	$31.32
Short ribs, per 100 lbs.:—				
May		$29.25	$29.10	$29.25
July $27.25		$27.75	$27.25	$27.75

Cash prices closed:—Pork, nominal. Lard, $34. Ribs, $28 to $28.75.

MILLFEED AND ROLLED OATS

Owing to the more liberal supplies of bran and shorts an easier feeling has developed in the market, and prices have declined $1 to $2 per ton with sales today of car lots of bran at $42 and shorts at $44 per ton, ex-track, while sales of small quantities in mixed car lots were reported at $43 to $44 for bran and at $45 to $46 for shorts. There was no change in other lines of feedstuffs and the market on the whole was fairly active under a steady demand. Sales of feed cornmeal were made at $68, mixed grain moullie at $60 to $62, pure barley meal at $60, mixed moullie at $54 to $56, dairy feed at $48, and oat middlings at $44 per ton, including bags, delivered to the trade. The demand for rolled oats continues quiet and prices are unchanged with broken lots of standard grades quoted at $3.90 to $4 per bag of 90 lbs., and Golden cornmeal sold at $5.15 to $5.30 per bag delivered to the trade.

COUNTRY PRODUCE

Montreal, May 26—The strength which has characterized the egg situation for some weeks past now still continues to be the main feature, and prices in the country this week have scored a further advance of 2c per dozen, and dealers are now paying 49c per dozen f.o.b. shipping points, and it is reported that even higher figures than this have been realized in some instances, and in addition to this purchases of straight car lots were made at 49c per dozen, f.o.b. shipping points in Manitoba, and these eggs with freight added will cost 52c per dozen laid down here. In sympathy with the above the domestic market today was stronger, and dealers in some cases advanced prices 1c per dozen. The demand for home consumption continues good, and an active trade was reported in a jobbing way. The receipts of eggs today were 5,024 cases, as against 7,829 for the same day last week, and 2,677 for the corresponding date a year ago.

We quote wholesale jobbing prices as follows:

Selected eggs.....54c to 55c
Straight gathered.....52c to 53c
No. 2 eggs.....49c to 50c

There was no important change in the condition of the market for maple product. but the feeling remains very firm on account of the somewhat limited supplies available on spot. The demand for maple sugar for shipment to the United States continues good, and it is reported that sales of some round lots have been made at country points. The trade on spot in a jobbing

The First Line of Defence

A plentiful supply of ammunition is the first line of defence against the enemy. When waging war against the Potato Bug army, make sure that your first line of defence is impregnable by using Munro's Pure Paris Green—the only ammunition you'll need. When the first Potato Bug appears, spray the plants with a liquid solution of this old reliable Killer, and the enemy will be destroyed and your potato crop saved.

MUNRO'S PURE PARIS GREEN

is a fine fluffy, rich green powder made to Government standard. It has been killing potato bugs for years, and this year will kill more than ever, because more people will use this old standby to make sure of getting a good crop of potatoes. Be sure you get Munro's from your Hardware, Drug, Grocery and General Store.

13

way is fair, with sales at 26c to 27c per lb. as to quality. The demand for maple syrup is steady at $2.15 to $2.25 per tin of 13 lbs., and at $1.75 to $1.85 per tin of 8½ lbs.

There is a steady demand for small lots of beans for domestic account, and a fair trade is passing in a jobbing way at firm prices with sales of Ontario hand-picked at $4.50 to $4.75, and Quebec beans at $3 to $3.50 per bushel, ex-store. The trade in car lots is rather quiet on account of the fact that buyers of such are fairly well supplied for the present, and prices are unchanged, with Ontario hand-picked quoted at $4.25 per bushel ex-track. In sympathy with the other lines of grain peas rule very firm, but the demand is still somewhat limited, with Ontario boiling stock quoted at $3.50 to $3.75, and Quebec peas at $3 to $3.50 per bushel, ex-store.

The condition of the market for potatoes is unchanged, prices being firmly maintained on account of the continued small offerings and the good steady demand for the same for local consumption, and sales of Green Mountains in a jobbing way were made at $2.50, and Quebec white at $2.25 per bag of 90 lbs. ex-store, and car lots of the latter were quoted at $2 to $2.10 per bag of 90 lbs. ex-track.

A good steady business continues to be done in dressed poultry for local consumption and for shipment to outside points, consequently the market is fairly active, with a firm undertone, but there is no change in prices to note.

We quote wholesale prices of cold storage poultry as follows:

Choice turkeys, per lb.	48c to 50c
Milk-fed chickens	45c to 47c
Ordinary chickens	40c to 43c
Fowls, heavy	37c to 38c
Fowls, light	33c to 34c
Ducks, No. 1	48c to 50c
Ducks, No. 2	45c to 46c
Geese	31c to 32c

Chicago, May 26.—Eggs, unsettled. Receipts, 48,541 cases. First, 43c to 45c; ordinary firsts, 41½c to 43c; at mark, cases included, 42c to 43½c; storage packed firsts, 45½ to 46c; extras, 46c to 46½c.

New York, May 26.—Eggs, firm. Receipts, 20,803 cases. Fresh-gathered, extras, 51c; fresh-gathered firsts, northern section, 48c to 49c; southern section, 47c to 48c; State, Pennsylvania and nearby hennery, browns, 52c; do. gathered browns and mixed colors, 47c to 51c.

THE BALED HAY MARKET

The tone of the market for baled hay remains strong under a good demand for all offerings and sales of small lots for local account of good No. 2 timothy were made at $38 to $40, No. 2 timothy at $36 to $37, and No. 3 timothy at $34 to $35 per ton, delivered.

TO FREE STOCK FROM DISEASES DISINFECT STABLES

That regular disinfection of the stables is not a common practice in Canada is sufficient evidence that farmers do not appreciate the importance of the health of their animals. Such diseases as tuberculosis, abortion, scours, blackleg, glanders, hog cholera, etc., take enormous toll from farm revenues. Again parasites such as lice, ticks, etc., each year cause the waste of enormous amounts of expensive fed to say nothing of the losses in production of milk, meat, and young stock.

One of the most important factors in cheap and healthy wintering of animals is clean quarters and no quarters can be kept clean and free from disease and parasites without disinfection at least twice annually.

The basis of disinfection is direct contact. Disease germs under a layer of manure, srtaw or dirt, cannot be killed by average disinfection. Hence the first step is the thorough cleaning out of the barns, scraping (and washing, if possible), all walls and floors, and sweeping dirt, dust and cobwebs from walls and ceilings. Wooden floors should be repaired and earth floors renewed with a layer of clean soil.

What Disinfectants to Use

(1.) Sunlight. This is the cheapest and one of the best. Every stable should have at least six square feet of glass per mature head of horses and cattle, and one-quarter this amount for calves and mature hogs. Sunlight induces cleanliness, health, comfort and greater profits.

(2.) Whitewash: A good whitewash applied hot to ceilings and walls covers and kills germs and parasites. It is advisable to add drug disinfectants, such as carbolic acid, if the barns have housed diseased animals. Apply with spray pump or brush.

(3.) Drug Disinfectants: All floors, gutters, and mangers should receive extra care. Disinfect by soaking thoroughly with one of the coal tar distillates such as Kresa, Zenoleum, Creolin, etc., etc., applied in water solution 3 per cent to six per cent. varying with strength of disinfectant. Apply wtih spray pump or sprinkler and brush in.

Thoroughness in the above disinfection is most important.

The intelligent stockman intent on maintaining healthy stock finds it wise to disinfect mangers and feed passages more frequently. A light spraying monthly will suffice.

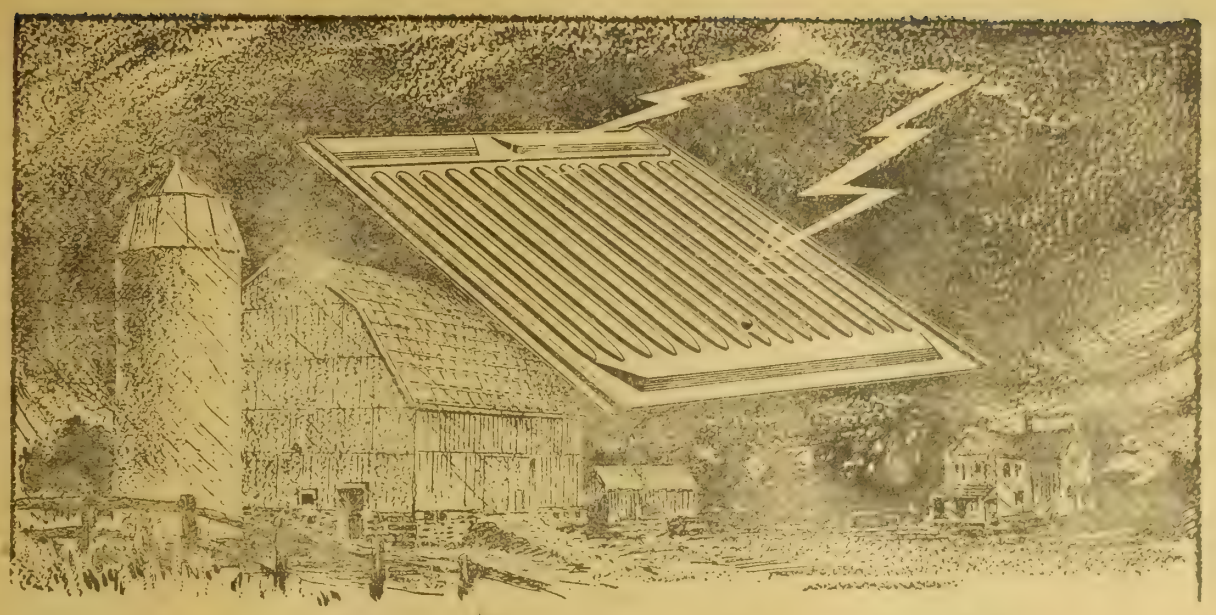
Practice proves that disinfection is cheap insurance and an investment yielding a high rate of interest. If Canadian farmers unitedly will but realize this, animal disease and losses therefrom would decrease 20 per cent. per annum.

BOARDING COWS EXPENSIVE LUXURY

A dairy cow that is not paying for her feed is truly a slacker, and should be eliminated from the herd at once.

Do you have any such cows in your herd? Do you keep a record of the number of pounds of butter fat produced per cow. If you do, doubtedly the slackers have already been eliminated. If you are one of those who do not keep record and tests of each individual animal, how do you know which cows are mere boarders and which cows are paying for their feed? Many times the cow giving the smaller amount of milk will average higher in butter fat than the cow giving the larger amount of milk. At the present high prices for feeding stuffs it is a serious proposition to be keeping cows that are mere boarders.

Keep accurate records of each individual cow; know for yourself which cows are paying and which are not. If a record is on hand when you offer your good stock for sale it will add greatly to the price you will receive.



Sure Protection From The Fiercest Lightning

LIGHTNING is a permanent menace to the farmer whose buildings are inflammable. Whenever the sky blackens with the gathering thunder-clouds and the vivid streaks of destructive lightning cut through the gloom he may expect at any moment to see his barn catch fire.

But not so the farmer whose buildings are Pedlar-roofed.

Pedlar's "George" or "Oshawa" shingles, properly grounded, present a surface of solid steel, which takes the lightning stroke and conducts it harmlessly to the earth, where its force is dissipated and lost.

Every year hundreds of thousands of dollars are lost by farmers in Canada through burned buildings, which also entails an almost incalculable loss of valuable live stock and season's crops. And the majority of fires are due to lightning.

Every year the lesson is learned too late by many farmers who have put off the re-shingling with Pedlar steel that they know is the policy of security.

Why take needless risks?

Why aid the elements in destruction?

A Pedlar-shingled roof is not only the safest roof you can have, but in the long run it is also the cheapest, for not only does it repel lightning and resist fire from any other cause, but it cannot rot or decay. It is the roof that endures—fire-proof, storm-proof, time-proof.

And it is easy to put on—big, generous, shingles, with the simplest and most effective lock ever invented.

Look into it! Write us for full details and prices if your local dealer cannot supply.

COMMON AILMENTS OF SHEEP

(Continued from page 871)

by castor oil. Death usually results unless lambs are closely watched.

Forage Poisoning

At this time of year we notice many inquiries in farm papers relative to death of sheep from unknown causes. One of these is forage poisoning. For the past 13 years this disease has come under my notice. Forage poisoning is more prevalent where silage is fed, though it occurs with any kind of feed or pasture. The first symptom noticed the sheep holding head a little to one side; one ear dropping and sheep unable to eat or drink; excessive flow of saliva; very nervous; seems inclined to place head against rack or some other object. Death usually results in from two to seven days. I have known some suffering with this malady to live 12 days. As no preventive or cure for this has been found death usually results. Veterinarians recommend Epsom salts, but it isi impossible to successfully administer any treatment owing to paralyzed condition of throat. I have given the salts by inserting a rubber tube into throat. Nux vomica in eight-grain capsules every six hours has proved beneficial. If any reader of this article has found a cure for forage poisoning, kindly give same in these columns.

PRESERVATION OF FENCE POSTS

It is a well established fact that the life of fence posts can be doubled or even trebled by the use of some form of creosote treatment. When applied to the softer woods the length of life is further increased. Creosote may be applied to fence posts in three different ways, all of which have proven very satisfactory.

The brush method is the simplest and also the least effective, the creosote being applied to the post with the ordinary paint brush. This is not a very satisfactory method due to the fact that the preservative does not penetrate to hardly any depth. To have results at all satisfactory by using this method the creosote should be heated nearly boiling hot when applied.

The dipping method.—The posts are just dipped in boiling creosote and immediately removed. This method has advantages over the brush treatment, due to the fact that the cracks and crevices are completely filled with the preservative.

The open tank method of treatment is by far the most successful of the three. When treating by the open tank process the posts are allowed to remain in the preservative for a period of two to six hours, during which time the creosote is kept boiling hot. They are then removed and left to cool in another "cooling tank" or left in the original tank until cool. In this way the wood becomes thoroughly saturated, effecting an efficient preservation of the post. The effect of treatment in the life of a post is shown in the following table:

Life of Fence Posts

	Untreated Years	Treated Years
Ash	6	25
Basswood	4	27
Boxelder	4	27
Bur Oak	12	27
Catalpa	17	27
Cottonwood	3	26

FARMER'S LIFE EIGHT YEARS ABOVE AVERAGE

The United States Department of Labor published recently a bulletin on the cause of death by occupation which is an authoritative work on the subject and gives a great deal of interesting information for insurance companies and the public generally. The department gathered data of 94,269 deaths of occupied white males and of 102,467 deaths of white females at 15 years or over. From these it was possible to work out a table showing the average age of death by occupation, the period covered being from 1911 to 1913, and the records studied being the mortality experience of one of the largest insurance companies carrying risks in all parts of the United States. The following table was compiled.

Males

	Average age at death. Years.
Clerks and office assistants	36.5
Enginemen and trainmen	37.4
Plumbers	39.8
Compositors and printers	40.2
Teamsters, drivers, chauffeurs	42.2
Saloon keepers and bar tenders	42.6
Machinists	43.9
Longshoremen and stevedores	47.0
Textile-mill workers	47.6
Iron moulders	48.0
Painters, paperhangers	48.6
Cigar and tobacco workers	49.5
Bakers	50.6
Railway track and yard workers	50.7
Coal miners	51.3
Laborers	52.8
Masons and bricklayers	55.0
Blacksmiths	55.4
Farmers and farm laborers	58.5
All occupations	47.9

Females

Clerks and office assistants	26.1
Store clerks and saleswomen	28.0
Textile-mill workers	33.9
Dressmakers and garment workers	42.0
Domestic servants	49.1
Housewives and housekeepers	53.3
All occupations	51.1

BAD CONFORMATION IN HORSES

(Continued from page 873)

little or no lameness while running straight out, but on turning them sharply round they can be easily detected.

Locating the Cause

When once the examination has discovered the suspected limb, the locating of cause is the next duty. Any spot that shows unnatural heat, tenderness on pressure, or swelling in any part of it, will generally guide in the decision as to the nature of the disease. If the discovery cannot be made by this means, the horse should be put to a sharp trot for half an hour and then left in the stall to cool off for twenty minutes, and then brought out again. This method rarely fails to show up the trouble, and it will overcome quite a number of the tricks that are practised by some horse dealers in reducing or hiding lameness in horses they have to sell.

FARMS LOSING SOIL FERTILITY

How Wasteful Methods are Checked.

While the spring-time work on the farm progresses the soil is the subject of the hour, and its wonderful properties may well move us to admiration. It is the direct source of the entire vegetable, animal, and human world,

A quaint U.E. Loyalist House on Bath Rd., near Kingston, Ontario. Built 1793 by Wm. Fairfield, a pioneer of Ernestown. The house has been occupied for four generations and is in a fine state of preservation.

A 126-Years War

HOW many successive times have the warring elements beaten upon this house, in the 126 years since it was built?

No one can say, but everyone can see the wonderful preservation of this house, through surface protection, despite all it has gone through in well over one hundred years.

If equally well protected, our modern houses should last as well. So will property of almost any kind—from a city garage to a country barn—from an office desk to a library table, or the metal trim of buildings, or your front hall floor.

Some surfaces may need one kind of surface protection, and some another, *but they all need surface protection.*

It is at the surface that trouble begins, rust that attacks iron—decay that attacks wood—wear that attacks surfaces subject to friction. All these allies of destruction hunt for an opening *at the surface.* Surface is the frontier—the point of attack.

It is when we once picture all the agents of property deterioration as an ever-ready enemy waiting to spring at any opening offered, that we appreciate the significance of the expression;

"SAVE THE SURFACE AND YOU SAVE ALL"

THIS ANNOUNCEMENT *is issued by the Canadian Save the Surface Campaign Committee, for the purpose of educating the public in the Preservative and Protective value of Paint, Varnish and Allied Products for the Conservation of Property, and has received the approval of the Canadian Trade Commission in the following words:*

"The realization of the above objects will lead to employment during the Reconstruction Period and bears our entire approval.

and well deserves the title of Mother Earth. In its formation it has undergone changes through countless ages, and these changes are still proceeding under the influences of frost and rain, cultivation and manuring. Man has not studied it long enough to make his statement of its formation from absolute knowledge, but if he will study the geological formation he will see that at one time the rich tracts of land were destitute of vegetation. We can conceive of it as being simply rock in some form, which was gradually decomposed by the action of plant life, growing plants of the lowest form, then higher and still higher, and becoming developed into forest and prairie rich with the stored fertility of uncounted ages, until man came to harvest the crop.

Retaining its Fertility

Only by following nature's way can fertility be maintained and restored, using the same things over and over again. It takes nature a long time to bring it back to fruitfulness after man has robbed it. Under nature's processes there is a slow and gradual increase of fertility, the humus supply increased by decayed vegetation, and the mineral elements—potash, phosphorus, and lime—by the gradual decomposition of the rock. The farmer who adopts a method of farming that will enable him to imitate nature will be on the road to good husbandry. It is quite possible to cause soil exhaustion, the cereal crop growing continuously removes the plant food in soil very rapidly if necessary elements be not augmented artificially. The amount of phosphoric acid and potash abstracted from a soil by 30 bushels of wheat or oats is about 9½ lbs. phosphoric acid, 15 lbs. of potash, and 35 lbs. of nitrogen. But rotation of crops enables the farmer to diversify his farming methods, furnishing a natural supply of manure, which, if intelligently applied to the land, will more than make up the losses in fertility from selling a portion of the grain and live stock. This is the reason for rotation of crops. Nature, too, it will be observed, mixes her grasses, one variety predominating one year and another the next. Bacterial agencies tear the fallen forest leaves, the decaying grasses, the dead roots and limbs to pieces, resolve them into their original elements, which the new crop takes up, and so it goes on time with end. Study the forest and the tracts of land still in nature's keeping and imitate their thrift and your land will not lose its fertility.

The Prodigal at Home

With respect to the conservation of the greatest of our natural resources, the elements of the soil, every citizen is interested, because from the soil comes the food of everyone, but the farmers are interested above all others, for the cultivation of the soil is their occupation, and from it they derive not only their food but all their income. The resources of the soil form the principal part of their capital. In wasting the fertility of the soil or in exhausting it without taking steps to restore the elements they are taking from it in each year's crop, they are acting the part of spendthrifts. If such a course is persisted in there always comes a day of reckoning, when not only in the ledger of the farmer, but also of the nation the balance is found to be on the wrong side.

.oM.c andx t,nu y.ofie etaoin etaoinn May 27, 1919

Agriculture is the foundation of all real and enduring progress in a nation, for it not only produces what is essential in existence, but it breeds the men necessary to build up a nation. The men who by reason of strength of character and intellectual pre-eminence take the lead in public affairs, in professional life, and in scholarship, are, as a rule, removed not more than one generation from ancestors who tilled the soil. A strong prosperous rural population is the surest guarantee of a nation's future, and the possession of such a population depends upon the maintenance of the fertility of the soil.

Desolation's Warning

There are well known facts in history that prove that such fertility will not endure without strenuous and well directed effort. The giant cities of Bashan thickly studded a land once fertile, now a wilderness made desert by wasting methods. That part of Asia from which Xerxes drew those vast armies that he led against Greece was then the homes of a dense population whose mainstay was agriculture. Today these lands are, comparatively speaking, deserts. The granary of the Roman Empire, the once fertile lands by the Red Sea, became barren through successive cropping, and remained so for centuries, but Britain by her administrative ability has reawakened life among their sunken and wretched populations in utilizing the water of the Nile to court again to activity the resources of nature in the soil and grant that land a fresh lease of life. These all point to the vital importance of conserving the resources of the soil —resources whose neglect not only affects the interests of the farmer, but also endangers the welfare of the nation from the King on the throne to the lowliest worker in the national hive.

Save Money and Labor

—and increase the volume of work done on your farm by installing the Fairbanks-Morse Type "Z" Engine.

It does the work of several men and eliminates the worry and expense of ordinary farm labor. No matter what type of farm you have there is a "Z" Engine that suits your requirements.

You are sure of the "Z" because it is the standard engine that was designed to do its work quicker, better and more economically than any other engine.

The "Z" operates on the cheapest of fuels—the 6 and 3 Horse Power on gasoline, coal oil (kerosene) or distillate—the 1½ H.P. on gasoline only. It is simple in construction, compact, easy to move about the farm and efficient because it develops more than rated power.

Ask your local dealer about this engine. He stands behind it and gives you a service that insures you satisfaction.

Investigate the "Z" today. Ask for demonstration of the

65 CENTS MAY EARN 100 DOLLARS

Smut diseases in wheat, oats and barley exact a toll of 16% of the total pield. In other words, many fields of oats, which should produce 40 bushels to the acre of well matured grain are cut down to 33. The other 7 bushels are lost through smut.

There is a simple and certain remedy—the treatment of the seed with formalin solution. Get one pint of formalin, costing 65c and pour it into 30 gallons of water. Then dip the seed in bags into the solution long neough to saturate it. Leave standing an hour or two, then spread out to dry, avoiding the dusty barn floor.

The 30 galon solution will treat 50 to 75 bushels of grain, enough to sow 25 acres, and the extra yield will probably run up to 150 bushels.

Make Them Worth More

NOW, of all times, you must get more work in return for every bushel of feed.

PRATTS ANIMAL REGULATOR saves needless expense, because your horses will get more nutriment out of less feed and work steadily all season. Cows give more milk—hogs fatten quickly. Use it for all your stock.

Money Back if Not Satisfied.

Volume 24. SUSSEX, NEW BRUNSWICK, JUNE 10, 1919. Number 17.

The Use of Disinfectants to Destroy Disease Germs Essential on Every Farm.

The average stockman and farmer does not realize the importance of thoroughly disinfecting his premises following an outbreak of contagious diseases. There is apparently a widespread lack of information regarding the germicidal power of various substances, commonly termed disinfectants. There is also a lack of knowledge concerning practictl and economical methods, and the reappearance of a contagious disease on premises from which it was believed to have been eradicated may frequently be traced to careless or imperfect work in connection with the cleaning and disinfection of the place.

This article has therefore been prepared with a view to emphasizing the importance of thorough disinfection of contaminated biuldings and to point out some of the most reliable disinfecting agents together with the methods for their application.

The Necessity for Disinfection

It is well known that micro-organisms, or germs, vary in form and other characteristics and that for each disease of an infectious nature there is a specific germ.

If these germs could be confined to the animal body and die with it there would be no such thing as an infectious disease. Unfortunately, however, they are thrown off by the animal through the excretions and lie in the earth, in the litter of stables, upon the floor and walls, and in cracks and crevices. Here they may remain and maintain their virulence for an indefinite period, ready at any time to be gathered up by an animal in its feed or to be blown about in dust and drawn into the lungs.

For example, we have tuberculosis in cattle and glanders in the horse. In the former disease the causative agent is a rod-shaped germ (bacillus tuberculosis) which is about one-thousandth of an inch in length. Cattle affected with tuberculosis pass myriads of these germs with the manure, and it is not difficult to understand how in the average stable they would have little difficulty in finding many lodging places. In glanders the causative agent is another rod-shaped germ (bacillus mellei) about the same length as the tuberculosis germ, but somewhat thicker. A characteristic of this disease is the foundation of ulcers in the nostrils and other portions of the body, from which there is more or less discharge laden with the glanders germ. And here, again, it is not difficult to understand how one diseased animal may contaminate extensive premises.

Some of these minute forms are vegetable organisms, in fact, these vegetable parasites are the cause of some of the most destructive diseases, and some of them are very difficult to destroy, for the reason that they contain spores. A spore may be likened to the seed of a plant, for it bears about the same relation to the bacillus that a garin of wheat does to hte plant proper.

As the plant may be destroyed and the seed remain latent for an indefinite time, so destruction of the bacillus may be easily accomplished while the spores remain unharmed and retain life for weeks or months.

An example of this class of organisms is seen in the agent which causes anthrax (baccillus anthracis.) Ordinary methods for the destruction of the baccillus will not destroy the sopre as well, and thus anthrax becomes a most difficult disease to eradicate. Upon farms where animals have died from anthrax and the carcasses have been buried instead of destroyed, repeated outbreaks of the disease may occur from time to time, possibly extending over a period of several years. This condition is due to the existence of the very resistant spores, which under favorable circumstances are carried to the surface of the earth and become infecting organisms—much as the seed of a noxious weed, after remaining in the soil during the winter, finds the condition favorable in the spring and develops into a plant—except that these minute forms of life multiply with the most wonderful rapidity.

Thus it is that our increased knowledge regarding micro-organisms or bacteria as the cause of many animal diseases has emphasized the importance of disinfection.

The Nature of Disinfection

The work of disinfection is based upon recognition of the presence of disease germs, and disinfection means the act of destroying the cause of the infection. In other words, disinfection is a removal of the cause, and it will be clear to any practical man that in dealing with disease any effort which stops short of a complete removal of the cause is most unwise and unprofitable. To those unaccustomed to the work, disinfection may seem a most complicated process. Any approved method, however, is comparatively simple when carried out care, fully, although like many another procedure it is one in which attention to details counts for much. It is important to bear in mind that the causative agents of many diseases are extremely small and may remain for an indefinite time in dust, cracks, and crevices of buildings, so that efforts aiming at eradication of disease from contaminated premises must be thorough in order to be effective.

Disinfectants

In the work of disinfection, nature has provided man with a most valuable ally—sunlight. It is well known that the direct rays of the sun are destructive to many forms of bactetia, in some cases destroying them and in others lessening their influence. Thus the importance of well-lighted stables is evident. The dark and sunless building will be a favorable breeding place for bacteria, and the structure which admits the greatest amount of sunlight will be the least favorable for their development. Again, heat will destroy the bacteria of disease. By this is not meant the ordinary heat of the sun but heat as developed in boiling water or in flame. It is upon this principle that the surgeon before operating renders his instruments free from the possible presence of bacteria by boiling, and it is heat which renders a jet of live steam destructive to bacteria, while the application of heat in the form of steam or flame is seldom possible. The result is that in the practical work of disinfection we are dependent upon certain drugs, which have power to destroy the organisms of disease.

Such drugs are known as disinfectants, and, fortunately, we have a number that possess the power of destroying bacteria. It is not the purpose to consider further the relative values of these drugs, neither will it be necessary to discuss the exact manner in which they act. It is sufficient to know that they possess the power of destroying bacterial life with the same certainty that poisonous drugs destroy animal life. They have only to be brought in contact with the bacteria in order to destroy them. As disinfecting drugs vary more or less inp otency and in adaptability to general use, possessing certain advantages as well as disadvantages, it may be well to describe a few of the commoner forms.

Bichloride of Mercury

Bichloride of mercury, also known as corrosive sublimate and mercuric chloride, is used in solution in water, commonly in a strength of 1 to 1,000, though solutions of double strength may be employed. Although possessing great germicidal power, it has the disadvantages of being a violent poison, of corroding metals, and of uniting with albuminous substances, such as excreta, blood etc., and thus forming inert compounds. Unlike the coal-tar products, it leaves no odor in the stable, which is an advantage in connection with the production of milk. On the other hand, care must be used in the handling of a solution of this drug, and feed boxes should be washed with clear water before animals are again permitted access to them.

Chloride of Lime

Cholride of lime (sometimes termed cholrinated lime) is a well known disinfectant, although its value is doubtless greatly over-rateed. This may be due in part to the fact that it is a powerful deodorant—such drugs on account of their pungent odor being popularly belived to have great disinfecting power. Being of uncertain strength and somewhat destructive to metals, and having a permeating odor especially objectionable in a stable where milk is produced, chloride of lime cannot be classed as the most desirable of disinfectants. For general disinfecting purposes it may be mixed with water in the proportion of 6 ounces to the gallon.

Formaldeyhyde

An aqueous solution containing approximately 40 per cent. of formaldehyde and known as formalin has of recent years become a more eor less popular disinfectant.

Formaldehyde gas is in most cases impracticable for stable disinfection. Case formalin is mixed with water and in the proportion of 6ounces to the gallon; the resulting solution is applied directly to surafces of substances which are to be disinfected.

Formaldehyde gas is in most cases. Where, however, the builing can be made almost airtight, and the animals removed, it will be found very servicable, as it penetrates every crevice.

Several methods are in vogue for disinfectinb with formaldehyde gas. Probably one of the most simple and practical methods of liberating such gas is by means of the chemical reaction which takes place when formalin is poured upon permanganate of potassium. Fo reach 1,000 cubic feet of air space 16 2/3 ounces of crystalized of powdered permanganate of pottassium is placed in a wide surfaced pan; ;;20 ounces of formalin is then poured upon it, and the room immediately closed for a period of 12 hours or longer, This method is efficient only when it is possible to seal tightly the rooms or compartments to be disinfected and when their temperature is not below 50 degrees F.

Carbolic Acid

Carbolic acid in its pure form is at ordinary temperatures, in the shape of long, white crystals. For convenience it is frequently dispensed in liquid form by the addition of 10 per cent. of water. A 5 per cent. solution of carbolic acid is sometimes used as a disinfectant, but carbolic acid has the disadvantage of being expensive and somewhat difficult to dissolve.

Crude Carbolic Acid

This substance should not be confused with pure carbolic acid. It is a product of coal-tar distillation and consists for the most part of practically inert oils and cresylic acid. Its disinfecting power depends upon the amount of cresylic acid which it contains, as well as the relative percentage hydrocarbon oils. Owing to its uncertain composition, crude carbolic acid cannot be classed as one of the most desirable disinfectants.

Some General Information on Lime and Its Uses and Functions in Soils

Lime was used more than three thousand years ago in parts of Europe to improve soils. In some parts of Canada and the eastern United States liming has been practiced since the earlier stages of the agricultural development and its use has graudally spread until it is added to the soil to a greater or less extent as far westward as the regions of lighter preciptation. Moreover, its need is quite generally recognized in several of the older settled regions of the west. In reality all lands in the humid regions will sooner or later become deficient in lime since it is constantly removed from the soil by water that pases through it, and by crops taken away.

The amount of lime aplied to the soil in Maritime Canada is steadily increasing from year to year. Investigations by laboratory and field investigators show that the lime content of our soils is deficient, especially in the older fields. Moreover, these studies show that this condition is not confined to any particular class of soil such as sands, loams and clays and mucks, but is more or less common to all, yet the fact should not be overlooked that calcerous formations or those high in lime occur in all classes of soil.

The lime required for maximum returns on the investment varies greatly. Many fields require only small quantities in order to obtain satisfactory results from clover and alfalfa, while medium to very large amounts must be aplied to others to establish these crops and produce suitable yields of many others.

Functions of Lime

The benefits derived from applications of lime are the results of changes induced in the soil that make them more suitable for plant growth. Some of the functions that lime performs are very general in their occurrence, while others are more specific, being confined to a limited number of siils. Inasmuch as several or all of the effects of liming may be operative at the same time it is indeed complex, and therefore variable results from its use are to be expected The various functions that lime may perform in the soil may be conveniently grouped as follows:

1. Modification of soil structure or tilth.
2. Neutralization of acids and other injurious substances.
3. Meeting the silicate requirements.
4. Effect upon the vailibility of minerals.
5. Increase the rate of decay of vegetable matter.
6. Increase the efficiency of fertilizers and manures.
7. Supply needed lime to plants.

Improvement of the Physical Condition of the Soil.—It was formerly assumed that the chief reason for adding lime to the soil was to improve its physical condition or tilth due to its granulating effect upon the fine particles. It is recognized that heavy compacted soils may be somewhat improved in this respect by liming, but this action is less general in occurrence and also less important than others.

Neutralization of Acids and Other Substances Injurious to Plants—Some poorly drained soils as well as some that contain very large quantities of vegetable matter such as peats and mucks carry acids in their soil moisture. These may be injurious to plants, the extent of the inhibitive effect depending upon the amount present. Although adequate drainage may improve many such soils liming is effective inasmuch as lime neutralizes these acids. Moreover, other injurious substances which occur in some soils may be counteracted by adequate applications of lime.

Meeting the Silicate Requirements.—One of the chief effects to be gained from lining the majority of mineral soils is to supply the silicates with lime. It is known that the loss of lime the soil leaves the silicate componds, which compose the major portion of the mineral constituents of the soil, deficient in lime. This condition is detrimental to plants and is popularly spoken of as soil acidity or sourness of soils.

Effect Upon the Availibility of Minerals.—Lime may increase the availability of mineral plant food in some soils. This action of lime has long been held to be a very general and also a very important one, special empahsis having been placed upon the liberation of phosphorus and potash to the plants; but recent investigations indicate that undue emphasis has been placed upon this action, it being negligible with some soils.

Increase the Rate of Decay of Vegetable Matter.—It is well known that the presence of sufficient amounts of lime in the soil results in a more rapid decay of veegetable matter as evidenced by the dark green color of various crops growing on limed land as well as the slightly decayed maturity in some cases. Moreover, the amount of nitrogen in the roots, tops and seed crops may be increased by the addition of lime to the soil. Such changes in the composition of the crops of course show that the available nitrogen in the soil is increased by lime and involve the soil bacteria. It is obvious that the free use of lime on the soil without suitable crop rotation and constant renewal of the vegetable matter content by means of stable manure, crop residues, and catch crops will result disastrously. On the other hand, if these precautions are taken the lime will be instrumental in maintaining the vegetable content due to the increased crop production. In some soils, more frequently in muck than others, the root development of crops is retarded, being confined to the surface layers of soil until lime is added and worked deeply into the soil. Furthermore, the presence of lime in the soil is favorable for the development of bacteria that enter the roots of leguminous crops resulting in the fixation in the plants of nitrogen from the soil atmosphere. Organisms that are able in the absence of legumesfi to remove nitrrogen from the air and make it available to plants are likewise bentfited by lime. It is probable that the amount of nitrogen so made available is small, yet it seems to be worthy of consideration.

Lime Increases the Efficiency of Fertilizers and Manures.—Experience teaches that maximum returns from commercial fertilizers, stable and green manures are not obtained when there exists one or more adverse conditions such as poor drainage, deficiency of water in the soil, poor tilth, or lack of lime. It is unquestionably true that applications of lime to many of our soils long under cultivation as well as some of the newer ones should precede that of fertilizers. If this were done a more economical use of stable and green manures would result.

Some soils do not contain sufficient lime to meet the needs of the crops grown. There is an appreciable amount of evidence, contrary to past asumptions, that the ust of lime on some soils results beneficially because it is needed in plant nutrition, especially is this the case with such crops as clover, or those that remove large quantities from the soil.

Forms of Lime

Lime is placed on the market in three forms, namely, the oxide, the hydrate and the carbonate.

These different forms are often given a variety of names. The oxide is known as quick lime, burnt lime, stone lime, caustic lime, lump line, unslaked lime and building lime. The hydrated lime is also called slaked lime. The carbonate is the form of lime found in ground limestone and marl and aso occurse in air slaked lime.

The term "agricultural lime" may be applied to any of the above forms and refers to lime sold for agricultural purposes but unfortunately not necessarily to a product especialy well adapted for application to the soil.

When high grade limestone is burned in a kiln, 100 pounds of the dry stone gives off approximately 44 pounds of carbon dioxide gas, leaving about 56 pounds of lime oxide or quick lime When 56 pounds of quick lime is moistened it takes up 18 pounds of water and forms 74 pounds of slaked lime or hydrated lime. It is veident then that 56 pounds of quick lime, 74 pounds of hydrated lime and 10 pounds of limestone or lime carbonate have tht same power to satisfy the needs of the soil. However, some of these forme are much more soluble than others and consequently peact with the soil much more quickly and in consequence we do not nse these materials in these proportions in the field.

Sources of Lime

Michigan is fortunate in possessing two inexhaustible sources of lime, her limestone and marl beds. There are numerous limestone quarries in the Maritime Provinces. These quarries produce stone for a great variety of purposes, only a small portion of their output being used in agriculture. Some of the quarries turn out only a coarsely ground rock containing small amounts of fine material, while others furnish a very finely ground high grade rock.

Marl.—The lime is present in the marl as carbonate and hence supplies calcium to the soil in the same form as ground limestone. In addition to lime carbonate some marls contain varying amounts of magnesium carbonate, which also meets the "lime requirement" of the soil The value of marl, then depends on the amount of calcium and magnesium carbonates it contains. A marl carying 90 per cent. or more of these carbonates is considered to be of very high grade.

Occurrence of Marl.—Marl is frequently found underlying areas of muck and peat and also along the shores and in the beds of lakes. In some instances the marl is covered by a few inches of muck while in others it lies beneath several feet of it. The thickness of the beds or deposits is also quite variable. The marl owes its existenct to lime that was washed out of the surrounding soil and deposited inl akes and to the accumulation of shells of lower animals such as the mollusca.

As it occurs in the beds, marl is generally a pasty mass varying in color from light to dark-gray depending upon the impurities present. Upon drying it becomes lighter in color and is easily crumbled, or broken up. If a small amount is placed in half a tumbler of strong vinegar or weakened muriatic acid it will give off bubbles of gas and go into solution. This is one method of identifying marl as well as roughly estimating its purity. Some deposits are filled with small shells which aid in identifying this material.

Wattr Content and Weght of Marl.—When marl is thrown out of the bed and allowed to drain the amount of moisture retained is quite variable and depends somewhat on the amount of impurities. In general tht purer the mare the less water it will hold but sandy marls contain less water than clay marls.

Sugar Factory Lime.—Lime is used by sugar factories to clarify and purify the juice and since impurities cause trouble later in the process of refining a very high grade of lime is used. Milk or lime is added to the vats of juice and then carbon dioxide is run to precipitate the lime as lime carbonate. This is later filtered out and discarded. This material contains a small amount of organic matter from the beet juice but otherwist is a very pure carbonate of lime and is admirable material for applying to the soil. It can generally be purchased at a low cost since it is simply a waste product. It very often contains water and hence it should be bought by the yard rather than by the ton since a cubic yard will contain the same amount of lime carbonate whether the amterial is wet or dry.

Thert is another form of lime which may occasionally be obtained from sugar factories. This is the cleanings from the kiln. Many of the factories prefer to burn their own lime and when the kilns are cleaned a quantity of impure burnt lime or stone is obtained. This material is variable in composition but is mostly quick lime when fresh; after standing a short time itc ontains a large amount of hydrated lime.

Wood Ashes.—In some localities wood ashes may be obtained in sufficient quantities to apply to the soil. Ordinarily wood ashes contain from 20 to 50 per cent. of lime expressed as quick lime but they are usually applied to the soil as a source of potash.

Lime from Acetone and Alkali Works.—There are in the State various acetone and alkali works which turn out lime as a by-product. This material is usually of high grade, its chief drawbacks being a high-water content is exposed to the elements. When it can be obtained near at hand and at a low price it is sometimes more advisable to use such products than to buy the more expensive forms of lime. The cost of transportation and difficulty in distribution must be taken into consideration when figuring the cost.

Change Lime Undergoes when Added to the Soil

When the various forms of lime are added to the soil their composition is altered. The change that is now considered to be most desirable is the union of the lime and siliates to form so-called soil acidity. When hydrated lime is added to the soil some of it goes to form air-slaked lime or the carbanate and some the calcium silicate. Now, the lime or magnesium carbonate thus formed or added to the soil as marl or ground limestone likewise passes to the silicates.

It is now understood that the immediate efficiency of the various forms of lime is dependent upon the rate at which they pass over to the silicate. The hydrate is quite rapid and the carbonates are governed mainly by their mechanical state or the scize of their particles as well as the thoroughness of mixing with the soil mass. Particles of limestone approximating 1/100 of an inch in diameter or so-called 100 mesh lime are about as rapid in correcting soil acidity as the hydrate or 2,000 pounds of it approximates 1,500 pounds of the hydrate in this respect, as exemplified by the following table:

Effect of Forms and Fineness of Lime on the Yields of Rye, Sandy Soil

Treatment	Bus. per acre
Hydrated lime and acid phosphate and nitrate of soda	21.60
Marl and acl dphosphate and nitrate of soda	18.40
Limestone passing 80 mesh screen, and acid phosphate and nitrate of soda	21.28
Limestone, 40-60 mesh, and acid phosphate and nitrate of soda	18.36
Limestone, 10-20 mesh, and acid phosphate and nitrate of soda	14.40
No treatment	12.82

Some limestone deposits ontain calcium or lime carbonate and also magnesium carbonate. If the amount of the latter is rather high they are popularly spoken of as magnesium limestones. The larger particles of magnesium limestones are somewhat slower in their action than the non-magnesium limestones as illustrated by results given in the following table In these studies equal quantities of a given soil were treated with the same amount of magnesian and non-magnesian limestones, the particles of which ranged in size from coarse to very fine. After a period of three years the comparative rate of change, or the efficiency of these in meeting the soil's requirements was ascertained by chemical means. According to these results if the particles are very fine the difference in the rate of transformation is negligible.

Comparative Rate of Transformation of Limestones in the Soil

Per. cent total of carbonates not recovered after three years:

	Non-magnesium Limestone	magnesium Limestone
100 mesh limestone	92.4	91.2
60 mesh limestone	81.5	72.2
20 mesh limestone	46.7	34.9
8 mesh limestone	14.9	5.97

If the lime is not mixed with the soil mass, of crouse, its efficiency is somewhat impaired. Inasmuch as the individual particles of marl are very minute its immediate effectiveness is governed largely by the condition in which it goes into the soil. If lumpy, naturally larger quantities are required to bring about a given result than if it is more or less disintegrated. As it usually goes on the land, about 2½ to 3 cubic yards of 95% marl are required to equal 1,500 pounds of the hydrate and 2,000 pounds of the powdered limestone respectively. This ration decreases the second year inasmuch as the lumps are broken down by freezing and changes in the water content.

Crops Benefited by Lime

The response of our cultivated plants to lime is variable some being more tolerant of a deficiency in the soil than others. Reports on record show that some crops will thrive on a given soil without appication of lime that they are practicaly barren of plant growth. Thus, in discussing the response of different crops to lime it is essential that the condition of the soil with respect to this substance be considered. Some of the field crops that are known to respond to lime are as follows:

Legumes.—Alfalfa, sweet clover, crimson clover, mammoth clover, June clover, alsike clover, soy beans, cow peas, beans, vetch.

Non-legumes.—Corn, oats, wheat, barley ,rye, timothy, buckwheat, sorghum, beets, potatoes, carrots, turnips, cucumbers, cantaloupes, pumpkin, tobacco, cabbage.

Where soils are low in lime the following vegetables are known to respond to its use:- Pepper, parsnips, salsify, squash, spinach, rd beet, celery, cauliflower, lettuce and onion. Many plants grown for their blossoms also respond to lime.

Some results from the use of Lime

Lime may be utilized with ample margin of profit on so-called sour soils. Experiment station workes in man states by means of well-planned and carefully conducted field trials have shown conclusively that the use of lime on such soills is sound practice. For example, Thorne and coworkers of the Ohio Agricultural Experiment Station have made many valuable contributions to our knowledge of the lime relationship of soils and crops.

Wiancko and others, of the Indiana Expeirment Station report that three-fourths of the soils in the State are in need of lime. Where ground limestone has been used on the experimental farms it has returned safe margins of profit.

The results of Illinois experiments, on deficient in lime, conducted by Hopkins and associates, show very strikingly that many soils must be liberally treated with lime before they can be permanently improved. Hopkins, (1912) in commenting upon the results of some 145 tests in six counties, states that the value of the increase has been about four times the cost of the regular application of two tons of limestone per acre every four years.

Whitson and associates of the University Wisconsin, by means of many field experiments as well as laboratory investigations report that soils deficient in lime are quite common in Wisconsin and strongly recommend its use on such for their improvement.

Several experiment stations more remote rom Michigan have made contributions to this subject, notably Delaware, Maryland, New Jersey, Rhode slandI, Massachusetts, Pennsylvania, Tennessee and Missouri.

Reports from several county agricultural agents and many farmers in different sections of Michigan, as well as results obtained from recently inaugurated field tests indicate that the use of lime on the majority of our soils is porfitable.

The Nova Scotia Agricultural College Farm, Truro, and the Kentville Experimental Station have proven the value of ground limestone conclusively.

Liming where needed increases the efficiency of fertilizers and stable manure. Many are the reports to the effect that commercial forms of plant food are unsatisfactory without lime. Some of our recently inaugurated field tests also show that lime may greatly increase the value of other treatments, especially manure and phosphates when they are added singly or together to the soil. These results are in accord with those obtained from long continued trials in other states.

How to Determine if a Soil Needs Lime

There isa general impression that a sample of soil may be taken into the laboratory and the exact amount of lime needed to correct its acidity determined. tI is true that a number of methods have been outlined and extensively employed for this purpose and have doubtless yielded much valuable information. But as yet no method has been devised to use in the field. The results obtained for a given soil by different methods are quite variable and in consequence the lime requirement of the soil will depend somewhat on the analytical method employed.

There are, however, methods of determining whether or not a soil is in need of lime but which make no attempt to determine the exact amount that should be applied.

Perhaps the simplest of thes methods is the litmus paper test. To make this test the soil is moistened with rainwater, and made into a ball. This is broken open and a strip of blue litmus paper inserted into the opening and the soil pressed firmly together around the paper. In about five minutes the paper is removed and examined. If the color is pink the soil ic considered to be in need of lime. In making this test great care must be exercised to obtain a good grade of litmus paper. That obtained from the drug store is often not sufficiently sensitive to give satisfactory results. The paper should not be handled when the fingers are moist with perspiration as this will redden it. Only soft water should be used to moisten the soil.

Treating the soil with muratic acid and noting in bubbling occurs is recommended as a test for an excess of lime but not necessarily a deficiency of lime. No gas may be given off from a soil and yet the growth of crops on the soil may not be increased for several years by the use of lime.

The nature of the growth of plants on a soil is a good indication of its need of lime. Failure or poor growth of clover, alfalfa and sweet clover is very often due to lack of lime. A medium stand of these crops in many cases would have been much improved had lime been applied while preparin gthe ground before the seeding. Some plants such as sorrel are able to grow in soils deficient in lime, and hence subsist where more sensitive ones fail. For this reason the presence of much sorrel is considered an indication of a sour soil.

As pointed out on another page of this bulletin most farm crops are favored by the presence of an abundance of lime in the soils, the effect being especially noticable on alfalfa and sweet clover. Consequently the most satisfactory method of determining the lime needs is to apply some form of lime in dieffrent amounts and carefully note the results obtained. If ground limestone is used the trial applications should vary in amount from one to three or four tons per acre. If the hydrate is employed strips of land should receive amouns ranging from one-fourth to one ton per acre.

How to Apply Lime.

Lime to be most effective must be thoroughly worked into the soil. A thorough incorporation with the soil mass results in the root system of the crops grown coming in contact with larger areas of limed soil. Powdered limestone, marl or hydrated lime should not be applied to wet soils, since the particles form small groups thus markedly slowing up their actions Usually best results are obtained when lime is applied to the soil previous to forming the seed bed.

Machines may be employed for spreading lime. One type is attached to the wagon which carries the lime while the other runs on its own wheels as a separate machine. The latter is in most favor because it can be operated by one man and with less horse-power than is required to draw the farmer and the loaded wagon.

This type of machine may be produced on the market or may be made by a blacksmith and carpenter. A complete description of the plans for making a spreader for ground limestone is presented in Illinois Agricultural Experiment Station Circular 110.

Although ground limestone and hydrated lime may be distributed from the wagon or heaps in the field by means of a shovel, it is usually advisable to employ a machine since its use results in a more uniform distribution when somewhat smaller applications are required.

If the caustic or stone lime is used it is generally advisable to place it in small heaps about the field and cover these with moist earth until slacked and then distributed by means of a shovel. If the lime is not too lumpy it may be distributed without this treatment.

Marl may be applied to the soil with a shovel, a manure spreader or if dry and sufficiently pulverized with a lime spreader. In the use of the manure spreader precaution should be taken to prevent overloading. Some apply marl and manure to the soil at the same operation where the heap of marl is accessible, thus saving an appreciable amount of labor.

Other methods of making more efficient use of labor may be employed. The limestone should be hauled at once thus releasing the car and avoiding demurrage. Arrangements should also be made to spread the lime as it comes from the car thus saving the labor of a second handling. This can often be accomplished cooperatively, that is if neighbors order lime and assist each other in hauling and spreading t.

Where the lime is hauled two miles or less two men, a driver and two teams with three wagons and one lime spreader can take 20 to 30 tons from the car and spread it in two days. One man is kept in the car loading the lime into a wagon. The driver with one team hauls the loaded wagon to the field, leaves it, and takes an empty wagon back to the car and returns with another load. The other man remains in the field and spreads the lime. If the field is large the load may be hauled to the middle line of the field and the distributor filled at this point. Other labor saving plans that are suitable to local conditions doubtless can be worked out.

Dry lime should not become moist before its distribution. It is frequently impracticable to distrbute lime when it is removed from the car thus necessitating its storage. Under such conditions it is advisable to cover it in some manner inasmuch as less labor is required to distribute it in the dry than in the wet condition, when it readily passes through the distributor and in addition the finer grades do not become lumpy.

If bags of lime are stored or piled in the field much labor may be saved by properly arranging the bags in the heaps. If the bags are stacked so that a maximum number may be taken fro ma higher plane and placed upon an adjacent lower plane an appreciable amount of labor may be saved in handling. This may be accomplished by erecting one heap to a convenient height, the thickness being the length of a sack. Joints should be formed at the ends in order to hold the bags in place. A second heap is built parallel and adjacent to the first and to the same height. Then boards may be placed thereon and additions made to the first until a convenient height is again reached. Usually about eight feet is the most practicable height to attain. In removing the bags the reverse order from stacking should be followed.

Usually considerable time and labor is wasted when the lime is taken from the bag and placed in the lime spreader. A convenient scheme is to obtain a corn husking hook that can be fastened on the right hand; the bag is placed on the screen of the spreader on edge. By means of the hook an opening is made along the flat side and near the center, perpendicular to this slit and again near the center of the flat side of the bag another opening is made. The lime may readily be removed by turning the split side of the bag downward upon the screen.

When to Apply Lime.

Since legumes are on the whole more sensitive to a lack of lime in the soil than other crops it is generally considered best to apply lime preceding these crops. When clover or alfalfa is to be seeded in wheat or rye the lime should be spread after plowing and worked into the soil when the seed bed is prepared. If the seeding is to be made with oats or barley the lime may be applied in the spring and worked into the soil. When alfalfa or sweet clover s seeded without a nurse crop the lime should be applied as soon as the ground is broken up so that it may become thoroughly worked into the soil by seeding time.

When vetch is seeded with rye the lime should be spread immediately after plowing. In case the land is not plowed for any of the above crops but is prepared with a disk or springtooth harrow, the lime should be applied before the soil is worked.

THE MARITIME FARMER

And Co-operative Dairyman
Registered Trade Mark
Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definite order for discontinuance is given,

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsible advertisers. To take advantage of this guarantee, written complaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said:—"I saw" your adv. in the MARITIME FARMER.

RATES FOR CASUAL ADVERTISEMENTS.

Contract rates on application.

Address letters and make all checks, money orders, postal notes, etc., payable to

THE MARITIME PUBLISHING CO. or
R. D. Robinson Publishing Co., Limited
Sussex, N. B.

NOTICE TO ADVERTISERS.—Changes of ads. should reach this office one week before date of issue, in order to insure insertion.

RECEIPTS FOR FARMER SUBSCRIPTIONS

The Maritime Farmer, instead of giving you one receipt in the year for a paid subscription, sends you 24, or one every two weeks. You will find it on the GREEN COLORED LABEL on which your address appears. The date printed thereon is that on which your subscription terminates. If on payment of your subscription the date is not changed within two weeks, please notify us. No other receipt will be sent.

DATES OF ISSUE.

June	**10-24**
July	8—22
August	5—26
September (Exhibition Reports)	9—30
October	14—28
November	11—25
December (Xmas)	9—23

MOTTLED BUTTER

Mottled butter is frequently found on the market at this time of year, and, even though it may be of very good flavor, it is strongly discriminated against by the purchaser. As this defect is one of workmanship, it can be overcome by the application of proper methods on the part of the buttermaker, because mottles are caused primarily by an uneven distribution of salt in the butter. This may be produced by insufficient working of the butter, or by churning, washing, and working it at a very low temperature, or by washing or working it at a temperature several degrees higher or lower than the churning temperature .

When the quantity of butter made in one churning is much less tha nusual it is necessary to work it a greater number of revolutions of the churn than usuol in order to produce the same results on the butter. Extremely low temperatues of churning, washing, and working should be avoided, because they produce so firm butter that it is only with great difficulty that the salt can be worked uniformly into it. High temperatures of churning, washing, and working must also be avoided to prevent an abnormal loss of fat in the buttermilk and also the making of a greasy leaky butter.

Great variation in temperature during the manufacturing process should alwals be avoided. Under normal conditions the temperature of the wash water should be the same as, or within 2 degrees of that of the buttermilk.

FARMERS' CLUBS DEVELOP PUBLIC LEADERS

The attendance upon fairs, stock shows, agricultural conventions, granges and farm clubs constitutes a training school for public usefulness in large affairs that perhaps is not esetimated at its full value. Especially is this true in connection with an objection urged against farming as a business by those who say that its isolation removes one from the larger activities which engage progressive pepple, and that farmers have "no chance." Opportunities in the country are regarded by superficial critics as so narrow that however great ones' ability no entrance can be found into avenues of wide influence and positions of public trust.

For those who think in this groove it may be of interest to consider a certain farmers' club, with a membership of twelve families, founded almost thitry years ago. This year one of its members is president of the state board of agriculture; another member is president of the state horticultural society, while a third is the presiding officer in the upper branch of the state legislative assembly. Shall the scoffer say that this is "an interesting coincidence" or a curious "accident," or rother should the fact of three members in state offices be ascribed to the large opportunity for wide thinking and better training in getting on with people which resuls from a long-continued and organized association together in a live farmers' club?

For the onlooker, attending conventions becomes an absorbing pastime when it is not something more serious; a keen relish is found in observing the evolution of the leader, and whether the meeting is considering animal production, taxation, or a local celebration, the chances always are in favor of the man who can speak with some degree of clearness, and in a manner that combines courtesy with confidence in his own viewpoint.

The most plausible explanation of the vitality and formative influence of the farmers' club, to which referensce is made, rests upon the fact that the service and interest of the entire family have been enlited through the plan of limitel membership, which puts upon each family once during the year the duties of host, and preserves the feature of meeting in homes and thereby secures a personal and family loyalty and an individual responsibility thta are lost whenever an organized group grows to require a public hall.

A club which includes the family represents a foundation as broad as life, and suggests topics of conversation at home to bring out every phase of the art, the science and philosophy of a business that uniquely combines living and making a living. So it is that the club "maketh a full mna," one fitted for leadership. The measure of usefulness, however, is not in election to public office but rather in the quality of leadership in local enterprises that interpret the meaning of country life.

DON'T BE A "MOSSBACK"

The world was never less friendly to the "mossback" than it will be in the days to come. The man whose habits of thougth are set and whose minds is closed to the changes about him, will have a difficult time. He will be a dragchain on a world that is moving at a rapid pace. And the world will not cease to move.

Unfortunately there are mossobcks in every realm of life, business affairs not excluded. They are the persons who become fixed in their way of thinking once for all, like concrete poured into a mould; and they never change thereofter. The world advances ,but they stand pat. They are the sworn foes of any ideas that are new. Failing to comprehend a new idea, they usually take the alternative of fighting it. It is a simple maxim that in a world forever changing, it is necessary to adapt one's thought from day to day. Yet this is the fundamental truth which your mossback always fails to grasp. He relies on the "tried and true" of yesterday and never measures up to the "new" of today.

Don't be a mossback.

Arthur Brisbane once said that a man's mind ceases to grow the moment it becomes incapable of digesting information, just as his body loses its vitality when it can no longer assimilate food. The comparison is a good one to contemplate, for no greater misfortune can befall a man in the world of active affairs, be he twenty-five, fifty or a hndred, than to lose his powers of mental digestion.

We stand at the portals of a new era. The diplomats of the nations are handling matters without precedent. They cannot follow beaten paths, but must blaze new trails.

Business must do the same.

There is an opportunity as never before for the man who is alert and progressive, who can grasp a new idea, digest it, assimilate it and translate it into action appropriate to the day. No less than the problem of making new nations, will be the problems of merchandising in a world that is thrill with life born of a great struggle, among people that have been bestirred by wonderful accomplishments.

Business as well as statesmanship will have to give an account of its stewardship. It must be efficient; it must be up-to-date; it must be wide awake. There will be no room for the moss-back, the standpatter, the rock-ribbed bigot, the impeder of progress. We must keep our fingers on the pulse of the times, and meet out obligations and opportunities by methods atune with the moment.

The open mind will be your best asset in meeting the new conditions. If you are eager in your pursuit of information, if you are hospitable to other men's ideas, if your assimilation is good, and if you can turn thought into action, your chances for personal success in the new and unusual year which we are entering, are all that you could possibly desire.

* * *

"The co-operative movement cannot cease to be missionary or its career is ended. It cannot measure its results simply by consideration of material benefit to those concerned; it should create a higher view of the proper conditions of industry and should inculcate a preference for goods which are produced under these conditions. It should never cease to pursue and emphasize the great moral considerations on which all our dealings should be based. Material interests do not function property unless they bring with them that increased sense of duty which must ever accompany a large sense of comradeship. In proportion as we know ourselves to be one of many we lose our selfish individuality in a common life, animated by a common purpose."—Dr. Creighton, late Bishop of London.

* * *

When buying your first purebred cow, buy a good one. You need not necessarily pay a high price, but get a cow which gives evidence of being a producer.

* * *

There is no better place to live and grow and win the best things of life than on the farm and the boy who aspires to a place and position in the outside world need not feel that he is handicapped because he was born and brought up on a farm.

* * *

The modern farmer should take his place as a leader in all things. He should be alive to all that goes on about him that he can use to advantage. The farm should be as well planned and as carefully managed as any other business.

Gleanings From the N.S. Department of Agriculture

REPORT OF THE N. S. DEPARTMENT FOR 1918.

The Report of the Secretary for Agriculture covering the main activities of the Department during 1918 has been issued and is now to be had for the asking. These reports are always repltee with interesting and valuable information and this one is no exception. Perhaps there is more than usual in the way of experimental work in this year's. Not experimental work of the obscure type which is mainly of interest to theoretic science, but the most practical type, dealing with the everyday questions of the wide-awake, practical farmer. By way of introducing some of this matter to Maritime Farmer readers and stimulating a desire to have the Report in their own hands, your correspondent in this issue will summarize a few of the matters discussed.

AN EXPERIMENT IN PASTURAGE

For several years the College staff has been setting forth as strongly as possible the desirability of improving the pastures of the Maritime Provinces. On pp 37-39 of this year's Report Prof. J. M. Trueman outlines a thorough test carried out on the College farm during last summer. The outline is lucid, and constitutes a fine argument for the improvement of pastures. The main points made can be stated in a paragraph, although the full details would add much to the story.

In former reports it was shown that after paying interest on investment, cost of fencing and fertilizer, gains on cattle were made at a risk of somewhat less than 5c per lb., whereas stable gains in the same years would cost 15c or over.

In this year's Report Prof. Trueman includes in the costs a very considerable amount of plowing, seeding and manuring done for the purpose of getting part of the pasture in good sod. Even with these extra high charges the cost of gains made per lb. reaches only 5.4c, on pasture whereas stable gains have increased to 20c or more.

It might be said in addition, although it is not included in this particular experiment, that the same principle holds good on the milk production end of the cattle business. Under present conditions Creameries and Cheese factories pay almost as much for butter fat, in summer as in winter. With winter feed very high it needs no elaborate argument to show that it pays the farmer to specialize on summer production. Both Beef and Dairy interests, then, are clamouring for better pasturage. For full details on the test see the 1918 Report, which may be had free. Drop a post card to the Secretary for Agriculture, Truro, N. S.

ROYAL BLOOD AT THE COLLEGE FARM

The Queen of Canadian cows is "Jemima Johanna of Riverside". Her photograph occupies the full front page of the "Farm and Dairy" for April, from which paper we quote the following:—"Jemima" is the new champion in Canadian Record of Performance, having just completed her year with over 30,000 lbs. of milk and 1250 lbs. of butter. She displaces the Jersey, Sunbeam of Edgeley, that has held the premier position in butter production for several years with 926 lbs. of butter fat, equivalent to 1157.5 lbs. of 80 per cent butter. In milk Jemima replaces the Alberta cow, Queen Posch Wayne. She has some wonderful records made eight months after calving, producing in seven days 25.23 lbs. of butter; 30 days, 101 lbs. butter; 60 days, 199 lbs. butter."

It is a striking testimony to the competence of the College management in their avowed policy of keeping the very best available foundation stock, that they have on the farm at Truro the Dam, "Jemima Wayne Sarcastic", and three uterine sisters of this new champion cow. These are high up in the aristocracy of Dairy cows not only in Canada, but in the world. The cows which have made greater records than the above are very few, if, indeed, any have done so under similar conditions.

NIT. OF SODA ON RUN OUT FIELDS

In the Annual Report for 1918 Prof. Trueman on pages 28-33 sets down in tabular form the results of an experiment in fertilizing a field of oats on a badly run out and badly drained farm. Unfortunately for the best results the crop was not harvested until October owing to wet weather. This caused considerable loss, so that all yields are small, but the relative results are well worth noting.

Almost every possible mixture of fertilizer was used in the experiment, the details being fully set forth in the report. The outstanding fact to be noted here, however, is that the use of 100 lbs. of Nitrate of Soda per acre gave an average increase in yield of 11 bushels.

It is worth noting that in this case the Nitrate was applied at the time of seeding, but other experiments have proven that at least equally good results can be obtained when the crop is up several inches. A condition to be carefully observed when applying it to growing crops is that the day and the plants be dry, to guard against burning.

In watching the growth of the grain on the experimental plots during the summer a marked difference was very plainly to be seen between those which had and those which had not received the Nitrate application. The extra vigour, thickness and height of the oats caught the eye at once. The value of the extra grain and straw resulting from the use of $5.50 worth of Nitrate amounted to $12.66. Every practical gardener knows its value on high priced crops, but this experiment demonstrates that it can be profitably used on the grosser products.

During the war and until recently nitrates were very difficult to obtain. Large quantities are now being released, and the Imperial Munitions Board, with headquarters at 56 Church St., Toronto, are advertising heavy supplies for sale.

DR. MELVILLE CUMMING

In conferring the degree of L.L.D. on Principal Cumming at its recent Convocation, Dalhousie University paid tribute not only to his personal worth, but also to the vital function of Agricultural Education which has claimed so large a share of his time and energy. It is given to few men to serve their generation in such a variety of interests and activities as Dr. Cumming is serving his. He is, above all else, however, the champion of the rural community and the advocate of its well being. Amid the multitudinous duties of his dual position as Secretary for Agriculture and Principal of the College, and all the demands which evolve out of a thorough experience and a reputation for good judgment, Dr. Cumming finds time for that careful analysis which alone can yield reliable data in dealnig with so complex a matter as the modern rural problem. The College at Truro, in itself and in its politics, is performing an immesurable service to the country by fostering in its students a high appreciation of Agricultural Education, and by fostering in its students a high appreciation of all round citizenship. Congratulations and best wishes to Dr. Mellville Cumming.

GREEN FEED FOR CATTLE

The foresighted farmers needs no urging to take measures now against the dry and failing pastures of the average August and September. Now is the time, and not a moment too soon, to get ready and sow a reasonable area of some green supplement to feed in those months and to store as silage,

One of the very best possible crops for this purpose is the oats, peas and vetches (O.P.V.) mixture. It is a hardy and sure crop, yielding on good land about 10 tons to the acre, and on analysis showing up finely in food qualities. Moreover, it is a crop which requires no cultivation during the season of growth, and no curing for the silo. It must be remembered however, that this is an unprofitable crop on poor land.

The O.P.V. mixture is sown in the following proportions:—2½ bus. oats, ¾ bus. field peas and 1/3 bus. common vetch, making a mixture of a little over three bushels, which is about the right amount to sow to the acre. It should be sown as early as possible.

The next crop for this purpose is fodder corn. This is not so reliable in some parts of the Province, but good results have been obtained in a succession of years at the College Farm, Truro. The yield runs up to an average of about 11 tons t othe acre, cultivation during the summer months being, of course, necessary. It is sown about the first of June. The varieties which have proven best in this vicinit yare Longfellow, White Cap, Yellow Dent, Golden Glow and Wisconsin No. 7.

INSECT PESTS

An incalculable loss is suffered year by year through the ravages of insect pests. Many of these are now well under control. Their life history is known and they are attacked at the point in their career at which they are most susceptible to poisons or other destroying agents. New forms are continually appearing, however, and there is no end in to the fight.

This season the Entomological Division of the Department of Agriculture at Truro is sepcializing on three types which seem to be on the increase, and about whch little is definitely known. These are the Carrot rust fly, the Pea moth and the Onion maggot. A considerable plot of ground has been set aside for experimental purposes and Prof. W. H. Brittain, with his asistants, have some twenty odd poison mixtures ready to test out during the season. Farmers and gardeners over the country will watch with eager interest for announcements of results.

A word may be added about an old foe, the Cabbage maggot. Effective preventive remedies have recently been discovered, but these will not be available to the public in any quantity this seasoi, so the best preventative measure within the reach of all is the tar paper disc. These are now manufactured for the purpose, ready to put on. Failing to obtain them, however, but a sufficient amount of One Ply Tar Felt. Cut in squares or circular form with a slit to slip over the stem of the plant. Where the plant rests at the center cut in criss cross fashion so that the plant will not be injured, but be careful that the fit is good and the disc lies level, for a very small opening down by the stalk will admit the fly that lays the fatal egg. The habit of the fly is all that need be remembered in order to frustrate its design. The fly alights on the stalk. head up, then thrusts her abdomen down along the stem and deposits her eg gbelow the surface of the ground. Prevent this operation and you will save your cabbage.

DAIRYING IN N. S. SCHOOLS

A few years ago while carrying on Record Center work in the western parts of Pictou County, Mr. H. R. Brown, of the Federal Department, was impressed with the idea that Dairying to be successful must be taught in the schools. He aroused the interest of a number of teachers, and outlined some lessons on the subject which were put on by those teachers. At the end of the term prizes were offered for the best essay on Dairy work. A two years' trial of this method demonstrated its usefulness, and Mr. Brown prepared a Bulletin—"Short Lessons on Dairying," which was published in 1918 at the expense of the Nova Scotia Department of Agriculture, Dairy Division. Professor DeWolfe, Director of Rural Science, realizing the importance and adaptability of this bulletin, brought it to the attention of fthe Rural Science teachers. These teachers, of whom there are eight covering the province, took special lessons in Dairying at the Agricultural College, and the Dairy Division supplied each one with a milk testing outfit in a suitable carrying case. As they go from place to place they give demonstrations and set such practical problems as are contained in the bulletin all with the object of acquainting the scholars with at least the rudiments of scientific dairying.

Many Agricultural Eocieties, progressive farmers and business men, as well as Creamery corporations, seeing the value of this work, are contributing prizes for competition in each county or district, to be awarded to the writer of the best essay on the subject. To crown it all the Dairymen's Association is this year offering a grand champion prize of $20.00 for the best essay in the whole province.

THE POULTRY FLOCK

In the keen competition of the modern world of commerce and mnufacture the difference between success and failure is often simply whether or not there are loose ends and overlooked details of loss. The firm which succeeds in stopping leaks and utilizing by-products is pretty certainly on the highroad to profits. Possibly in lesser measure, but with no less certainty profit or loss in farming is determined. We have a known numbers of farmers whose margin of gain, which in time made them fore handed and independent, came from the poultry flock, the strawberry patch and the early vegetable field.

Among these smaller side lines in farming probably the products of the poultry pen have shown a greater advance than those of any other. The old days of abundant cheap feeding material, of course, are gone, but a fair-sized flock with good management may still send a boy to College in a very few years.

Records of flocks in both town and country localities are summarized in this year's report of the Secretary for Agriculture. The general conclusion from all taken together is that a well managed flock will turn in a net profit of $2.00 per fowl. To do this they need no heavy expenditure in the way of building or equipment, a simple, sanitary house kept clean and dry is all they ask in the way of shelter. There are certain well defined articles of diet which they must have to do their best. There must be regularity in attendance, and opportunity for exercise. They attend to the rest. There is no better training in habits of industry and business efficiency for the juniors of the family than the management of a flock of hens. By the way, this 1918 Report of the Secretary for Agriculture is a gold mine of information on this and many other farm topics. Why not get a copy? They are to be had for the asking. Drop a card to the College at Truro, or to any member of the local Legislature.

WINTER INJURY TO FRUIT TREES

(Address by Prof. Crow, of O.A.C., at Ontario Fruit Growers' Convention)

Winter Injury to Fruit Trees is not an unusual occurence in Ontario and other countries having low winter temperatures. Fortunately for the fruit growers the losses due to low temperatures are usually not heavy. The winter of 1917-18, however, proved an exception, and great losses to our fruit plantations occurred in every part of Ontario. It is quite safe to say that thousands of trees were killed outright and hundreds of thousands were damaged more or less. The full extent will not be known until after next summer, as many which were not killed outright last winter will likely die before the close of the next season.

Nearly all kinds of fruit trees were injured, the extent of the injury varying with the locality, the kinds and varieties grown. From Toronto eastward to Belleville the loss was heavy —in some cases as many as 50 percent. of the trees in some apple orchards being killed. In other cases the loss wis lighter. As a general statement one could not say that the loss in apple orchards in this section averaged over 20 per cent. From Torronto westward and southward the damage in apple orchards was not so heavy as in the east, but nevertheless it was heavy enough to cause appreciable loss to growers. In the warmer parts of the province the chief loss to apples occurred in young orchards which had been cultivated late in the season. In the northern apple sections, e. g., Simcoe County, considerable loss was experienced, excepting in orchards which were very well protected.

European and Japanese plum trees were quite badly killed in the Ottawa district. The American varieties, however, came through in good condition. In the Niagara district plums were not badly damaged, although in other section some loss occurred.

The crop of sweet cheries was light in 1918, and this may have been due to the killing of fruit buds. Sour cherries were also damaged more or less; the degree depending upon the latitude. In the colder sections of the province sour cherries were killed outright. At Craighurst, in Simcoe County, Mr. Caston reports that even the hardier Russian varieties were killed. In the warmer section less injury was noticed. As with sweet cherries the crop was light ,the reason for which has been previously noted.

Peach trees in the Niagara district and other peach growing sections were more or less injured. In some sections the loss was quite heavy in young peach orchards—one grower in Essex County losing twenty acres of young trees. In the peach growing area in Lambton the damage was quite heavy, many trees being killed outright and the remainder were badly killed back.

Pears where grown were injured considerably in the colder sections, and even in the pear growing districts some damage occurred, especially on varieties which had been top worked on Keiffer stocks.

Forms of Winter Injury

Nearly all the forms of winter injury noted by those who have studied this question, were seen by the writer during the past summer. These vary in degree from complete killing of the tree to bud killing and include root killing, collar rot, bark splitting, sunscald, black-heart, killing of bark on the trunk, crotch injury, killing of bark on large and small limbs, killing of fruit spurs, killing of fruit buds, and killing back of terminal growth.

Root Killing

The roots of young fruit trees are some times killed in winter, while the trunk and branches are uninjured. Trees injured in this manner usually come out in leaf in the spring, but in a short time the leaves wither and die. If the roots are examined the bark wil be found to be dead and brown. Root killing is caused by deep freezing and is induced by the following factors: Tender root stocks used in propagation, absence of snow or other protective coverings, exposure to strong cold winds, late fall plowing and poor soil drainage. This form of winter killing is generally worse on light sandy or gravelly soil, especially on ridges of the same types. Profesor Macoun states that very little root killing has occurred at the Central Experimental Farm since the root of the Siberian crab have been used for yrafting.

Collar or Crown Rot

Collar or crown rot is so called because the bark near the collar or crown appearsto be dead on a small are a of bark or it may extend all the way round the tree and for some distance above the ground. Certain varieties of apples such as the King, Ontario, Pewaukee, Duchess, Gravensteinfi, are susceptible to this form of injury. Cherry and peach trees are also occasionaly affected by this form of winter killing.

Bark Splitting

Barg splitting may be noticed on Sweet Cherry Trees and on some varieties of aples. The bark is often split vertically from the ground up for several inches; in some cases almost up to the limbs. One of several splits may occur and in extreme cases the bark will split away from the trunk laterally as wel as vertically. A few trees were seen on which the bark could b epulled entirely away from the trunk by taking hold of one of the exposed edges. In apples the Stark and Ontario are quite susceptible to this form of injury.

Crotch Injury

Trees affected with crotch injury showed an area of dead bark in the crotch. This might be confined to the crotch or it might extend clear around the base of the limbs, and in some cases also the trunk just below the crotch. Severad trees were observed on which the dead are of bark extended down the trunk in a long V. shape or in an irregular form. The varieties most affected were Young Northern Spy, Cranberry Pippin, Baldwin, Gravenstein and Scarlet Pippin.

Killing of Bark on Trunk

On many trees the bark on the trunk was found to be dead and discolored. The dead are a might be conned to large pafitches or as was frequently noticed nearly all the bark on the trunk above the snow line was dead.

Black-Heart

This is common trouble on young Baldwin trees in many parts of Ontario and is especially prevalent on trees growing in areas exposed to cold winds. .One grower in Norfolk has lost several hundred Baldwins from Black-Heart. Black-Heart may sometimes appear in the nursery but will also attack older and larger trees. It is generally worse in trees exposed to strong cold winds. The injury is thought to be due to freezing of the sap-wood; t;his causing a dark discoloration; hence the name of Black-Heart. The cambium layer, however, is not injured and continued to form new layers of sap-wood. In course of time, if the injury is repeated, the injured sap-wood may decay and this often weakens the trunk or branches to such an extent that they break down or die.

Killing of Bark on Branches

The bark on the larger branches was often to be affected very much the same as that on the trunks.

Killing of Fruit Spurs

The fruit spurs on many apple and some pear trees in the colder sections were frequently killed back to the branch on which they were borne. Some pear trees were observed where the fruit spurs were killed as described and from near the base of the spur strong vigorous shoots had started to grow, when seen in June.

Kililng of Fruit Buds

This form of injury is not uncommon, especially on peaches and cherries. The buds arc killed by extreme cold or through starting into growth in mild weather and being subsequently frozen in cold snaps.

Killing Back

The terminal growths on young and old trees are occasionally killed by severe freezing. Injury of this kind is generally confined to the previous season's growth but during the past winter it often extended into the older wood. Peahces and some varieties of apple trees are quite susceptible to this form of injury.

FACTORS WHICH PRE-DISPOSE FRUIT TREES TO WINTER INJURY

The question may properly be asked, what are the factors which pre-dispose our tree fruits to damage by low temperatures. As is well known, the primary cause of winter killing is very low temperature, but along with this there are several factors which may directly or indirectly increase the degree of injury. These are given herewith.

Cold Resistance of Varieties

It is a well known fact that there is a great difference in the hardiness of varieties, when grown in the same soil and under the same conditions. The past winter has shown more clearly than ever before, that certain varieties are more resistant than others. In Ontario the hardiest varieties are mostly those which originated in Russit, aCnada or the Northern States. The unfortunate thing in connection with those of Russian origin is that while they are every hardy there are really no first-class apples amongst them. The good varieties of Canadian origin, while hardy enough for most winters are not sufficiently hardy to stand exceptional winters such as the past one.

Exposure to Strong Cold Winds

Trees growing on the sites exposed to strong cold winds were invariably injured to a greater extent than those growing in well protected areas. Examples of this were seen in Norfolk, Prince Edward and in York counties.

Late Cultivation

Orchards which were cultivated late in the season were generally more severely injured than other orchards in the same localitiese where cultivation was discontinued early or where but very little cultivation was given. Late cultivation causes the trees to grow late in the season. In such cases the wood does not ripen properly and hence may be injured by very cold weather. Killing back and bark splitting may be induced by late cultivation. I do not wish to depreciate the value of orchard cultivation by any means, as I think that judicious cultivation will produce good results, but I do think, however, a mistake has been made by cultivating too late in the season. Plowing the soil away from the base of the trees late in the fall is not advisable, as it may pre-dispose the trees to collar rot. If fall plowing is done do not plow the soil away close up to the trees. If the orchard is plowed in the fall, plow so that the soil is thrown toward the trees, not away from them.

Poor Soil Drainage

Trees on poorly drained soils were invariably injured more than those on well drained soils. The fact was noticable in all sections but especially so in the peach growing areas.

Lack of Soil Fertility

Bearing trees growing on soils deficient in fertility were more severely injured than those growing on moderately fertile soils. Of course it is possible to make some soils too rich especially in nitrogen, but this seldom occurs. My own observations and the observations of others who have studied winter injury justify me in stating that many of our bearing fruit trees are pre-disposed to winter killing by lack of food.

Heavy Production of Fruit During Preceding Season

Trees which bore a heavy crop of fruit in 1917 were more severely damaged than trees of the same variety or of the same hardiness which bore a light crop or no fruit during 1917. In Prince Edward Co., the writer saw what appeared to be an example of the relationship of heavy fruiting to winter injury. A Pewaukee tree had the unusual habit of producing a crop of fruit on a central leader branch in one year and the next year the lower lateral branches bore fruit. On this tree the central limb bore no fruit in 1917 and in consequence thereof appeared to be quite healthy, while the lower lateral branches which bore a heavy crop in 1917 were nearly all dead. In Northumberland County a Northern Spy orchard, which bore a heavy crop of fruit in 1917, was badly injured during the last winter, while another Northern Spy orchard nearby on practically the same soil escaped almost uninjured, due largely to the fact that but litte fruit was produced in 1917. Prof. Macoun, of the Central Experimental Farm, gives some interesting data on this question. Accurate records kept annually for twenty years show that the heavy bearing trees are much more susceptible to winter killing than those which produce a light yield or no fruit at all.

Insect Pests and Plant Diseases

Insect pests and plant diseases which attack the foilage of fruit trees often weaken the trees considerably by nterfering with the gromth processes, which are necessary for the proper maturity of wood and thus predispose the trees to winter injury.

HOW CAN WE PREVENT A RECURRENCE OF THESE LOSSES

Fruit growers everywhere are asking the question.—What can we do to prevent a recurrence of the losses of the past winter? This problem is not easy to solve as we have no reasonable assurance that similar climatic conditions may not return and cause further losses. Until we can produce by plant breeding and selection, good varieties that are hardier than any we now have, we cannot hope to escape some loss by winter killing. This work is of necessity very slow and cannot be undertaken with the hope of immediate returns by the fruit-grower. Work of this nature is under way at our Provincial Experimental Stations, but in view of the losses which have been sustained during the past ten years and especially during the past winter it should be carried on much more extensively than heretofore. The interest on the capital value of fruit trees destroyed in Canada during last winter would adequately finance an undertaking of this kind. It is quite true that the present generation of fruit growers would not derive much benefit from this work but we should not forget thta we are now reaping the benfit of the labor of horticulturists who have gone before and if we are to do for others as have been done by, we should continue this excellent work and do something for those who come after us.

Good Cultural Practices

The other preventative measures whihc might be employed to advantage are only those which are considered to be the best cultural practices. The value of these cultural practices and principles to be observed in the selection of sites for orchards have been more clearly emphasized by what occurred last winter.

In regard to cultural practices, I would suggest that orchard cultivation be started as early in the spring as the soil can be easily worked. The

Grow Strawberries for Profit

Do you know that one Farmer in New Brunswick sold nearly $5000 worth of berries from five Acres? That another Farmer sold over $8000 worth from a little over ten acres? These results are not exceptional, any good farmer can do as well who will give his attention to the most profitable crop that can be grown in the Maritime Provinces. We can supply Plants for the professional Strawberry Grower, for the man who grows an acre or two as a side line to general farming or for the family garden. Good strong well rooted plants are more than half the battle in successful strawberry culture. Start right. Don't take plants from an old bed or from the side of the rows as a gift. All Farmers know that poor seed means a poor crop. Dunlaps, Warfields and Beder Woods $4.00 a thousand; Sample, Glen Mary and Dr. Burrell, five dollars a thousand.

Hantsport Fruit Basket Co., Ltd.

HANTSPORT, N. S.

time when cultivation should be discontinued will depend upon such factors as latitude, soil and climatic conditions. As a general statement, I would say that cultivation should be discontinued earlier than is the usual custom except in dry seasons and on lighter soils. In such cases it would be wise to cultivate later than on heavier soils or in seasons when rainfall was abundant. For apple orchards the range of dates for stopping cultivation would vary from early June for the north to July 1st in the southern sections. Peach orchards, of course, should be cultivated somewhat later than apple orchards, up to August 1 in most cases.

Use of Cover Crops

Cover crops exert a beneficial influence in checking the late growth, help to ripen the wood, hold the snow and may prevent deep freezing on light soils.

Judicious Use of Manures and Fertilizers

Bearing orchards should be supplied with plant food in sufficient quantities to keep the trees in good thrifty condition but care must be exercised, however, to prevent forcing the growth of trees, as this would pre-dispose the trees to several forms of winter killing.

Soil Drainage

The darinage for soils intended for fruit growing is of the greatest importance as a means of preventing winter killing. Soils which are not naturally well drained should be thoroughly under drained. This will pay handsomely as trees growing on well drained soils will invariably give much better results than those on poorly drained soils.

Thinning of Fruit

In seasons when labor can be obtained at a moderate price it will pay to thin the fruit on heavily laden trees. As previously mentioned heavy bearing is a big factor in predisposing trees to winter killing and it would seem that for this reason alone the practice would be profitable.

Thorough Spraying to Control Insects and Disease

Professor Casear and others have repeatedly pointed out the benefit to be derived from thorough spraying as a means of controlling plant disease and insect pests. The experience of the past winter has shown clearly that thorough spraying is of definite value in preventing winter killing by destroying insects and diseases which by their attacks weaken the trees and thus pre-dispose them to winter killing.

Provision of Shelter Against Strong Cold Wnids

A good wind break, properly located, will undoubtedly lessen the amount of winter killing. This applies espceially to the colder sections of the province, but would apply equally well to any section where the orchard was exposed to high cold winds or was located on exposed sandy or gravely ridges. In some of the warmer areas of the province where natural conditions are most favorable or where land is very expensive it may not be necessary or profitable to plant wind breaks but there are many other places where wind breaks would doubtless be worth while. Wind breaks should not be located too close to the trees as they might cause a dead air space in their immediate vicinity and thus cause the development of fungus diseases, such as apple scab and soot blotch. If set back some distance, say from 150 to 200 feet or more the protection afforded would be quite effective and trouble from diseases would be obviated.

Proper Choice of Site

A site for an orchard should have air drainage as well as soil drainage. An ideal site is on a gentle slope (preferably to the north or north east) where the cold air can flow down to the lower areas. One should not locate an orchard in a hollow where cold air settles, as such a site will favor injury to the trees in winter and to the blossoms during cold spells in the spring.

Hardiness of Varieties

With the exception of most of the crab apples and American plums, very few kinds of fruit or varieties have proven absolutely hardy. At Ottawa some of the hardest Rusian sorts were injured. There is, however, a marked difference in the cold resistance of varieties. I am going to give you a list of the varieties which have proved somewhat cold resistant and also a list of varieties which have been rather seriously injured.

Vaireties Least Affected

1—Hibernal; 2—Duchess; 3—Patten's Greeening; 4—Dudley; 5—McIntosh; 6—Yellow Transparent; 7—Wolf River; 8—Wealthy; 9—Haas; 10—McMahon White; 11—Snow; 12—Alexander; 13—Baxter Golden Russet; 14— Scarlet Pippin; 15—Spy.

Varieties Most Affected

1—Baldwin; 2—Ontario; 3—King; 4—Cranberry Pippin; 5—Wagner; 6—Spittneburg; 7—Gravenstein; 8—Hubbardston; 9—Stark; 10—Pewaukee; 11—Ben Davis; 12—Bottle Greening; 13—R. I. Greening.

How About Your Binder?

EVERY sign points to a prosperous year. For years you have been cheerfully complying with Government request to save materials by repairing your old machines rather than making replacements. Now that the need for this has passed, would it not be real economy to buy new machines and be assured of uninterrupted service at a time when a break-down would mean serious embarrassment and loss.

Deering and McCormick Harvesting Machines

will harvest all your grain crops without waste. Generations of farmers have tested and approved until these machines are spoken of in much the same fashion as an old and trusted servant.

See the local agent early and have your binder delivered in plenty of time to assure the complete harvesting of your crop. Our organization being an essential industry has been speeded to top-notch efficiency. By anticipating your needs and ordering early, you make it easier for us to take back our soldier boys without disturbing our present organization. It will be wise also to make your purchase of binder twine as early as possible.

Service follows Deering and McCormick binders to the grain fields. That this service be full measure, 16 branch houses keep informed of your needs and equipped to supply them. Write now for catalogues and order early.

100 Yards of Ditch in Three Hours

—a better, cleaner and more satisfactory ditch than one dug with pick and shovel, and made in less time and with less labor and less money.

C. X. L. Stumping Powder

dug this ditch—it is digging ditches for hundreds of farmers, who have found the value of C. X. L. on the farm. Whether you want to drain or irrigate—whether your field is upland or swamp—the C. X. L. way is the most practical.

Use C. X. L. for stumping clearing your waste land and planting your fruit trees—it does the work easier, more economically and it helps to produce better and larger crops.

Our book "Farming with Dynamite" tells you how you can use C. X. L. profitably on your farm. Write for your free copy today.

DAIRYING.

SCORING AND GRADING CHEESE

The folowing scale of points for scoring cheese was adopted at the Dominion Dairy Conference:

1. 45—Flavor—acidy; fruity; rancid! tainted; cowy; weedly; bitter; gassy; heated.
2. 25 — Texture — stiff; corky; mealy; weak; lumpy; pasty.
3. 15—Closeness—loose; ragged holes; gas or pin holes; swiss holes.
4. 10—Color—streaky; wavy; mottled; acid cut; high; light.
5. 5—Finish—rough edges; crooked ends; soft rinds; mouldy; dirty box.

Total 100 points

Grades for Cheese

Special Grade.—Score 94 to 100 points. Minimum for flavor 41 points.

First Grade.—Score 92 and under 94 points. Minimum for flavor 39 points.

Second Grade.—Score 87 and under 92 points. Minimum for flavor 39 points.

Off Grades.—Score under 87 points and under 37 points for flavor.

Standards for Grading Cheese

Special Grade

Flavor—Clean, sound and pure.
Texture.—Close, firm and silky.
Color.—Good and uniform.
Finish.—Even in size, smoothly finished, sound and clean surfaces, straight and square.
Boxes.—Strong, clean, well made. If made of wood, ends to be seasoned timber. Close fitting. Weights stenciled or marked with rubber stamps.

First Grade

Flavor.—Not quite clean.
Texture.—Slightly weak or open.
Color.—Uniform.
Finish.—Fairly even in size, well finished, sound surfaces.
Boxes.—Strong, clean, well made. If made of wood, ends to be seasoned timber, close fitting. Weights stencilled or marked with rubber stamp.

Second Grade

Flavor.—"Fruity," not clean, "turnipy" or other objectionable flavor.
Texture.—Weak, open, loose, "acidy," too soft, too dry.
Color.—Uneven, mottled or objectionable shade.
Finish.—Very uneven in size, showing rough corners, black mould, dirty or cracked surfaces, sott rinds.
Boxes.—Too large in diameter; top edge box more than ½ an inch below the top of the cheese. Made of light material. Ends made of improperly seasoned material.

Off Grade

Flavor.—Rancid, badly "off," anything inferior to secnod grade.
Texture.—Very weak, very open, showing pin holes, or porus, very "acidy," very soft or very dry.
Color.—Badly mottled, or very objectianable shade.
Finish.—Anything worse than second grade.
Boxes.—No question of boxes sufficient to make third grade if other qualities are good.

MAN OR MACHINE; WHICH IS AT FAULT?

It is not the most unusual thing in the world to find in the same neighborhood—maybe only two or three lots apart—two farmers who are both owners of milking machines, likely as not of the same make, but who have developed radically different opinions about the merits of their respective investments. One of the men may be using his machine, two, three, or perhaps four, times a day, simply cannot say enough good things about it, and gives the impression that he is just about as well pleased with his bargain as it is possible for a human being to be. On the other hand, a look in his neighbor's barn indicates a different state of affairs; his milking outfit, or what is left of it, is piled up in a heap in an out-of-the-way corner of the milkroom, more or

PAROID
A
NEPONSET ROOF

THE economy of roofing with Paroid is apparent when you consider:—

It can be laid quickly, and at half the cost of new shingles.

When put on, Neponset Paroid forms the ideal roofing—fire, weather and wear-resisting.

Neponset Paroid Roofing lives long, stands up, and pays for itself yearly by giving absolute protection and satisfaction.

Neponset Paroid Roofs have proven their durability and economy for twenty years.

Neponset Paroid Roofing can be applied over old shingles without the added expense of tearing them off.

A full set of the tools required for laying Paroid is shown below.

Roof with Neponset Paroid—it Pays.

Neponset Paroid Roofing is made in three colors: red, green and slate grey.

Sold by Hardware and Lumber Dealers.

less hidden undera heavy coating of dust. The general appearance of the wreckage makes it quite unnecessary to ask any qusetions about what has happened; in fact, it might be a rather risky business to bring the matter up at all. The big question mark is, where in the world does the big difference come in? How is it that one man can purchase a mechanical milker and turn it into a big business asset, while his neighbor promptly throws his machine into the discard? Both men are rated as good farmers, and have both made a go of the dairy business, but when it comes to handling a milking machine—well, the reader knows the story.

The Man or the Machine?

There must be some explanation for this sort of thing, but where? Could the trouble be in the machine? Hardly reosonable to put the blame there, is it, when others have found it a first-class proposition? Evidently the trouble lies with the man—"the man behind the gun" if you like! The milking machine, perhaps more than any other piece of machinery around the farm, pays a high premium for a little bit of care and patience, and levies a correspondingly heavy toll for any sort of neglect. Carelessness in the matter of washing the machine sends the bacteria count of the milk high, and brings a complaint from the cheese factory or creamery. Lack of attention to lubrication and other such details about the engine and pump pave the way for other trouble—poor vacuum and all the rest of it. Running the machine too fast does not give it the proper chance to do good work, the trouble often being that the pulsator is working too fast to allow time enough for the inside rubber tube in the teat cup to collapse and release, the effect being to produce a steady suction instead of the intended pulsating movement.

These are a few of the common troubles which often lead to machines being "blacklisted" by their owners, when the fact of the matter is that the man behind the machine fell down on his job. Don't be in a hurry to condemn your machine until it gets a good, thorough tryout with working condiitions just as near what they should be as can possibly be arranged.

IMPORTANCE OF GOOD VENTILATION

No doubt everyone wil admit that the proper ventilation of stables is of the greatest importance. More mistakes have been made in the attempts to ventilate stables than in almost any other part of their construction. We believe the reason has been that the fundamental fact in the movement of the air, and the cause of currents, has been ignored. Another reason is that it is a vrey difficult matter to ventilate in such a way that the temperature does not become too low for th ecomfort of the stock. If the animals are kept too cold, they will require more feed, if they are expected to produce to their full capacity.

In ventilating a stable, two things are necessary, the first being to get rid of the foul, impure air, the second to get fresh, pure air to take its place. There is a difference of opinion as to how these conditions can best be attained. Some experienced dairymen claim that the foul air, which is always the warmer, must escape at the top of the stable, and the cooler air must enter at the bottom. In order to accomplish this, openings near the ceiling of the stable must be made, these openings to be regulated by slides so that the quantity of air escaping may be controlled, as the weather may happen to require. The foul air flows out of these openings, and a current of pure, fresh air flows in at the openings near the floor, which are regulated the same way as those above.

To spread the flow of air, the openings should not be directly over each other, but should be placed alternately, thus preventing drafts on the cows, and circulating the fresh air equally over the stable.

There are also some experienced dairymen whose ideas of proper ventilation are directly opposite. They advocate that the foul air of the stable is heavy, and tends to sink rather than rise, and that exit ventilators should run from within a foot of the floor to the roof, while the inlet for fresh air should open near the ceiling of the stable, thus allowing the pure air from the outside to permeate the warm air before coming in contact with the animals.

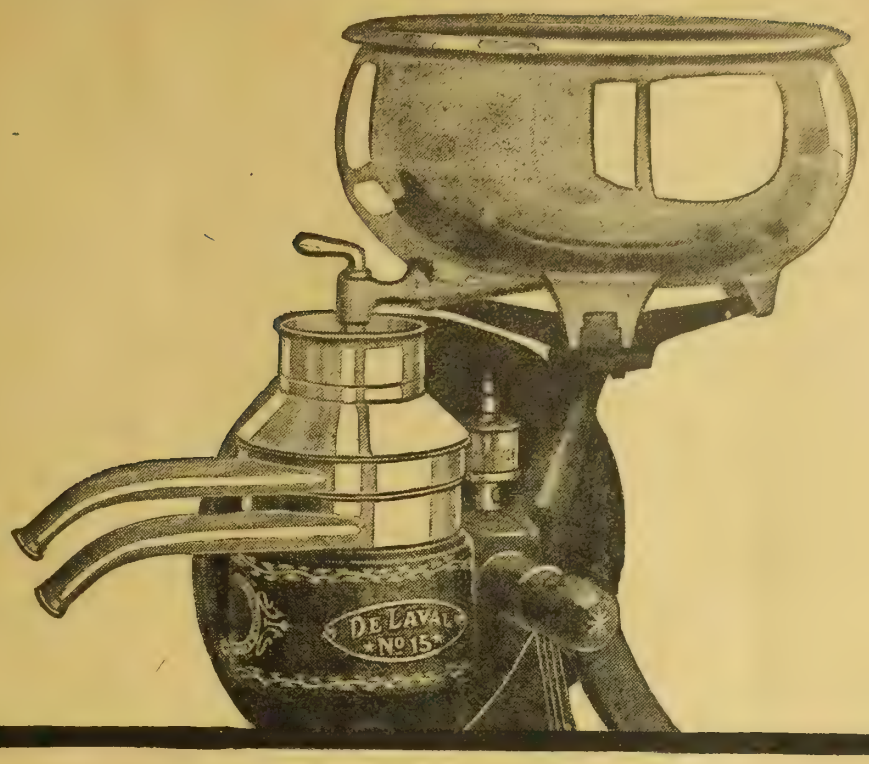
A clean stable will not require as much ventilation as one that is not kept clean, as there will not be so much foul air to be removed. The much dreaded disease, tuberculosis, is greatly encouraged by bad air, by which the lungs are made susceptible to the action of the germs of it, which are carried from place to place, and thus cause the disease in cows that might otherwise be able to resist the contagion.

When one enters the stable in the morning, and feels the air to be warm, heavy and foul smelling, it is a sure sign that immediate ventilation is necessary. This can be done by opening the doors and windows, but ventilation is not perfect until there is some system of automatic ventilation, which keeps up a steady suply of fresh, pure air from the outside, and at the same time discharges the impure air from the inside.

BACTERIA IN MILK

A fruitful source of bacteria in milk is the strainer. Brass strainers are sometimes placed on milk pails. These are often so filled with dried milk that the fresh milk flows thrugh but slowly. Often a cloth strainer is used and washed after each milking. If this is not washed carefully with cold water, then with soap or cleaning powder and warm water and then thoroughly scalded, it becames a prolific source of contamination. The strainer after having been scalded, should be hung in the sunshine to dry and air.

It should be the aim to breed for the largest yield of milk at the time when butter fat is worth the most money. The animal should be allowed a couple of months' rest when butter fat is lowest.



The cream of cream separator prosperity goes to De Laval users

There was never greater need than right now for the best separator, skimming cleanest, having greatest capacity, turning easiest, requiring least care, and producing the most perfect product. In all these respects the De Laval has no equal. Take nothing for granted, simply let it be demonstrated to you. See the local De Laval agent or address the nearest general office.

LIVE STOCK.

SHORTHORN SIRES WILL HOLD THE SIZE

The supreme test of any beef animal is its ability not only to improve the quality, but to increase the size of the progeny of all kinds of cows with which its bulls may be mated, and teh Shorthorn, wherever it goes, carries with it the reputation of maintaining its size even in the hands of carless farmers who are but indifferent feeders. To maintain size under skillfuf selectoin and liberal feeding is quite different from maintaining it where the blood is diluted and the treatment not over generous, but we find the Shorthorn holding its size to a remarkable degree under the hardest conditions.

In connection with this question of size the following table from "Feeds and Feeding," by Henry and Morrison, is a most interesting one:

Age, weight, and daily gain from birth of steers slaughtered at the Smithfield Show, 1895 to 1914.

Breed	No. of Animals	Weight Lbs.	Daily Gain Lbs.
Shorthorn—			
1 year old.....	85	1446	2.14
2 years old	91	1901	1.88
3 years old	4	2363	1.71
Aberdeen-Angus			
1 year lod	93	1416	2.11
2 years old....	86	1848	1.83
3 years old....	2	2066	1.57
Galloway—			
1 year old	72	1229	1.86
2 years old....	73	1655	1.63
3 years old....	2	1794	1.44
Red Poll—			
1 year old	52	1254	1.90
2 years old....	54	1637	1.90
3 years old....	3	1736	1.38

It will be noted that in each section the Shorthorns lead in weight and average daily gain. Size is not everything, but it may mean the difference between profit and loss to the farmer who knows from experience that slow growing kinds are not a good proposition from the standpoint of profit.—G. E. Day, Sec'y D.S.B.A., Guelph, Ont.

HEMORRHAGIC SEPTICEMIA ATTACKS LIVE STOCK

Owing to the prevalence of Hemorrhagic Septicemia which is at present affecting cattle and sheep in different parts of the Canadian West, and cases of which occured in Ontario last year this article by Dr. W. E. Martin, Professor of Veterinary Science, Manitoba Agricultural College, will be of considerable interest to stock owners, and be the means whereby they may recognize the disease should it make its appearance among their farm or range animals:—

In all animals this disease is very infectious. The microorganism belongs to what is known as the Pasteurella group. There is a special germ of the species responsible for the disease in each of the animals susceptible to infection. In cattle the germ is known as Vovisepticus; in sheep the Ovisepticus. The soil becomes infected with the germ; hence susceptible animals are infected through grazing on infected pastures or by fodder grown on such infected lands. Infection, as a rule, takes place through the digestive swstem.

The disease presents itself in four different forms in all kinds of domestic animtls, including cattle, sheep, swine and horses. It has been known to attack poultry, birds and wild animals.

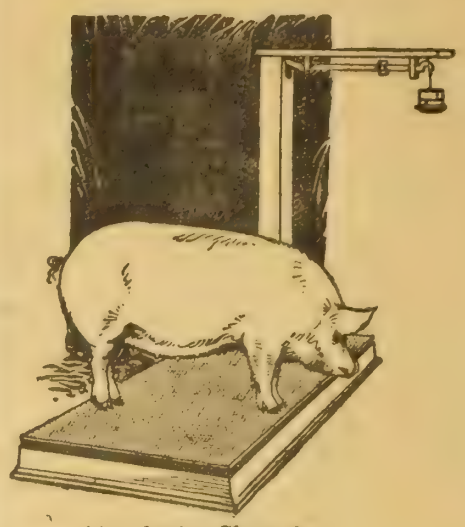
The four different forms are as follows: the Cerebral, Pulmonary, Intestinal and Cutaneous.

The Cerebral form is generally manifested by symptoms similar to blind staggers; animals lost control of their locomotary apparatus, and stumble or stagger into fences or buildings; in fact, I believe, they sometimes are actualy blind from the nervous form of the disease.

The Pneumonic form is characterized by the ordinary symptoms of pneumonia, such as quickened respiration and labored and difficult breathing. There may be a discharge from he nostrils, which in many cases is streaked with blood; the eye lids may be swollen and adhering with a more or less sticky discharge. This form is very fatal.

The Intestinal form is generally manifested by a bloody diarrhoea, which may be of a dark, tarry color. Rapid emaciation follows. There may be evidence of abdominal pain. There may be some delirium, when the animals wil lrun about in an exicted manner. When down, animals manifest severe pains, which is spasmodic. Head an neck may be drawn to one side or over the back. Swellings may appear about the lower parts of the limbs. Bowel discharges are frequently bloody. In some cases there is a discharge of bloody mucus from

Feed for the Quality Prices!



The Scales Show the Quality Feeders

HOG feeding has made rapid strides just the same as everything else on the farm. The old-fashioned method of utilizing mill feeds that happened to be easy to get at low prices, or happened to be handy on the spot, is gone forever. Both experts and farmers now know it pays handsomely to feed an accurately and properly mixed ration. Experiment and experience have shown that careless feeding is one of the causes of poor quality bacon. The markets are demanding higher quality standards. There are attractive profits if you can reach the standards required. You can do it with

Monarch Hog Feed

It is a perfectly balanced ration of corn products, shorts and digester tankage—a rich feed, but not too much so to feed alone.

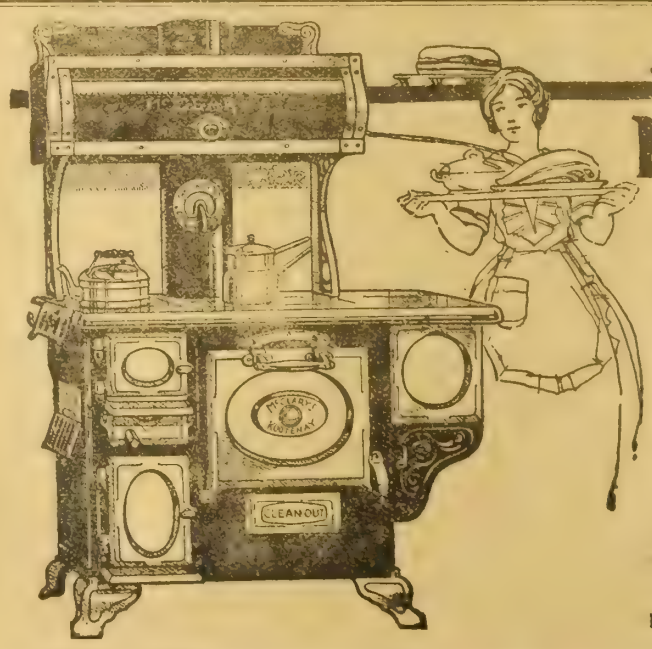
It gets hogs to market in shortest time, at least cost of production. It means heavier hogs sent to market in best condition for selling. It is easily digested. Hogs fight for this palatable feed. Guaranteed analysis: protein 15%, fat 4%.

Mill feeds are often hard to get, but Monarch feeds—ready for use—are always obtainable. Order a ton from your dealer. If he cannot supply you, write us direct, giving dealer's name.

MONARCH DAIRY FEED
has guaranteed analysis of 20% protein and 4% fat. It is a properly mixed combination of Oil Cake Meal and Cotton-seed Meal with the bulky feeds, bran and corn meal. Though very rich, ensuring splendid results, it can be fed alone.

SAMPSON FEED
This general purposes feed is somewhat similar to Monarch Hog Feed, except that oil cake meal is used instead of digester tankage; it gives results for both cattle and hogs. Guaranteed analysis: 10% protein and 4% fat.

The Campbell Flour Mills Co., Ltd., West Toronto 15



McClary's Kootenay

DO YOU realize how much time you can waste over a cranky range?

Every busy woman should have a Kootenay to work with—grates easy to work, ashes easy to take out, oven quick to respond, doors fitting right, a well-made reliable range.

Limited
Hamilton, · Canada.

the nostrils. This form is also very fatal.

In the Cutaneous form there is usually more or less welling in the region of the fore quarters, throat, and dewlap. The swelings, as a rule, are not very extensive. Anomals that are inclined to feed swallow with difficulty, if at all. In milch cows the seretion of milk is arrested. There is a general indisposition.

In certoin animals of a herd the symptoms of the four different forms of the disease may be present at one time; in others the symptoms of two or three forms may be combined.

The disease in acute form may cause death in from twelve to forty-eight hours.

As a means to preventing the spread of the disease, healthy animals should be removed from the sick ones, and from infected places to premises known to be free from the disease. Infected places to premises known to be free fro mthe disease. Infected places should be thoroughly disinfected.

Fatal as the disease is when left uncontrolled, it can be stamped out and many of the sick animals saved by the use of Bacterins prepared especially to combat the disease. There is a special Bacterin (Vaccine) for each species—cattle, sheep and swine.

In cattle Hemorrhagic Septicemia may be confounded with Blackleg if due care be not exercised in making correct diagnosis. Blackleg usually attacks animals from four months to three years of age. Hemorrhagic Septicemia, while attacking mostly young animals, also affects adult or older cattle. In Blackleg there is usually well marked lameness in one or more legs, due to large swellings of the quarter of the lame limb. If the hand be pased over these swelings a crepitating sound is heard, due to the gas formation in the tisues. In Hemorrhagic Septicemia the sweling if present, is of slight dimensions and seldom crepitate; and if the animal is lame, the lameness is not accompanied by extensive swellings. In Blackleg the body temperature is high at the onset of the disease. In Hemor rhagic Septicemia the temperature is usualy normal at the commencement but becomes high as death approaches.

In some outbreaks, individuals of a herd may be affected with both diseases at the same time. Where there is any doubt as to whether a herd is affected with only one or with both diseases all animals between the ages of four months and three years should be promptly immunized with the Blackleg Filtrate and at the same time these and al other animals of the herd should be vaccinated with Hemorrhagic Septicemia Bacterins.

Hemorrhagic Septicemia in sheep is a disease that follows the raising and feeding of large numbers of sheep in almost every country. It is not so prevalent in the newer sheep raising areas but once it gains a foothold, it spreads rapidly and firmly establishes itself on the premises, from which it is very difficult to remoee the infection, as the causative organism lives in the soil and around shelters.

The symptoms in sheep vary as do those in cattle, but the most constant and convincing symptom is the rapid spread of the disease, with a large percentage of the cases dying in from one to six days.

The post mortem in all species of animals varies with the form of the disease the different animals have. There are always more or less red spots from the size of a pea to a walnut, to be found in the lining of the wind pipe, in the lungs and heart. In the Intestinal forms these red spots are found in the intestines, omentum, and peritoneum. In the Subctuaneous form the ered spots are immediately under the skin. In the nervous form the blod spots will be located in the brain and spinal cord. The blood has always a peculiar reddish-purple color when spread hinly over the hand or other white surface.

The carcasses of animals which have succumbed from the disease should be either deeply buried or cremated, the latter being the safer means of disposal of the carcass. Stables and sheds which have been occupied by sick animals should be thoroughly cleaned up and disinfected; al litter and refuse should be burned.

When the outbreak occurs, no time should be lost in procuring the vaccines, or serious losses will result.

Bright Prospects

It looks as though the demand for beef will be strong for some years to come, and the man who is in line for greatest profits is the Shorthorn Breeder.

We haven't room to give our reasons here, but write the Secretary for our free publications, which furnish facts.

MONTREAL PETERBORO WINNIPEG VANCOUVER

FIGHTING FLIES WITHOUT DOPE

Dairy farmer from Stormont county, Ont., informs the Ottawa Farm Journal that a year ago he tried to fight the fly pest with spray "dope" in his cow barn, "but," he says, "my hired man complained that the flies transfered their affections from the animals to himself. Now and then we had complaints, also, that the milk had a 'dopey' flavor. Furthermore, it was just one more item to be looked afted—the spraying of the animals. We used about half a barrel of the stuff, I guess, before it occurred to me that it would be cheaper to screen the doors and windows. Then we cleaned up the place also and permitted no manure to stand over two days, before being taken away. We didn't see much difference that season because we got too late a start on it but we followed the same process last spring and summer. There wasn't one fly around the stable to where we had a hundred the year before. 'Dope' may be a splendid thing to put on the animals in the morning after milking. It may keep them from being annoyed during the day. But the screened stable and the clea nbarnyard constitute the only effective way of fighting the fly evil so as to provide creature comfort for both men and animals at milking time."

EMPIRE MILKING MACHINES

Add Hours to Your Day

AN Empire Milking Machine will enable you and your help to spend at least two hours more in the field every day. The absolute uniform action of the Empire Milker soothes the cows and generally results in considerably greater milk flow. It also lengthens period of lactation.

If you milk ten cows or more you *need* an Empire. It will positively save you money 365 days in the year. Investigate, Write for Catalog No. *26* Ask for name of nearest dealer. Start saving now.

THE HORSE

TEETH OF THE HORSE REQUIRE SPECIAL CARE FROM TIME OF HIS BIRTH

Every horse that gets thin or out of condition, without fever, or any other apparent cause, should have his teeth and mouth carefully examined, and especially if he drops some of his food while eating. without any indication of a sore throat, or if he holds his head somewhat on one side, in order to get the food between the outer edges of the teeth.

Very little attention is paid to the teeth of the horse by the average man who owns horses. Many farmers who have a keen interest in the welfare of their horses and are careful with the feeding and general comfort of their animals, are often disappointed with the results, as seen in the dry haired, unthrifty condition of horses, which overtake their efforts. An examination of the mouth and teeth would in most cases reveal the cause of the trouble, but it is only the horse owner who has a knowledge of what takes place in the horse's mouth, from birth to five years, then can intelligently examine the mouth.

The Masticating Process

The food of the horse must be ground; simple bruising and champing would not reduce it sufficiently small for the purpose of digesting, Simple champing, which is the motion of the human lower jaw, and that of beasts of prey, would very imperfectly break down the grass, the hay or oats that form the horse's food. It must be put into a mill; it must be actually ground, and without this process being done thoroughly there is going to be trouble with the horse's digestive organs. The man who cannot tell by sound when the horse's teeth are not performing their functions properly when chewing, has something to learn in horse care. He has to cultivate the "ear" to detect the healthy grinding rhythm from the champing sound arising from disordered and defective chewing.

The joint of the horses's lower jaw is admirably adapter for the purpose which the horse requires. It has both the simple motion of a hinge for nipping the herbage, and seizing the hay or oats as well as the lateral or grinding motion to bring the food into a pulpy condition to fit it for digestion.

The Full Mouth

The jaws contain the teeth, which are the millstones in the operation. The mouth of the horse at five years old contains forty teeth, viz., six cutting teeth in front, a tusk on each side, and six molars, or grinding teeth, above and below; they are contained in cavities in the upper and lower jaws, surrounded by bony partitions, to which they are accurately fitted, and by which they are firmly supported. For a little way above those bony cavities, they are surrounded by a hard substance called the gum, so dense, and adhering so closely to the teeth and jaws, as not to be separated without great difficulty. It is singularly compact, that it may not be wounded by the hard sharp particles of the food and almost devoid of feeiing, for the same purpose.

The term, nipper, expresses the action of the two front teeth. Whoever has observed a horse in the act of browsing and the twitch of the head which accompanies the separation of each portion of grass, will preceive that it is nipped or cut off. The growth of the nippers in the foal should be watched so that the teeth markings are understood. At the age of one year and a half the mark in the central nippers will be much shorter and fainter; that in the two other pairs will have undergone an evident change ,and all the nippers will be flat. At two years of age all this will be more manifest. About this period the fifth grinder or molar tooth will push out, and likewise another process commences that invariably gives the young colt trouble.

The Change as the Animal Grows

The first teeth are adapted to the size and wants of the young animal. They are sufficiently large to fil' the colt's jaws; but when the jaws are expanding with the increasing growth of the animal, the teeth are separated too farm from each other to be useful, and another and larger set are required. This change of teeth commences in those which earliest appeared, and therefore the front or first grinder gives way at two years of aeg, and is succeeded by a larger and permanent tooth. In a few instances, however, the second teeth do not isre immediately under the temuorary milk teeth, but somewhat by their side; and then instead of this gradual process of absorption and disappearance from the root upwards, it is only pushed a little out of its place to the fore part of the first grinder and remains for a considerable time under the name of wolf's teeth, causing swelling and soreness of the gums and frequently wounding the cheeks.

During the period between the falling out of the central milk nippers and the coming up of the permanent ones, the colt having a broken mouth, may have difficulty in grazing. If a colt falls away in flesh at this time. it is due to the condition of its teeth, and soft foods should be given.

The tusks are four in number, two in each jaw, situated between the cubbing teeth and grinders, much nearer to the former than the latter. and nearer in the lower jaw than the upper. In shape the tusk resembles a cone, it protrudes about an inch from the gum, and has its extremity sharp pointed, and curved. At the age of four to five years the tusks are peculiar to the horse; mares, however, have the beginnings of them in the chambers of the jaw, and only appear externally in some old mares. There are, however, some mares that have them developed while young, but these mares on the average never prove good breeders. Some mares have trouble with the undeveloped tusk al their life time, and it is generally aggravated by the bit.

The use of the tusks is not evident; perhaps in the wild state of the animal they are weapons of offence; so

that he can more firmly seize, and more deeply wound his enemy. The horse breeder often attempts to hasten the appearance of the tusk, and he cuts deeply through the gum to remove the opposition which that would afford. To a great extent he succeeds in causing pain and does not gain much in point of time in their appearing. Only in specially bad cases from inflammation arising from the growth of the tusks should the knife be used. The resistance of the gum is not like that of a solid and firmly fiexd tooth, and is much more easily overcome by the regular process of nature.

During these important changes of the teeth of the horse, the animal would suffer very little inconvenience if it were not for the fact of his being subjected to domestication and work. This fact should command colser attention by all horsemen, for the teeth of the horse are more necessary to him than those of other animals are to them. Cattle feed gets a second chance, and so also does that of sheep, the dog can bolt his food and thrive on it, human foods are carefully prepared before they are eaten, but the food of the horse must be well ground down, or nutriment cannot be extracted from it.

CURING A REARING HORSE

A writer in Rural New Yorker tells of buying a three-year old colt some twentw years ago. "It had been broken single in the Spring and then been turend out to pasture," he says. "In late summer I traded a work horse for the colt to drive to my work, two miles. I could not stop two seconds before said colt would throw up her head, and if I did not let her go, would rear up on her hind feet, and many was the time I would think she was going to fall backwards. I drove a two-wheeled cart or sulky, and I would step out on the axle so I could wait for her to come down, one way or the other, and only wished she would break her neck and be done with it, as nobody wanted her. My wife would hold her while I hitched the last tug and jumped on the seat; then she would jump one side to keep from being run over. I was doing carpenter work for a groceryman, and he helped me to hitch up at night and gave me advice as to how to handle the horse, which advice I did not take at all, as I was brought up on a farm and thought I knew more about horses than he did. I also thought he had never seen his remedy tried, was just imagination; it was so simple it was foolish to try it. It was to whirl her around, make her dizzy. Well, I thought it was bad enough going ahead without a whirl-around horse.

"In finally finished his work and went to work in another part of the city, and I could get no one to help hitch up. I certainly did have a circus hitching up alone. After about four weeks I met the groceryman one evening as I started for home. I stopped, and it was no time before she was standing on her hind feet. He said: "Have you whirled her around any?" I said nno. He said: "Don't baby that colt any longer; ;p;ut the bud to her and whilr her around till she wil stand; that is the way they break running horses." By that time I was out of hearing, but it flashed through my mind I had never seen a running race but that some of the horses couldn't be kept from making a dash onl yby keeping them circling around back of the starting line. When within one-half mile of home I stopped, and at first sign of rearing up I gave the word to go, pulled hard on the left line and laid on the whilp on her right side just onec. She went around so quick two or three or four times it made me dizzy, and she st ood with her front feet spread out as though afraid of falling down. Before I got home she would stand till I told her to go, but the next morning she tried once as I got on the sulky and I would not let her go to rear up, but as I pulled the left line and put the whip on her and whirled her around she stood for me to get off and on the cart as many times as I had a mind to, and the fight was over. I kept her two and a half year, and never knew her to rear up again, no matter how long I wanted her to stand."

A WASH TO SAVE HORSES' SHOULDERS

What shoulder wash would you recommend for horses to keep them free from sores when at heavy work?

The application of a wash of tannic and alcohol is highly recommended to save work horses from shoulder troubles. It is made up by a mixture of one-fourth dram of tannic acid and four ounces of denatured alochol combined with water until the tannic acid is dissolved. This wash should be applied to the horses' shoulders night and morning. Shake the solution well before using. Or a solution of about one teaspoonful of salt to a pint of water may be used in the same way.

The advantage of either of these applications is that they are astringent; that is, they contract the tissues. If they are applied regularly for about the first month after the horses being to work there will be no trouble with sore shoulders.

KEEP HALTER TIGHT

A simple device to tie the horses in the stable eliminates the danger of an animal's getting his leg over the halter rope and possibly injurying himself, or least causing me quite a bit of trouble in getting him loose.

I take a block of hard wood four to six inches wide and two inches thick and drive a heavy staple into it, or screw in a large screw eye. Then I run the halter rope through a hole in the manger and tie it to the staple or screw.

When the horse's head is lowered the slack is taken out of the rope and it is kept tight all the time.—G. H. Long.

FLEET FOOT
FOR STURDY WEAR

Put the boys and girls in FLEET FOOT shoes this summer. They can have two or three pairs of FLEET FOOT for the price of one pair of leather shoes. The low price of FLEET FOOT and their sturdy wear, make them the most satisfactory and economical summer shoes you can buy for children.

The Best Shoe Stores Sell FLEET FOOT.

POULTRY.

SUCCESSFUL DUCK RAISING

Farmers' Bulletin No. 697 of the United States Department of Agriculture, deals with duck raising. From it the following information for the duck raiser is taken:

Pekin—A large white duck of Chinese origin, favored by comercial duck raisers who make a specialty of producing green ducks; it is also the most popular breed on general farms in the United States.

Aylesbury—A large, white duck of English origin; less popular than the Pekin.

Rouen—A variety of French origin of gray claret and green coloring, with a white ring around the neck. A good duck for general farms.

Indian Runner—A variety of Dutch or Belgian origin, smaller than the other three above described; belongs to the egg-laying class. Indian Runner ducks are good foragers, non-sitters and hardy. It is a good breed for the general farm.

Selecting and Mating

Ducks on regular duck farms are usually mated in flocks of about 30 females to five or six males. Select ducks with short necks, medium long bodies, flat backs and a good depth to the keel bone. Watery eyes are a sign of weakness. Confine laying ducks in the pen until 10 a. m. or their eggs are liable to be lest.

Incubation

The period of incubation is 28 days. Duck eggs may be hatched under the duck, by hens or incugators. Strorg, fertile eggs are eessential to good hatching. Observe the usual precaution when hatching under hens, give a hen nine or ten duck eggs, keep her free from lice, and sprinkle the eggs with warm water previous to hatching. Ducklings require from 24 to 48 hours to come out after they pick the shell. With incubators, operate as per the manufacturer's instructions. Duck eggs require more moisture during incubation. The machine should be kept at 102 Fahr. for the first three weeks and 103 Fahr. for the last week.

Feeding Ducklings

Ducklings do not need feed until they are from 24 to 36 hours old, after which they may be fed five times daily on a mixture of equal parts by measure, of rolled oats and bread crumbs, with a 3 per cent, mixture of sharp sand mixed in the feed Abut the third day this feed is changed to equal parts bread, rolled oats, bran and corn meal; after the seventh day to three parts bran, one part each of low grade wheat flour and of corn meal, 10 per cent. of green feed and 5 per cent. of beeef scrap, with about 3 per cent. of sand or grit in all the rations. Feed four times daily after the seventh day until the ducklings are two or three weeks old, when they need be fed only thre times daily. After the ducklings are about a week old, the grit or sand may be fed either in the mash or in a hopper, but the common practice is to feed grit in all duck rations. Beef scrap is not usually fed until the ducks are a week old, when about 5 per cent. is added tothe ration, which amount is gradually increased 15 per cent. by the end of the third week. This feeding is for ducks intended to be sold "green" when form 8 to 12 weeks of ge. Ducks being raised for breeding or for later marketing should be given plenty of green feed and vegetables. If milk is available at profitable feeding prices it may be used as a part of the rations. Milk fed ducklings demand highest prices.

HOW TO IMPROVE QUALITY OF THE EGGS

It is remarkable how few farmers appreciate the importance of infertility in market eggs. The removal of the male bird from the flock does not necessarily guarantee the absolute preservation of its good quality, but such an egg, being free from the active germ, will not, under ordinary storage conditions, deteriorate seriously. It has been proven beyond doubt that the great bulk of eggs which are spoiled for purposes of consumption are fertile eggs, which have been subjected to heat above seventy degrees, and thus have undergone partial incubation. If the heat is continuous and strong enough the development of the chick will continue; but if it ceases or is intermittent putrefacation at once sets in and the egg comes bad. Such eggs wil show black spots, blood rings, or will be rotten, depending upon the degree of deterioration the have undergone.

Few farmers have much knowledge of these facts, consequently they make practically no effort to insure the infertility of the eggs produced upon their farms. They seem to have the erroneous impression that the presence eof the male bird is essential to the production of the maximum number of eggs; but such is not the case, and it has been proven beyond all question that such an arrangement is not necessary or desirable.

Therefore, in view of the above, it will be easily seen that the male birds should be discarded after the breeding season is over. They will sell for a better price then than any time later on. If the male is a valuable breedinb bird and he is wanted for use another year, he should be kept separate from the hens until the warm weather is over at least. He will then be out of the way and not able to annoy the rest of the flock.

TEN LEGHORNS LAY 10,000 EGGS

A remarkable instance of productivity in fowls is found in the record of ten White Leghorn hens at the Ohio experiment station which have produced 10,000 eggs. Two of the hens are nine years old, six are eight years old, and two are five years of age.

The "ace" of the lot, "C-34," has 1,179 eggs to her credit; she is followed closely by "C-38" with a total of 1,147. The other eight followed closely in production. Two of the hens are from an original lot of pullets purchased in 1909 when the poul-

SARNIA
POULTRY FENCE

The Canadian farmers and ourselves have been friends for more than eight years. Our business relations have been very intimate and profitable both ways—to the farmer and to us. We have given full measure of service—real fence value. That means repeat orders. Once a Sarnia fence customer, always a Sarnia fence customer. That is especially true of Sarnia poultry fence. You get real fence value, durable and strong, with all extra profits eliminated, when you deal direct with us on our Factory to Farm one profit plan.

We Save You Money

Buy no Poultry fence any part of which is made of light wire. The life of the fence will only be the life of the lightest wire. A chain is no stronger than its weakest link. The Sarnia knot—in fact all parts of our fence are made of the same size wire. We guarantee the Sarnia fence to be made from Government guage, high grade wire that stands the acid test, and to be the most perfectly woven Poultry fence on the market. Western Canada supplied from Winnipeg. Get our low price list and descriptive literature before you buy Poultry Fence Address nearest office.

Canada's Best Poultry Fencing
The shut-in and shut-out Fencing—a poultry fence strong enough to withstand the combined weight of two big horses. And that without a top or bottom board either. Our lock is the secret of its strength—a real protection to large fowls and little chicks too. If you are interested in such fencing, write us. Ask for our literature. We also manufacture farm fence and ornamental fencing and gates. Dealers nearly everywhere. Live agents wanted in unassigned territory.
THE BANWELL-HOXIE WIRE FENCE CO., LTD.
Winnipeg, Man. Hamilton, Ont.

try investigational work was begun at the Ohio Station.

None of the hens showed any particular effects of old age. While their annual producion is less than during the earlier laying periods, they still lay regularly during the spring and summer months. Each of these hens has produced approximately $25 worth of eggs, at ordinary market prices, at a feed cost of about $10.

BEST FIVE YEARS IN POULTRY HISTORY JUST AHEAD

Scarcity of Products in Europe makes Present a Most Propitious Time for Enlarging Flocks in This Country

(By H. W. Sanborn, Extension Poultry Husbandman, U. S. D. A.

Now is the beginning of the best five-year period for profitable egg-production ever known.

We ebelieve it will be the best five years that will ever be known.

All Europe has very little poultry. Some parts none at all.

All Europe will become a bidder in American markets for poultry and eggs.

American breeders must furnish the breeding stock for the renewal of the European flocks.

It will take at least five years before Europe can be selfsustaining in poultry products.

These facts make for continued high prices of poltry and poultry products, even after prices of grains have declined.

This means that farmers will be able to realize for the next five years more for the grains fed to hens for egg production than will be possible by and other process of marketing. We feel confident that by following proper practices in poultry keeping at all seasons of the year that double the market value of grains may be realized by the feeding of it to hens for egg producton.

Begin now—this season—to make your poutry work count. Give it a definte place in the daily work, keep accounts and compare returns for effort expendeed with other farm operations. If this is done results will be more evident and you will appreciate your poultry as revenue producers.

Practice right selection in breeding.

Provide proper housing conditions.

Feed liberally rich foods to obtain high egg yield.

Hatch early. Early hatched pullets lay fall and winter eggs.

Practice good sanitation.

Keep hens free from lice and roosts free from mites.

Take good care of eggs, gather daily and market often.

The hen lays a perfect egg. Seee to it that a perfect egg goes to market. Good eggs bring top prices.

PREVENTING HIDDEN NESTS

During the summer season when grass, weeds and other vegetation are tall, many hens persist in stealing their nests away and laying in secret and obscure places. Chances are the hen that hides her nest is apt to come back with a brood of chicks and raise them with profit, provided it is not too late in the season. Frequently eggs laid out are entirely lost. They may rot, or be stolen by wild animals, crows, etc. Many, if found at all ,are eso stale that they are unfit for use.

There are several ways of preventing hens from stealing their nests. The best way, all things considered, is to have the place free from weeds, rubbish, etc., so that no hen can find a secret place to make a nest. This can be done quite easily. Weeds should be mown. It is a good plan to have several sheep to turn in occasionally. They will keep the weeds down, if turned inat the right timie. Sheep are better than other stock for they will not injure the trees in the yards. Rubbish should be collected and either burned or disposed of in some way.

Another good plan is to have a large hen-tight poultry-yard in connection with the hen house, and to keep the laying hens in it until about three o'clock in the afternoon. By this time the majority will have laid, and they may be turned out on range. This will allow them several hours for exercise. The eggs will all be laid in the hen house, and they can be gathered fresh every day. You will also know where to look for them. Where no such pen is at hand, and the yards are clean of weeds and rubbish, and the hens still persist in searching for secret nesting places, try putting up a few nests in out of the way places. Perhaps they will find and use them.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N B. solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

LET US SMILE!

The thing that goes the farthest
Toward making life worth while,
That costs the least and does the most,
Is just a pleasant smile;
The smile that bubbles from a heart
That loves its fellow-men
Will drive away the cloud of gloom
And coax the sun again;
It's full of worth and goodness, too,
With manly kindness blent
It's worth a million dollars
And it doesn't cost a cent.

BUSINEES IS BUSINESS

(By Zona Gale.)

In the dining room where Burton and his little daughter sat, a high gas burner poured light that showed the room minutely, indelicately, as if the light had taken things unaware. It was two weeks since Mrs. Burton died, and already the room looked different. A window-shade had "gone over the roller" and bared a blank night window; the bird cage hung uncovered at a level with the blaze of the burner; newspapers were piled where she would not have piled them.

"I hear Heilman's going to sell this place," Burton said. He was heavy, thick-fleshed, unshaven, coatless; but his eyes were kind, as was his voice.

Mary, the little dauhter, was ten years old, with a startled, pointed face, and with hair braids of uneven strands as if she had plaited them with unaccustomed fingers. She had a way of putting her hand to her cheek as if to cool its flush, and this she did now. "Would we have to go 'way from this house then?" she asked her father.

"Sure," said Burton, "sure thing."

"And leave where Mamma died?" said the child.

Burton nodded without speaking. He and his wife had furnished the house before their marriage and had come to it on their wedding day. Some of the furniture stood now where it had stood then, and where they had pictured it when in that week in which Burton had had his "raise," making the marriage possible, they had first visited the empty house together, had said to each other that this would be home, had looked at each other in a divine and understanding whose only visible sign was bashfulness. And in these ten years there had grown about the place the roots man strikes for himself—the trees that Burton had planted, the shed that he had built while his wife worked in the kitchen or caled to him from the portch, the cistern he had filtered, the shelves he had put up, the painting he had done—all wrought on an economical basis of rent saving, and all fruitful of the enduring spirit incident to home building. And here Mary had been born, in the room off the dining room where they now sat, and on the casement of the door into that room he height was measured and marked in ink, ten times.

"Oh, Daddy, you buy the house!" Mary cried.

Burton shifted his heavy feet on the high fender. "God knows, I wish I could!" he said. "I could give him eighteen hundred dollars for it—and I would. But he'd never take it."

"Eighteen hundred dollars!" said the child. "Daddy, surely he'd take all that money if you asked him to."

Burton shook his head. "I don't believe it," he said. "I met him today. He mentioned he'd be in tonight. I s'pose he's coming to see about selling—and he'll be hot for every cent. I thought I'd try him for eighteen nundred, but it won't do any good.

"'Maybe it will," said the child.

When, in a little while, Abel Hellman came in he had with him his wife—a gaunt woman, her face filled with her years, her hands modified to many a life-long task. She greeted Burton and the child, lifted a pile or newspapers from a chair and sat down behind the stove, turning back the hem of her dress to dry. Mary brought a stool and sat beside her, but they said nothing, and merely stared into the red coals that occasionally shook softly down through the grates.

The men did the talking, speaking of the town's affairs in the empty, habitual comment which custom breeds to a dreamy contagion.

Abel had a hand from which the four fingers were missing, and with this hand he continually made gestures. "I've made up my mind to sell this place," he said at length.

"So?" Burton said.

"I've had an offer of two thousand for it," said Hellman.

Burto nnodded. "Best take up with it," he said.

"Think so?" inquired Hellman. "Why is that?"

"Place ain't worth fifteen hundred," said Burton.

Mary turned from the coals and fixed her eyes on her father and listened.

"It's worth the full two thousand to anybody that knows property," said Hellman insolently.

"Think I don't sense 't you'll be taxed for sewage if the reform folks get in?" Burton demanded. "Think I don't know the house is falling to pieces over us? You ain't half kep' it up, and you know it, Hellman."

"Well, you had to have water put in, like a dock," said the landlord. "I couldn't afford shingles too. You've been an exactin' tenant, Burton, that you have."

"You've been a holy old tyrant then," said Burton, "and the neighbors know it. I'll be glad to be rid of ye. When do you sell?"

"I'm to let the man know tomorrow if I take up with his offer," Hellman answered.

"You'll want us out of here in a month like?" Burton asked.

"Not longer," Hellman told him.

Burton tipped back his chair to the points of the rockers and sat with his hands locked behind his head. "I'll be looking for a little place," he said.

On her stool by the stove the child sudenly leaned forward and sobbed in her curved arms lifted to hide her face.

"Why, Mary!" Burton said in concern, "what ails ye? Did you hit ye on the fire?"

"Don't let it go, Daddy, don't let it go," she begged.

"Tut, now," said Burton kindly, "this ain't a thing you know about,"

The child went and stood beside Abel Hellman. "Couldn't you leave him have the house?" She said. Just now he wish't he could buy it. Mother lived here. She died here. We can't either one of us bear to see it go."

Hellman glanced shrewdly at Burton. "He ain't been talking exactly that way," he said.

The other man flushed dully. Hellman was swift to take advantage.

"If you feel like that about it, Burton," he said, "I'll tell you what I'll do. I'll let you have it for nineteen hundred. I'll knock a cool hundred off to oblige."

Burton stretched himself back again to the length of the rockers, "What about the fellow that's offered you two thousand?" he asked with a leer of the eyebrows and a loose lip and a look that made of him someone else.

Hellman moved his feet about, threw out his fingerless hand—it was strange how the maimed thing could make a gesture of grasping.

"Well, he ain't as prompt pay as you are," he said, "an' he was only goin' to give me two hundred down. I'll leave you have it for the nineteen hundred—say, five hundred down and the rest fixed to suit."

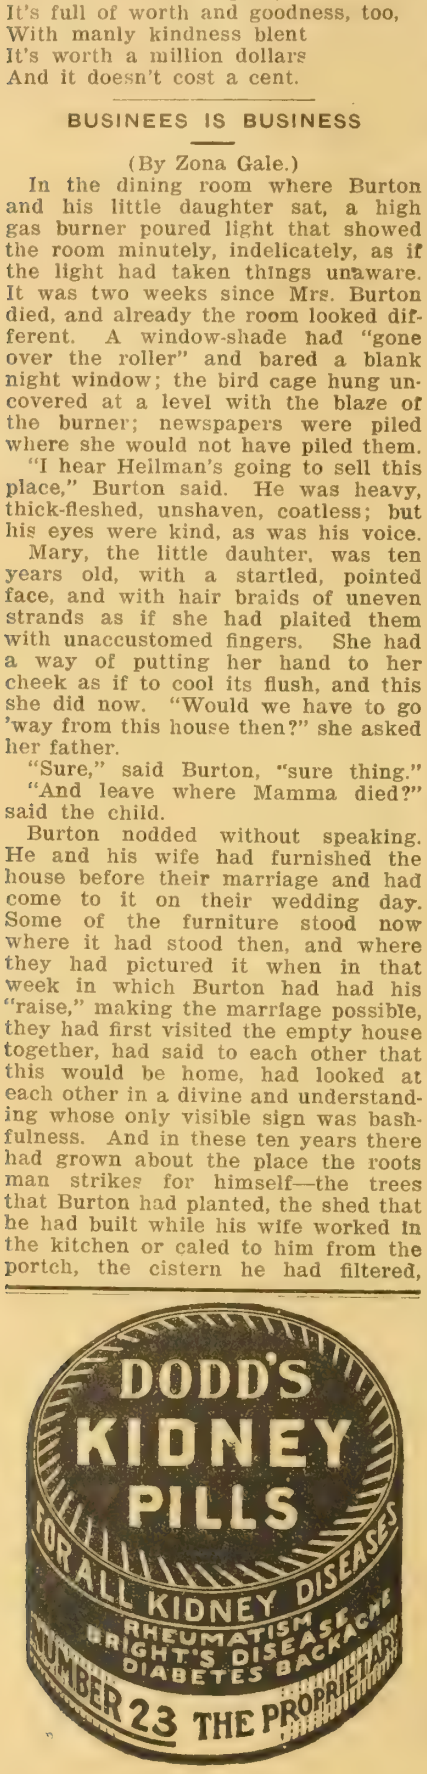
"I won't give you no ninteeen hundred," said Burton stubbornly. The place ain't worth a cent over fifteen at the outside. Not with the repairin' that's needed, and the sewage acomin' on, an' the Interurban gone off down Chestnut street."

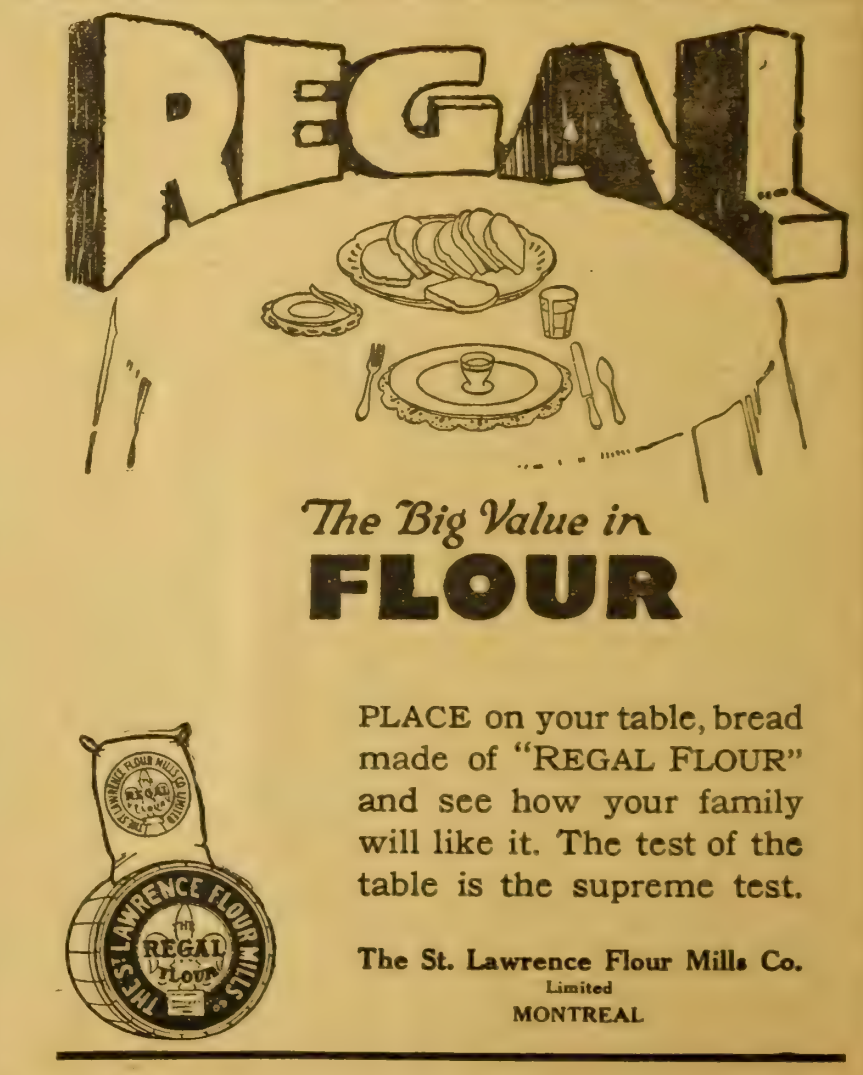
They were silent for a moment. Hellman's wife sat snapping the hem of her skirt to dry it out. The skirt was bodiless, as if the life had long gone out of it. She sat by the stove waiting Hellman's motion to go; she was clothed in the little with which he had clothed her, worn with the work of his home, spent with the bearing of his children; but her dignity was as definite as the dignity of wisdom and of other eternal things. She was looking at Mary, who had turned to the coal stove and stood tracing the pattern of the nickel, the red coals glowing on her face, where the tears lay.

Helman looked at the child too, and narrowed his eyes. "Your ma set a good deal o' store by this place, I guess," he said to her.

Mary nodded her head, with three little intaken breaths.

"eYs," Hellman went on. "I recollect her running out of the gate a





PLACE on your table, bread made of "REGAL FLOUR" and see how your family will like it. The test of the table is the supreme test.

The St. Lawrence Flour Mills Co.
Limited
MONTREAL

little while ago, to speak to me when I was goin' past. I recollect she wanted a little addition put on so's you could have a room to yourself. She said she could do the paperin' and your pa was goin' to build in a bureau out of a packin' box. I couldn't see my way to it, but I noticed what a lot of store she set by the place. The front yard must be full o' stuff she's planted and set out."

The child put her hand to her face and stood silent.

"Yes," said Hellman, "I expect it'll take you quite a while to get used to anywhere else, you'd all been here so long together. I use' to see you all setting by the table evenin's—here in this room. That your ma's rocker?"

The child nodded mutely.

"You ain't disturbed much out of place from where she left it, I reckon," Helman said. "The kitchen now and the butt'ry—just as she le 'em, eh?"

The child nodded.

"Her room just the same is it—the room she died in?" Hellman inquired. "Kind o' tough to have to move out o' that."

The child had receded two steps or three and stood against the casement of the door, where the ten ink marks had measured her growth, outside the room where she was born. She threw a nappealing glance at her father—but Burton sat looking into the red coals, his lips moving in some laborious reckoning. She looked toward Hellman's wife, and something in the woman's face answered, and the uhild sobbed: "Some things we ain't had down out o' the closet since she hung them up on the hooks."

"I expect not," said Hellman; "I know how it is. Pity your pa feels he has to let it go. I'd like to leave you in here a little longer on account of sentiment. But I s'pose maybe he knows best. Well, I guess I'll be going along now. Best wipe up your eyes, little one. It can't be helped, it seems. Good-night, Burton. It's a good bargain you're turning down at ninteen hundred."

"Fifteen hundred," said Burton. I'll give fifteen hundred. Not a cent more."

The child stood by the door crying silently.

nI the corner Hellman's wife dropped the hem of her skirt and got to her feet. "That's all right," she said deliberately. "Abel is satisfied with the fifteen hundred, ain't you, Abel?"

Helman glared at her, but she did not meeet his eyes. She was looking at the child, to whom she moved somewhatnearer, and gave some unimportant touch to her black hair-ribbon.

"You said this morning that fifteen hundred was all you expected to get out of the place, you know," the woman went on clearly. "Best to tell him so, and get it settled tonight."

"What do you know about this?" Hellman snarled. "You keep out o' this, will ye?"

Hellman's wife put her hand on the child's shoulder and faced the men. "We've set by hearing you do business, Mary and me," she esaid, "and I guess we know you are liars, the both. The child here let out that you're breakin' your heart, Matthew Burton, to keepe the little house. Well —I've set for years heard Abel say a thing was worth more'n he knew 'twas worth, and tell why, and cover the truth that didn't further him. I've seen him look a man in the face and act indifferent about sellin' when the need to sell was prickin' him sore. I've heard him tell one, and another, and another, this when he meant that, and that to cover up the truth o' this —well, he's counted a smart business man, I hear 'em say. I know him different. I've been contented to share his gainin' to keep the bread inside my bones and the children's, but I've never see him spin sobs out of a child before. That's why I've let the truth out on him a-purpose—just like your girl, Matthew Burton, has let it out on you unmeaning. You're fine business men, I s'pose, the both o' you. But I don't see and I guess the child here don't see—how in the name of truth you're any holier than common liars."

The two men had risen. Burton was looking steadily at Hellman, whose face suddenly went into an ugly twist of laughter.

"Listen at that," Hellman said. "Ain't the women the devil's own? They can't understan business any more'n a colt. She don't know what she's talking . . . I tell ye what I'll do; I'll sell out to ye, Burton for eighteen hundred; and I'll tell ye what else I'll do; I'll pay the sewer tax. Now what's fairer than that? Come."

Burton stood shaking his head, his lips pressed thin, his eyes locked doors.

Mary went to her father and slipped her hand in his, thrust half into his pocket, and looked up radiantly in his face. "You said you'd give eighteen hundred dollars, Daddy," she said; "why don't you tell him so?"

Then the two men looked swiftly in each other's faces, and for a moment of time the anxious, waiting spirit in

HOT PANCAKES!

Yes, But-- What are pancakes worth without syrup? It is the syrup that gives the flavour; and there is no other syrup that tastes just as good as

CROWN BRAND CORN SYRUP

For hot pancakes, hot biscuits and muffins, and a dozen other Table and Kitchen uses, housewives with the widest experience use Crown Brand, every time—the golden syrup with the cane flavor.

For Marmalade and other preserves, we recommend our LILY WHITE Corn Syrup.

A MESSAGE TO WOMEN!!

LET a woman ease your suffering. I want you to write, and let me tell you of my simple method of home treatment, send you ten days' free trial, postpaid, and put you in touch with women in Canada who will gladly tell what my method has done for them.

If you are troubled with weak, tired feelings, headache, backache, bearing down sensations, bladder weakness, constipation, catarrhal conditions, pain in the sides, regularly or irregularly, bloating, sense of falling or misplacement of internal organs, nervousness, desire to cry, palpitation, hot flashes, dark rings under the eyes, or a loss of interest in life, write to me today for free trial treatment.

Mrs. M. Summers, Box 309 Windsor, Ont.

CONSTIPATION, LIVER COMPLAINT, BILIOUS SPELLS.

When your liver becomes sluggish and inactive, the bowels become constipated, the tongue becomes coated, the breath bad, the stomach foul and sick, and bilious spells occur on account of the liver holding back the bile which is so essential to promote the movement of the bowels, and the bile gets into the blood, instead of passing through the usual channel.

The only proper way to keep the liver active and working properly is to keep the bowels regular by using Milburn's Laxa-Liver Pills. They work smoothly and gently, and do not gripe, weaken and sicken as so many laxative pills do.

Mr. James P. Colter, Hartford, N.S., writes:—"I have used Milburn's Laxa-Liver Pills for constipation and liver complaint. At one time I used to have a bilious spell every little while and once was in bed for four months. Since taking your pills, the bilious spells have left me. I have recommended Laxa-Liver Pills to many others here, and they are growing in favor every day."

Price 25c. a vial at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

each spoke free. But the flesh swiftly covered this unexpected nakedness by covering the face of each man with a sheepish grin.

"As long as we know how it is, then," said Burton, "let's split the differ'nce. Let's make it sixteen hundred and fifty dollars."

Hellman kicked at the leg of the stove. His small, red-rimmed eyes shot toward his wife resentfully, but she did not see him. She had noticed how the little girl's apron strings hung—one end dragging below the hem of her skirt, as if she had pulled it about in front to tie it—and the woman was kneeling to retie the bow.

"It's an infernal steal," said Hellman, and saw the understanding grin stil on Burton's face, "Done, though," he aded. "Done."

While the men were making a meeting place for the signing of the papers Hellman saw his wife kiss Mary goodnight. It struck him vaguely, and afar off in some sense that she and the child were somehow allied by an obscure instinct, which he, who was one flesh with the woman, and Burton, of whose flesh was the child, were strangers; as if some Eternal Woman in things had abruptly manfested her share in the eternal creation. The impression, coming to him rudely and finding no medium, made him angry. "She's done me out of a hundred and fifty dollars, cool," he sneered to Burton. "And your girl there, she's made you pony out a hundred and fifty more'n I'd 'a' let you have the place for if you'd 'a' hung on."

Burton looked over at the child. "They don't know nothin' about business,' he said, in a great apology.

Hellman threw out his fingerless hand. "Come on—you," he said to his wife. "You can do the scrimping and sagin' to pay for this deal, I can tell you. Mebbe ye'll learn after a while 't 'busines is business.' "

The gaunt woman looked down at the motherless child. "I wish't your mother could come back an' explain it out to 'em," said Hellman's wife, "an' tell 'em whether 'business is business' sounds so almighty grand a sayin' to the dead."

HOUSEHOLD SCIENCE COURSES HAVE PROVED BENEFICIAL

Owing to conditiions resuting from the influenza epidemic the Short Courses in Household Science, held under the auspices of the New Brunswick Women's Institutes, were not opened until Feb. 18. These coruses last for ten days and this year were held in eight different centres throughout the Province, viz., Woodstock, Edmunston, Fredericton, Newcastle, Bathurst, Sussex, St. Stephen, St. John. Classes in cookery, sewing, millinery and nursing were held each day throughout the course. Efficient instructors, specialists in their respective subjects, conducted the classes. Intense interest in the work was shown everywhere throughout the province and a general feeling prevails that much good has been done.

During the last week of March and first week of April we were pleased to have the opportunity of co-operating with the Agricultural Societies in their short course work held in Madawaska and Victoria Counties. One session of each of three short courses held in these counties was given over to the Women's Institute for demonstration and instruction purposes.

Proud are we with the successful results of our co-operative action. Following these short courses an organization campaign was launched in the counties of Madawaska, Restigouche, Gloucester and Kent, resulting in the addition to our organization of eighteen new branche institutes. These branches were established in the French speaking districts, the work being conducted by the French Assistant to the Supervisor of Women's Institutes in New Brunswick.

One short course lasting three days was given to the French speaking members of the instiutes of Madawaska County at Claire. Classes in cookery, management and home nursing were held each day of the course. Similar courses will be held in June and July in the counties of Restigouche, Gloucester and Kent.

Prize winners in Ten Days Short Courses held in Woodstock, Edmundston, Fredericton, Newcastle and Bathurst under the auspices of the New Brunswick Women's Institute.

Carhartt's Overalls

My Price Protects You

YOU may be told that you can buy overalls equal to Carhartt's at a lower price. Believe me, you can't. No one can. The fine quality of Carhartt's and the fair price at which they are sold are due to my enormous output—probably the greatest on the Continent which enables me to do with a slight profit. How then can any manufacturer doing business in a smaller way, with less efficient methods, and with few opportunities of cutting expense, hope to give as much value as Carhartt's for less money. Be assured of this; that if it were possible to offer you the present quality of Carhartt's at a lower price I would be the first to do it.

Names of prize winners for similar courses in Sussex, St. Stephen, St. John will be published in near future.

The summer campaign of 1919 will take the form of demonstration work among all the branch instiutes, the contemplated subject being milk, its composition, food value and practical use in many ways.

According to the branch reports sent in to the Head Office each month, the prevailing work seems to be communiy, school improvement and public improvement work. Some work also is being done in connection with the War Savings and Thrift Stamp campaign—he work of the War Savings Society being incorporated into that of the branch institute.

An invitation from the Federation of Women's Institutes in Canada has been extended to and accepted by the Women's Institutes of Great Britain to form an International Federation of Women's Institutes Mrs. A. T. Watt, the Superintendent of Women's Institutes in England is coming to Canada in the near future to carry out the necessary arrangements and will lecture throughout Canada while here.

Women's Institutes of New Brunswick can you not catch a glimpse of the future? Take new courage, strengthen yourselves, go forward, looking unto the ultimate goal of being partakers in one of the most important businesses of creation—the making of better homes, better citizens, a better world.

SWAT THE FLY

Just listen to this—it is the Fly's Multiplication Table: "May 1st, 1 fly egg hattches on maggot, which becomes a female fly; May 25th, the female fly lays 120 eggs; June 5th, 120 adult flies issue, of which 60 are females; June 19th, the 60 female flies lay 7,200 eggs; July 1st, 7,200 flies are hatched, of which 3,600 are females; July 14th 3,600 female flies lay 432,000 eggs; July 25h, 432,000 female flies issue, of which 216,000 are femaies; Augus 14th, 216,000 female flies lay 25,920,000 eggs; August 24th 25,920,000 flies issue, o, which 12,960,000 are females; September 18th, 12,960,000 lay 1,555,200,000 eggs, which October 4th bring forth 1,555,200,000 flies." SWAT THE FLY.

THE SEASON'S HATS

There is no end to the styles of this season's hats, but just for the present the rather substantial straws in browns, tans, and black with rather a high gloss are more in vogue than they will be later in the season. And these are very simply trimmed with bands and quills, or made ornaments of beads and wool. They are good, serviceable hate for long drives over country roads, and just as suitable for other wear. The shapes are varied. There are the close toques, the always popular tricorns and the large shapes with rolling brims, and there is no doubt but the wide brimmed sun hat will be popular later on. At the present time there is one advantage, women may exercise their own individual taste, wear what is most becom, and be nevertheless, in the style.

STRAY SHRAPNEL

While we're at it, why not make the world safe for baseball fans. Might start by interning the peanut sellers at ball parks, restraining the writing Bullsheviki who make their livings by scribbling baseball stuff and keep knocking the game, and suppressing the pop-eyed fan who busts your straw lid every time some player makes a base-hit.

Capital is an important feature of a poultry business. A man may get up early and work late but if the birds do not receive good feed and live in the right kind of houses the work is apt to be in vain. Feed and houses and good breeding stock mean that capital must be invested in the business and without the cash the poultryman must advance very slowly until it is acuireqd.

PILES Do not suffer another day with Itching, Bleeding, or Protruding Piles. No surgical operation required. Dr. Chase's Ointment will relieve you at once and as certainly cure you. 60c. a box; all dealers, or Edmanson, Bates & Co., Limited, Toronto. Sample box free if you mention this paper and enclose 2c. stamp to pay postage.

126 Months' Wear

Does *your* property go ten years, before repainting? Take a look at the surface today. Three to four years is a pretty fair average life for Paint, though many cases of ten years or more are known where S W P was used.

Weather worn, scarred and peeling surfaces can be saved. Two or three penetrating, healing coats of SWP will put an end to decay, renew the original beauty and distinction of your property, and remain for years a profitable investment. Big Corporations are among the largest users of paints. Paint Protection is as necessary as Fire Insurance. Fire destroys only one building out of a thousand. Weather exposure and decay attack the other 999, unless the SURFACE has been protected by paint. Fire begins at the surface—so does decay, rust, and wear. "Save the Surface and you save all" is an apt expression, full of significance for every person who has money invested in property.

SAVING STEPS.—AIDS FOR THE ALWAYS-BUSY HOUSEWIFE

Do you do your own work? Then the most important problem for you is how to "make your head save your heels."

Begin with the kitchen, for it is probable that you spend more of your waking hours there than in any other room in the house. It is your office—your place of business. Three times three hundred and sixty-five meals a year have to be cooked and served from it, and perhaps all of them by the labor of your own hands. The sum total of that drudgery looks stupendous, but you can lighten it greatly and really add pleasure to much of it, if you put your intelligent interest into it. That new science of efficiency about which we hear so much in every business is nothing more than you can apply right at home—the conservation of time and strength.

Water! Drainage! Ice!

The first consideration is water; then drainage; then ice. Get at any cost; you can possibly afford pure water piped into your kitchen, and a good tight drain to carry off the waste slops. If you can't get the water brought in, at least insist on the drain and kitchen sink to carry it out. The expense of this convenience is so slight that no woman should be without it. Twenty-five feet of vitrified tile can be bought for one dollar and seventy-five cents; an iron sink costs not more than a dollar and twenty-five cents, and the pipe and trap connection need not bring it up more than a dollar. For five dollars a farm or village house should procure a waste water connection for its kitchen. If you can't get a cess-pool built to drain it into, let the waste water drain down an incline to a sunken barrel in the garden, where with rain water from the eaves you will have a fine liquid fertilizer for your vegetables.

Those Fatal Cellar Steps

The great advantage of ice in the lightening of the kitchen work is in the keeping of the food without those wearying journeys to and from the cellar. Often the cellar is not conveniently located, nor are cellar stairs easy. If you ca managine ice, why not make your own ice box? A wooden box lined with zinc or tin, or even oilcloth, with a hole bored in the bottom for the escape of water, is all that is necessary. Put shelves made of slate across the sides or ends, leaving a space in the center for the ice. Now build around this box another large enough to leave an intervening space for a layer of some non-conducting material such as charcoal or sawdust or fine-cut hay. When it is ready for use put it in a cool, handy place; but KEEP IT OUT O FTHE CELLAR. It may save a little ice to keep the refrigerator in the cellar, but it certainly does not save legs and backs.

When the cool weather comes and ice is no longer necessary a window-box for food is a great convenience and another avoidance of those fatal cellar-steps. A window in pantry dining-room or kitchen can be appropriated to its use.

Of course, where a supply of garden stuff, roots and meats must be cared for, the use of a good cellar is imperactive, and such a mine of supplies should receive the housewife's most careful attention, but she should get the morning allowance out of it and then have done with the cellar for the rest of the day if possible, except on cleaning days.

Is your kitchen the right size? Take courage is it seems too small, for much can be done to make it a time-saver; but if it is large, set to work at once to rearrange it, for it is your real woman-killer.

A good modern kitchen need not be more than twelve feet square, unless the family to be provided for is very large and needs to have several people working in it at once. But if you already have a large one, it is possible t osave steps by having the stove, sink, work tables, cupboards and utensils grouped together and as near as possible to the entrance to dining room and pantry. The remaining space may be devoted to laundry work or other duties not in the daily routine. In farm life this end of the kitchen can be well used as a sitting-room for the men.

Your tools must be considered next. Get rid of the tables with wooden tops to be scrubbed. Cover with zinc the one on which the hardest and dirtiest work is done; or, if you can find one, get an old marble top from some discarded table. For the ones used least of all, buy white oilcloth covers, costing half a dollar for a two-yard squrae.

Have a gas or oil stove. They save fuel and no end of work in quick-heating jobs. Get a high stool or put longer legs on a chair; and then sit on it for every kind of work you can possibly do sitting. Think it a discreditable stupidity to iron or to peel anything on your feet!

Up-to-Date Devices

Look into every labor-saving device you hear of, and try it out if it is within your means to buy. Don't let the men of the family outdo you in their intelligent application of new machinery to business. Every woman can have a fireless cooker, thereby saving hours of fussing over the hot stove. Use a bread machine if you can afford it, and every department store now sells some sort of a simple hand vacuum washer under two dollars, a wonderful labor-saver. Hotels are on the constant lookout for labor-savers as an economy; so should you be.

Light-weight cooking utensils, a good raisin-seeder, a lemon-squeezer, a wire dish cloth for cleaning the pots, a flexible palette knife, a dish-

I KNOW A WOMAN'S SUFFERINGS

I am a woman.

What I have suffered is a far better guide than any MAN'S experience gained second-hand.

I know your need for sympathy and health.

And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.

Are you unhappy, unfit for your duties? Write and tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.

If you suffer from pain in the head, back, or bowels, feeling of weight aud dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creeping feeling up the spine, palpitation, hot flashes, weariness, sallow complexion, with dark circles under the eyes, pain in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your own home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

MRS. M. SUMMERS, Box 309

Read My FREE Offer:

To Mothers of Daughters. I will explain a simple home treatment which speedily and effectually dispels green-sickness (chlorosis), irregularities, headaches and lassitude in young women, and restores them to plumpness and health. Tell me if you are worried about your daughter. Remember it costs you nothing to give my method of home treatment a complete ten days' trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. Is health worth asking for? Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your feelings, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

Windsor, Ontario

washer, small water motor that can be applied to the washing machine or the churn—all of these things, as fast as they can be afforded or intelligently applied, save time and steps and so human life.

Never Two Steps Where One Will Do

If you don't get away from the necessity of keeping things in the cellar a dumb waiter that lets down through a trap door in the floor is a simple thing to install and a very great convenience. Have a large tray on which to remove the dishes from the table to t ehpantry or sink. Keep a pail, closely covered, in the kitchen ofr refsue—don't run out every meal with your scrapings. Have a place for everything and insist on everything being put in its own place. Have a place where any member of the family can find strings, tacks, anils, hammer, scissors, wraping paper, and then expect the user to put them back when used.

Keep your heavy utensils that are seldom used, in your enclosed cupboard and hang all your things for daily needs in plain sight; and so near to the place where they are wanted that you can reach out and take each off its proper hook without walking any distance to get it.

And if you will make a vow never to take two steps in housework where one can be made to do, you will be astonished at the result in a short time. Once put your feminine wits to work at it and the most astonishing contrivances will spring into being.

LET CHILDREN HELP

I yield to no one in detestation of child labor. I believe that any nation which allows its young to slave in mines or factories or stores is hopelessly mortgaging its future. But I also believe that it is almost as bad to deny children all opportunity for usefulness.

Which is what many parents nowadays do.

They permit their little ones to spend their time in undirected play. They do not dream of letting them help in any little job about the home.

They even perform for the children tasks—washing them, dressing them, etc.—which the children at an early age should be tought to perform for themselves.

As a result their children are unfavorably, sometimes disastrously, affected in many respects.

They tend to grow up selfish and lazy. The instinct of altruism, of service for the good of others, becomes shrivelled in them.

Vain and conceited, they crave a domineering leadership over all with whom they later associate. When leadership is denied them, as it usually is, they are bitter, resentful and unhappy.

In extreme cases they may become nervously overwrought in consequence of their failure to associate smoothly with their fellow beings. Many a nervous invalid may justly attribute his or her ills to parents who unwisely pampered.

For all of which reasons, while I oppose child labor as that term is commonly understood, I do not think that some work in the home, of a character suited to the strength of the child, is beneficial rather than hurtful—is indeed esential to a child's best development.

There are numerous ways in which little boys and girls can help their mother in the home. And it is worth observing that, as a rule, children are at first eager to help.

To be really helpful they, of course, need training. Too many parents are inclined to think that this is more trouble than it is worth. But they should look at the future as well as the present.

Let them encourage, not chill, their children's ardor for service. Let them foster, not deaden, the natural tendency of self-expressing endeavor.

Then we shall have fewer idlers and incompetents in adult life, fewer men who habitually shirk work, fewer women of really inadequate existence. There is point to a recent writer's declaration:

"The tragedy of the home where the bride knows little about the real keeping of a home can often be traced back to th emother. Of course, mothers could do it better and more quickly, but little hands can learn only through practice.

"Our girls will make far more efficient, happy home makers if the training toward it is begun early in their lives, when they learn to be 'mothers' as well as 'mother's helpers.' "

A Mother's Tribute

THIS letter from Mrs. Roberts gives such a fine idea of the value of Dr. Chase's medicines for use in the home that we shall publish it without further comment.

Mrs. Everett Roberts, 44 Endicott Ave., Halifax, N.S., writes :

"I feel it a pleasure as well as my duty to recommend Dr. Chase's Nerve Food and Ointment. After the shock of the Halifax explosion my system was all run down, and I was so weak that I could not walk. Night after night I lay awake unable to sleep. Nothing did me any good until one of my neighbors recommended Dr. Chase's Nerve Food. After a treatment of this medicine I can positively say that my health and strength have been restored, and I can now sleep well and do my work as well as ever.

"I used Dr. Chase's Ointment for my baby, who had ringworms all over his face. I tried almost everything I knew of without success until I used Dr. Chase's Ointment. This cured him in a short time. I would not be without either of these medicines in the house, and trust this may induce others to give them a trial and be convinced of their merits."

You can scarcely ask for a stronger gurantee of the value of a medicine than the portrait and signature of A. W. Chase, M.D., on the box. This is for your protection against imitations and substitutes. Edmanson, Bates & Co., Ltd., Toronto.

Minard's Liniment Co., Ltd.

Gents,—I have eused your MINARD'S LINIMENT in my family and also in my stables for years and consider it the best medicine obtainable.

HINTS FOR MOTORISTS

by ALBERT L. CLOUGH

Editor Motor Service Bureau Review of Reviews...

THE MOTOR DOCTOR'S "FAVORITE PRESCRIPTION." — GRINDING VALVES IS GOOD FOR JUST THE ONE THING— LEAKY VALVES

When the seats and stem guides of engine valves are so badly designed that they are not adequately cooled by the circulating water, the valves themselves, especially the exhausts, may become so hot as to warp, or to form scale or pits in their surfaces. If the valve material is poor this effect is intensified. An undue amount of oil vapor and gasoline soot in the mixture fouls the faces of the exhaust valves especially and the constant hammering of valves on their seats with road dirt brought in with the mixture as an abrasive, produces its effect in time. However, the valves of modern engines are well cooled and of good material, and it is rarely that a set of them requires any attention for several thousand miles. Oftentimes a mileage of five figures is made with no valve grinding being necessitated. Somehow or other, valve grinding has become the "favorite prescription" of the motor car doctor, supposed to cure the engine of "what ails it." It is receommended for all "skips," "knocks," and other infirmities of the ignition and carburation system and for almost everything else, short of broken crank shafts. This is all very foolish. Valves do require grinding at long intervals. They require grinding when they have become leaky and under no other conditions. The wise motorist will disregard superficial advice and not waste time and money grinding well seated valves, to cure troubles which are due to entirely different causes.

PECULIAR ANTI-FREEZE LIQUID

A. C. asks: What can you say about using a mixture of kerosene and water in the radiator during cold weather?

Answer: It seems as if this must be a joke, because kerosene and water do not mix. If they are put into a cooling system, at the same time, the kerosene floats upon it. The water is just as likely to freeze as though there were no kerosene near it. Kerosene alone is sometimes used s a non-freeze liquid, but the ombination which you suggest is not worth considering.

TESTING SPARK PLUGS

J. A. M. writes: I test each of the spark-plugs of my engine, by removing it from its cylinder, laying it on the engine, with the cable connected to it and running the engine on the other five cylinders. Should the plug being tested give a steady stream of fire or should it come and go? Is it true that a plug may act all right when tested in this manner and still fail to work properly when under compression?

Answer: The spark at the plug under test should be perfectly regular, not intermittent and, if the engine is running at good speed, it should appear continuous. At low speed, each separate spark can be distinguished.

When tested in the open air, a plug with a cracked porcelain or dirty insulating surfaces may spark perfectly, but when under compression, the electrical discharge may pass through the crack in the core or over the surface of the porcelain and no spark occur between the points.

GETTING THE LAST WEAR FROM OLD CASINGS

Lengthening the Tire's Road to the Scrap Heap

Considering the high tire prices prevailing, it is natural that one should seek to prolong the usefulness of ever casing and run it out to the bitter end—the moment of final, irreparable blowing out. When there s reason to believe that, through age or long service, the fabrc of a certain casing has become dangerously weak, it is a very common practice to reinforce the deteriorated materials by placing a reliner inside it. Sometimes the weak spots are localized and then inside blow out patches (which can be made from discarded casing, as a matter of economy), are inserted to reinforce them, instead of complete reliners. In the case of a shoe, the tread of which has come off or been worn out in spots, the fabric at these portions will soon wear through in service and a blow out will occur. Sometimes it may be worth while to apply a laced on outside protector or blow out patch over a treadless portion of the casing, if this is not too large, but if the tread is pretty generaly gone, there is not much to be done, except to let the fabric stand road wear as long as it will and scrap the casing when it blows out. Retreading of old tires is unprofitable and in fact it is seldom, if ever, advised except in the case of an almost new shoe, the thread of which has been injured by wheel misalignment or excessive slipping due to obnormal brake applications. When an old casing is being run to destruction, to get from it what little remaining service it has to give, the inner tube used in it should be anl old one of little value, as the blowing out of the casing will involve the tube in disaster. Fresh, new tubes, seem to tear worse under such circumstances than old, inferior tubes which give out with less extensive injuries. When one is wearing out old tires, is the time of the most vital importance. With all new tires on the wheels, spare rims and casings are seldom called for, but when getting the last wear out of old shoes, the single spare rim and tire, customarily carried, may well be reinfoced by an extra, space casing.

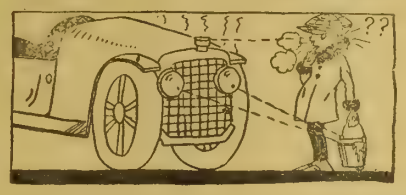
much should be put in during severe weather?

Answer: An engine designed to be water cooled (as most engines are), requires that the radiator, the cylinder jackets and piping should always contain enough liquid to circulate freely. Unless this is the case, heat produced in the cylinder walls, by the explosions, will accumulate, instead of



being taken away by the water, until the cylinders are too hot to operate safely. The cylinder walls, not being exposed to the outside air, it makes no appreciable difference how cold this is. An engine designed to be cooled by air, has means by which air is rapidly circulated around its cylinder walls, just as the cylinders of a water-cooled engine are kept surrounded with moving water. It is best to keep the radiator nearly full, in warm and cold weather alike.

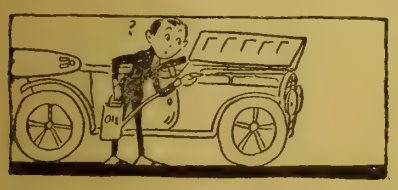
CARE IN USING THE STRANGLER

The very low volatility of commercial gasoline has made it necessary that every car be equipped with a "choker" or "strangler," acting to close the carburetor air-intake and send a great excess of gasoline into the cylinders, in order that enough of the lighter fuel constituents may enter to vaporize and cause an explosion, when the cylinders are not warm. Usually this choker is closed and opened from the operator's position and, as fuel is now, it has to be operated every time the engine is started from an unwarmed condition, practically the year around. The operator closes the shutter at starting, but too often forgets to open it soon enough, not realizing the immense waste of fuel and the serious effect upon the engine oil thus caused. It is extremely important that the choker be opened as much and just as soon as practicable, to avoid useless waste. As soon as the clutch is engaged and the car moving, it should be opened to see if the engine will not then continue to run and it should be closed only when necessary, as in acceleration, or when a considerable throttle opening has to be made use of. For a little time after starting a car cold, the choker may have to be opplied repeatedly, but it should be kept in action as little as practicable, if the operator has any regard for fuel economy or conservation of engine oil.

ABOUT OILING VALVES

P. G. H. asks: Should the valves of an engine be oiled?

Answer: It would perhaps be a good thing if valves could be oiled slightly. The exhaust valves of many engines receive at least all the oil that is good for them, but some motorists put a little ehigh-test oil in the gasoline to oil the inlet valves and the upper parts of the pistons, but this is seldom done. Valve stems should be kept oiled to reduce the rate at



which they wear in their guides. Where the valve mechanism is fully enclosed and a little oil spray is allowed to enter the enclosure from the crank case, valve stems and all parts of the valve gear receive pretty good lubrication, but in the case of exposed valve gears, even though oil is squirted onto the stems from a can, it soon escapes and the valves operate dry. All rocner arms and push-rod ends require frequent oiling.

COOLING SYSTEM QUERY

J. A. M. asks: In very severe cold weather, it is necessary to keeep any liquid in the radiator or will the extreme coldness of the air act as a cooling agent? Perhaps an engine has to be specially constructed in order to be kept from overheating in this way. In case water must always be kept in the radiator, how much should be put in during severe weather?

Answer: An engine designed to be water cooled (as most engines are), requires that the radiator, the cylinder jackets and piping should always contain enough liquid to circulate freely. Unless this is the case, heat produced in the cylinder walls, by the explosions, will accumulate, instead of being taken away by the water, until the cylinders are too hot to operate safely. The cylinder walls, not being exposed to the outside air, it makes no appreciable difference how cold this is. An engine designed to be cooled by air, has means by which air is rapidly circulated around its cylinder walls, just as the cylinders of a water-cooled engine are kept surrounded with moving water. It is best to keep the radiator nearly full, in warm and cold weather alike.

AUTO TIRES FOR FARMER SUBSCRIBERS

We Can Supply All Sizes Promptly. If You Are a Subscriber for the Maritime Farmer, Yours is the Privilege

The Maritime Farmer is pleased to announce that it can supply automobile tires in all sizes to bona fide subscribers of the Maritime Farmer. We are prepared to save our subscribers a good many dollars. We can also supply inner tubes for any size tire. The goods supplied by us are all FIRST QUALITY and are fully guaranteed. If you want to avail yourself of our auto tire service send along the size of your tire and we will quote you.

TO IMPROVE RIDING QUALITIES

R. G. writes: I own a high grade car, built four years ago, of a make which has now been discontinued. It is in splendid condition and satisfactory in every way, except that it rides frightfully hard, save when carrying seven passengers and even then it is pretty stiff What do you suggest?

Make your Ford Transportation even more Economical.

BRIGHT OUTLOOK OVERSEAS FOR CANADA'S POULTRY INDUSTRY

"The market for Canadian eggs in Great Britain and France is exceedingly bright," said W. A. Brown, B.S.A., chief of the poultry division of the Federal Live Stock Branch on his return from Europe, where he went a short time ago for the express purpose of investigating and obtaining first hand information regarding the egg and poultdy situation and the possibilities of extending Canadian trade in that direction. Needless to say, Mr. Brown obtained what he was after, and after a most searching investigation, which covered practically every phase of the trade in Great Britain and France, he has returned to Canada with a most encouraging message to Canadian poultrymen, the assurance of a good market for their produce for many years to come. His investigation included a personal visit to all the large egg dealers in Great Britain with the exception of those in the cities of Hull and Newcastle, and on the continent he went right up to within a mile or so of what is known as "no man's land."

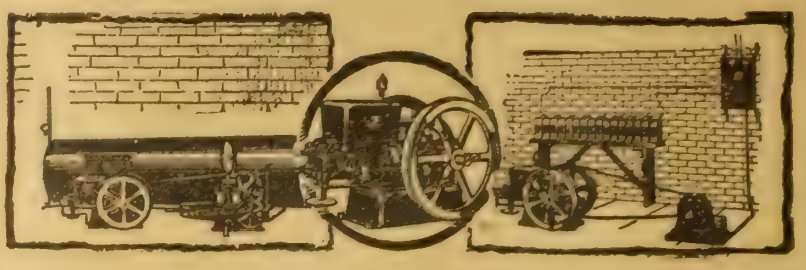
In France Mr. Brown found eggs as well as other comomdities very scarce the former selling at 95c to $1.00 per dozen, and even at that they could not be obtained. The people were anxious to buy eggs of ahy kind, preferably Canadian produce; but the great difficulty was the inadequate shipping facilities. A few Canadian eggs had reached France indirectly, but a shipload was now on the way over. Mr. Brown, however, pointed out that the demand for eggs might not continue for very long because France would be producing enough for her own use at least before many years. It was surprising to find how wel the flocks of that country had been kept up even to within a few miles of the firing line, and although smaller than formerly the French farmers have a nucleus, and it will only be a matter of time before they recuperate sufficient to relieve the situation.

In the British Isles, Mr. Brown found the same scarcity of eggs, but with a situation somewhat different to that of France, as there was not the same prospect of Great Britain ever being able to supply her home demand, with the result that she would have to rely upon importing a large percentage of her requirements. At present that was not possible, owing to shipping difficulties, and eggs were selilng at about 80 cents per doz. "Here is Canada's opportunity," said Mr. Brown, "and there is no reason why we cannot capture and hold a great part of that trade if we go after it as we have the advantage of shipping and can supply the quality if a little more care is exercised." Of course competition would be keen, no doubt, but Mr. .Brown felt thta could be overcome.

In regrd to the disorganized condition of Russia her egg producing area was far inland, consequently she was up against the shipping question. Here China was the only real competitor, and Mr. Brown felt that this competition might be serious as great quantities of Chinese eggs were reaching Europe today, and they were also sending in an egg powder which was bound to have a tremendous influence, as it fas becoming popular, largely on acocunt of its easy shipment.

Asked as how Canadian eggs compared in quality with other countries, Mr. Brown explainer they could hardly compare with Danish and Irish eggs but were a close second. The finest eggs Mr. Brown saw were on the Preston Market in England, near where the great poultryman, Barron, carries on his well-known breeding establishement. The country round about has become thoroughly infested with his strains and the result has been a great improvement in the eggs marketed. However, Mr. Brown explained that all the British eggs were not up to such a high standard and next to the Preston eggs the Danish products were the best. They were remarkably uniform, clear, large, but somewhat transparent, and gave the appearance of being short keepers. In that respect they were inferior to the Canadian egs and could not stand shipping as well. The Irish eggs were almost as choice as the Danish but even with these two countries shipping the supply was far short. Next to these came the Canadian eggs and Mr. Brown had some interesting conversations with the Old Country dealers. He explained to them our system of grading and how our Westenr Provinces were going into poultry raising and actually exporting eggs. He assured them that Canada's effort towards increased production was not a spasmodic affair brought on by the war, but would continue to grow as time went on. He said the dealers over there were very glad to hear that, and they appeared anxious to get the Canadian product, in fact, are getting some of it now.

"On the other hand, al is not going to be plain sailing," continued Mr. Brown, "and Canadians must improve the quality of their product if they wish to capture that great market." This could only be done, he pointed out, by getting eggs onto the market in les time than is customary at present. He contrasted the slow, careles methods of handling perishable products in Canada with the rapid transit carried on in the British Isles. Yet he wa was glad to know that a great improvement was being effected in this country by the local eggs cir-



Complete The Farm Home With This Equipment

Running water and electric light are all that are necessary to make the modern farm home as comfortable and convenient as the city house. Insure this comfort in your home by installing a

Fairbanks-Morse

Pneumatic Water System and Type "F" Electric Light System

This combination brings the farm up to date and guarantees comfort, economy and efficiency. The same engine runs them both. It means light anywhere you want it—running water in any part of the buildings. It means the drudgery removed from the ordinary chores and the house work.

St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, Windsor.

cles where they were in operation.

In conclusion Mr. Brown said that he had no additional recommendations to add to those adopted at the recent poultry conference held at Ottawa, but wolud like to emphasize a few of them, particularly the ones dealing with increased and economic production, co-operative marketing, standardized product and quicker transportation.

CHICKS KEPT WARM LOSE POWER OF LEGS

I have some chickens two weeks old, hatched in an incubator. They have done well all along until now. A number of them are losing the power of their legs. I have kept them in the brooder, and in warm condition acocrding to directions with the incubator.—J. S. P.

A number of queries reach this office regarding the troubles that afflict the young chicks after they leave the incubator, showing that many baby chicks are lost because of wrong methods and feeding. You have kept your chickens too warm, without exercise, and it is not at all likely that you can bring those that have lost the power of their legs, back to normal again.

All brooders should have a partition in the centre with a runway for the chicks to go from one room to the other and a swinging door for the attendant. The stove is placed on one side of the partition and the cool room is used for feeding and exercise. It is necessary to have a cool room so the chicks can get away from the heat. This is one of the secrets of sucecssful brooding. It also pays to give the little fellows access to the ground as soon after starting to brood them as possible. Even the second and third day is none too early, care being taken the first few days to be certain they know the way into and out of their house. Provided the sun is shining and no hard winds can hit them, baby chicks do well if allowed to run in and out even on fairly cold days. Do not put them out on hard, frozen ground.

The houses for these brooder stoves are built similar to laying or breeding houses. Special care must be taken to insure proper house ventilation. A slow movement of fresh air coming in on one side a foot above the floor and raising gradually upward as it warms and the oxygen from it has been consumed, until it reaches a point close to the ceiling where there should be an exit opening, will help keep the house free from impurities and foul odors, thus maintaining health, vigor and appetite among the chicks.

To make the house comfortable provide some method of ventilation near the floor but avoid drafts. Be certain to provide for one cool room. You want light in your brooder house but not in the direct rays of the sun. Keep the chicks busy and active. Put fresh earth on the floor in one corner of the room every two or three days. This will help prevent foot and leg weakness besides the little fellows like it. Grind some lean meat and mix equal parts of bran, shorts, and ground meat, with a little water just to moisten it a trifle. After it is mixed run it through a sausage mill or meat grinder and then feed it to the chicks every day.

Cover the floor of the brooder rooms with clover or alfalfa chaff or fine cut straw. Don't have this too deep. Keep sour milk or butter milk before them to drink at all times from the first day. For the first two or three days feed a mixture of two-thirds rolled oats, one-third wheat bran, mixed with hard boiled eggs, a little powdered charcoal and fine bone meal. Feed a little five times a day for the first three days. Then give two meals a day of commercial chick feed. The first mixture is fed morning, noon and night and the chick feed is given between meals. As they become older, gradually eliminate the rolled oats

No less inside the house than out, every surface calls for protection. Daily use means daily wear upon the surface of everything used. Appreciate the principle of surface protection.

Agricultural machinery has to stand severe exposure. Their surface protection is absolutely indispensable if rust and corrosion are to be kept at bay. Rust cannot penetrate till the surface is broken. Save the surface and you save all.

Anything worth owning is worth preserving

GOOD money put into a home, a barn, a silo, or automobile needs protection as much as good money put into a bank

A wooden house is a wonderfully enduring thing if given reasonable protection. What is true of wooden houses is true of all things made of wood, be they in the city or country, be they stable or garage, wagon or desk.

And what is true of wood is true of other materials. Steel and iron from bridge and skyscraper to roof of shed—they last or they rust, depending upon whether or not they have surface protection.

If protected the surface is an impassable barrier to rust, rot, friction or disintegration. If unprotected it is an open door.

Whatever other good purpose paint and varnish may serve, in every case they save the service—their first and greatest service to property.

Your property is safe only when the surface is safe. The chief purpose of all paint and varnish is to save the surface so save all.

THIS ANNOUNCEMENT *is issued by the Canadian Save the Surface Campaign Committee, for the purpose of educating the public in the Preservative and Protective value of Paint, Varnish and Allied Products for the Conservation of Property, and has received the approval of the Canadian Trade Commission in the following words:*

"The realization of the above objects will lead to employment during the Reconstruction Period and bears our entire approval.

THE CANADIAN TRADE COMMISSION

Commissioner."

13

"SAVE THE SURFACE AND YOU SAVE ALL" *Paint & Varnish*

WOOD | PLASTER | CONCRETE | MANUFACTURED PRODUCTS | METAL | BRICK

until you use only the chick feed and keep before them a dry mash mixed in the following proportions: Ten pounds wheat bran, two and one-half pounds ground oats, five pounds sohrts, two ounces fine salt. If you cannot secure sour milk or butter milk then mix two pounds of dry beef scraps with the above. If you use any form of milk, keep it before them at al times or at least the first half of the day. Use clippings from sprouted oats or cut up some onions or lettuce occasionally.

THE USE OF DISINFECTANTS TO DESTROY DISEASE GERMS ESSENTIAL ON EVERY FARM

(Continued from page 604)

Cresol

Cresol, commonly termed "straw-colored carbolic acid," liquid "carbolic acid," etc., in a 2 per cent. solution is an efficient disinfectant. It has the disadvantage, however, of being somewhat difficult to dissolve, so in preparing a disinfecting solution warm water should be used and care exercised that the drug is entirely dissolved. As the disinfecting power of cresol is dependent upon the amount of cresylic acid contained therein, it is essential when using the drug to know the degree of purity. Grades can be purcahsed under a guaranty to contain from 90 to 98 per cent. of cresylic acid. Any containing less than 90 per cent. should be rejected.

Compound Solution of Cresol

Compound solution of cresol (liquor cresolis compositus) is composed of equal parts of cresol (U. S. P.) and linseed oil-potash soap. It is an efficient disinfectant in a 4 per cent. solution and has the advantage of mixing readily with water.

Zenoleum is also a very efficient disinfectant and should be used more widely on most farms.

SOME GENERAL INFORMATION ON LIME AND ITS USES AND FUNCTIONS IN SOILS

(Continued from page 905)

Limestone or marl may be added immediately before seeding or to growing crops without injury, but if caustic lime is used, it should be applied and incorporated with the soil at least ten days or two weeks before seeding, in order that its caustic properties may be dissipated before the seeds germinate, thus avoiding injury to the young plants.

Alfalfa may be top-dressed with the carbonate carrying compounds and where the alfalfa renovator or springtooth harrow is used the lime may be mixed with the soil to some extent. As a rule if the land is limed previous to this crop it will endure as long as the alfalfa is permitted to occupy the land. Reports are on record which show that permanent meadows and pastures growing on soils deficient in lime may be profitably top-dressed with this substance.

It is readily seen that one may apply lime under widely different conditions. Thus, there are opportunities for the consideration of this operation in relation to other farm work, condition of weather and the land.

Lime must be applied repeatedly to the soil. It has been shown by determining the amount of lime carried by river water, well water, and drainage water from tile, and large containers filled with soil and placed in the ground, that as a general rule much more of this substance is washed out of the soil than is removed by crops. Although the amount so lost has been shown to vary rather widely it is probable that 300 pounds per acre annually, closely approximates the losses under average conditions. At any rate it is now looked upon as being sound practice to lime the soil at least once in each four or five-year rotation. Further experience may show that small frequent applications of lime are most profitable on some soils.

Plows Fast - and Plows Well

RIGHT NOW is the time to get a lot of profitable plowing done. Right now is the time to lay the foundation for a bumper crop next year.

Plow fast — and plow well.

Plow with a Cletrac tank-type Tractor.

10 acres a day — plowed deep and well pulverized. Plowed economically because the Cletrac tank-type Tractor absolutely operates on kerosene (coal oil)— uses no more kerosene than other tractors use gasoline. Intake completely covered by burning hot exhaust — vaporizes kerosene entirely—that's the secret.

The Cletrac tank-type Tractor will do the work of three teams and three men in plowing and summer fallowing. Saves time.

Puts more ground under cultivation—*earlier*.

Get that waste land to work, too. The track-laying Cletrac is the right tractor for work over rough ground. Climbs hillsides where horses can't pull a plow. Plows heavy muck land and soft ground *where other tractors stall*. The Cletrac lays a broad, safe, light track for itself.

Every month in the year you'll find profitable uses for your Cletrac. Small, light, *travelling over plowed ground without packing it*, operating on kerosene— the Cletrac is the tractor of greatest usefulness— 12 h.p. on the draw-bar, 20 h.p. on the belt pulley.

Learn more about the Cletrac tank-type Tractor. Phone or write the Cletrac dealer near you. Write us for our book "Our Owners Say" showing the Cletrac helping other farmers make money.

Ontario Experimental Farm, Ottawa, Ont.

Gentlemen,—I take pleasure in stating that the work done by you with the Cletrac Tractor recently, on the Experimental Farm, Ottawa, was entirely satisfactory either on plowing, discing or on belt work.

I might put particular emphasis on the satisfaction it gave in driving a No. 3 Massey Harris Blizzard Blower in filling one of our Silos; the power delivered was very even and the motor handled the work apparently with very little effort. (*Signed*) *D. D. GRAY, Farm Superintendent.*

Lime and Manure. Under some conditions lime and manure may be applied to the soil at the same time. Where the lime is in the form of the carbonate, namely, as marl, ground limestone, air slaked, sugar factory lime or that obtained from the manufacture of acetone, it may be mixed with the manure in the heap or stable or applied to the soil with it. In the light of our present knowledge the oxide and the hydrated lime should not come in contact with the manure and should precede its application to the soil ten days or two weeks.

Summary.

Lime is needed by many soils to increase their crop-producing power. When applied to soils that are deficient in it lime may alter the structure, neutralize acids and other injurious substances, satisfy the silicates, in some cases make available mineral plant food elements, increase the rate of decay of vegetable matter, make manures and fertilizers more efficient and supply lime needed in the formation of plant food.

The immediate efficiency of limestone depends in a large measure upon the fineness of the particles and thorough incorporation with the soil while that of marl depends upon its purity as well as thorough mixing with the soil. Hydrated lime usually acts quickly in the soil. On account of its greater solubility its incorporation with the soil mass is not so essential, as it tends to move about in the soil with the soil moisture. Especially is this the case with sandy soils and with the larger applications.

Although crops differ somewhat with respect to their lime requirements, it has been conclusively proved that if the soil is deficient in lime the common crops with few exceptions, respond to its use.

The margin of profit from normal applications of lime on so-called acid soils is safe, as has been demonstrated by many experiment station workers and farmers.

The efficiency of stable manures and fertilizers is increased by ample quantities of lime in the soil, conversely, stable manure and fertilizers increase that of lime.

The most economical or best amount of lime to apply to a given soil cannot be determined by laboratory methods, although its needs may be indicated by several. Field trials should always be conducted when one applies lime to the soil, this being nothing short of sound business methods.

Lime should be applied to the soil in the rotation as near as practicable to the crops that are most benefited by it especially if small applications are made. This coupled with the fact that thorough mixing with the soil is essential are the chief considerations in the applications of lime to the soil. In some cases it is profitable to top dress alfalfa. Moreover, permanent meadows and pastures growing on soils deficient in lime may be top dressed to advantage.

Conclusion.

In view of the low lime content of many soils the losses entailed by leaching and by crops removed from the land and much evidence that its use is profitable, every farmer should satisfy himself by thorough field trials that his soil does or does not need this substance. There are many indications that lime, by establishing alfalfa and clover, as well as by its favorable effect on other crops is the most promising single substance the farmer has at his disposal for soil improvement.

Although many facts have been established concerning the liming of soils it is unquestionably true that our knowledge of several phases is meagre, especially is this true of sandy and muck soils. The question as to the most economical fineness of grinding limestone is one that cannot be satisfactorily answered. Moreover, the forms, fineness and size of applications for different soil classes are worthy of serious consideration.

Finally, lime should be looked upon as only one of the conditions involved in permanent systems of soil fertility. Since its presence in the soil results in a somewhat more rapid decay of vegetable matter precautions must be taken by means of crop rotation, turning under crop residues and manure to maintain this substance which is so vital to soil productivity.

LOSSES FROM TUBERCULOSIS

In the year 1916 o total of 3,000 carloads of hogs and cattle were condemned as being unfit for human food by the U. S .Bureau of Animal Industry on acount of tuberculosis. This is a large toll and it is borne very largely by the producer of cattle and hogs. It emphasizes the importance of some money being spent to eliminate the losses from tuberculosis.

MARKETS.

CHARLOTTETOWN

MARKET REPORT

June 2, 1919.

Beef, Ox, 22c to 24c; Cow, 20c to 22c (carcass).
Veal, carcass, 14c to 16c.
Lamb, none.
Mutton, 20c to 22c, carcass.
Beef Hides, 17c per lb.
Sheep Skins, $3.00.
Calf Skins, 35c lb.
Potatoes, market quiet, 80c to $1.00 per bushel.
Carrots, none.
Turnips, none.
Parsnips, none.
Oats, market tsrong, 80c to 85c per bushel.
Cornmeal, market strong, $4.00 to $4.50 per bag.
Bran, scarce. $2.35 to $2.45 per bag.
Oatmeal, $6.00 per bag.
Middlings, $2.50 to $2.55 per bag.
Cotton Seed Meal, none.
Oil Cake, $3.50 to $3.75 per bag.
Buckwheat, none.
Ontario Flour, $12.00 to $12.25 in wood.
Manitoba Flour, $12.25 to $12.50 in wood.
Chickens, none.
Fowl, none.
Turkeys, none.
Geese, none.
Butter, Creamery, 58c to 60c.
Butter, Dairy, 50c to 52c.
Cheese, none.
Eggs, 46c to 48c.
Hay, $28 to $30.00 per ton.
Straw, $12 to $14.00 per ton.

THE CATTLE MARKET

Montreal, June 9.—The second shipment of live stock from the port of Montreal for the season 1919, was made last week on the S.S. Bildster for Havre. This shipment consisted of 325 head of extra choice Ontario steers, which cost $14.75 to $17 per 100 lbs. in Toronto consequently with the ocean freight rate and other charges added, they will be very dear cattle landed in France. The total shipments so far this season have been 554 head.

At the Canadian Pacific Live Stock Market today the offerings amounted to 150 cattle, 150 sheep and lambs, 650 hogs and 1,800 calves. In sympathy with the weaker feeling in cattle at other Canadian centres of late an easier undertone prevailed in the local market today, but on account of the small offerings and the demand being ample to absorb them there was no actual change in prices to note. The best steers on the market sold at $13.50 to $14, and the lower grades from that down to $10, while the best cows and bulls brought $11 to $11.50, and the commoner stock from $7 to $10 per 100 lbs.

The feature of the small meat trade was the strength in calves and prices scored an advance of $1 to $2 per 100 lbs. The demand was good for supplies and an active trade was done with sales of good to choice lots at $12 to $15 per 100 lbs. and the lower grades at $10. The tone of the market for hogs was easier and prices declined 50c per 100 lbs. owing to the drop of $1 in the Toronto market on Tuesday, and sales of selected lots were made here today at $21.50 to $22 per 100 lbs., weighed off cars, and rough stock sold as low as $21. The demand for spring lambs was steady and prices were unchanged at from $7 to $12 each, as to size and quality.

DAIRY PRODUCE TRADE

Montreal, June 9.—The receipts of butter today were 481 packages, as compared with 633 for the same day last week, and 68 for the corresponding date a year ago. The market today was without any special feature to note, the feeling being steady, with supplies more than ample to meet all immediate requirements. There is little or no demand from outside buyers at present, and business in this direction is limited, but there was some demand from local operators, and sales of several fair-sized lots of finest creamery were made at 54½s to 55c per lb. A good steady trade was reported in a jobbing way, and prices were unchanged, with sales of finest creamery at 56c per lb. in solid packages, and at 57c in 1-lb. blocks.

We quote wholesale prices as follows:

Pasteurized creamery	..00c	to 56c
Finest creamery	.....54½c	to 55c
Fine creamery	.....54c	to 54½c
Finest dairy	.....48c	to 49c
Fine dairy	.....47c	to 47½c

The receipts of cheese today were 4,461 boxes, as against 2,326 for the same day last week, and 4,684 for the corresponding date a year ago. At Peterboro today the offerings on the board amounted to 1,067 boxes for which the bidding was slow, there being only two buyers present, and all sold at 30¼c per lb. which price shows a decline of ¾c per lb., as compared with two weeks ago. According to some in the trade there was no improvement in the demand for foreign buyers for supplies, and business this direction was dull, while others stated that some bids were coming forward for fair-sized lots, and as they were satisfactory in some instances, sales were being made, but the volume of business was not large.

THE PROVISION MARKET

Montreal, June 9.—A feature of the live hog situation was the weaker feeling which developed in the Toronto market on Tuesday, and prices scored a decline of $1 per 100 lbs., as compared with those paid last Thursday, wtih sales at $21.50 weighed off cars, and at $21.25 fed and watered. In sympathy with the above the market here today was also weaker, and prices for selected lots declined 50c per 100 lbs. and the prospects are that they will go still lower in the near ftuure. At the reduction there was a fair demand for what stock was offered, an sales were made at $21.50 to $22 per 100 lbs., weighed off cars, with the usual cuts of heavy weights, sows and stags. On account of the above there was also an easier feeling in the market for dressed hogs, and prices were 50c per 100 lbs. lower, with a small trade passing in city abattoir fresh-killed stock in a jobbing way at $30.50 to $31 per 100 lbs.

There was no change in the condition of the market for smoked or cured meats, prices being maintained under a good steady demand for domestic consumption, and a fairly active trade was done in a jobbing way in 8 to 10-lb. hams at 41c to 42c per lb., 12 to 15 lbs. at 39c to 40c, and heavier weights at 37c to 38c, while breakfast bacon sold at 44c to 45c, Windsor selected bacon at 47c to 48c, and Windsor boneless bacon at 49c to 50c. The demand for barreled pork is somewhat limited, and the market is quiet, with Canadian short-cut in a jobbnig way quoted at $58 to $60 per barrel.

A firm feeling prevails in the market for lard under a good demand for supplies for local and country account, and the movement is fairly large for the season, wtih sales of Canadian pure leaf grades in a jobbing way at 37c per lb. in 20-lb. wood pails, and at 38c to 38½c per lb. in 1-lb. blocks.

The receipts of provisions today were 3,794 pacakges tinned meats, and 182 boxes hams and bacon.

THE LOCAL FLOUR MARKET

Montreal, June 9—There were no important developments in the local flour situation today, prices generally being firmly maintained. The demand for spring wheat flour from local and country buyers continues good and an active business is passing for the season of the year wtih supplies ample to meet all requirements, and sales of car lots of Government standard grade for shipment to country points were made at $11 per barrel in jute bags ex-track, Montreal freights, and to city bakers at $11, ex-track, or at $11.10 delivered, while broken lots to city bakers sold at $11.10 ex-track, and to grocers and other dealers at $11.20, ex-track, all less 10c per barrel for spot cash. The demand for feed flour continues urgent and as supplies are none too large to meet the wants of the trade, prices rule very firm at $7 to $7.50 per barrel in jute bags. The trade in winter wheat flour is rather quiet on account of the fact that most of the large buyers have now ample stocks on hand for the present, and sales are now principally in small lots at $11.40 to $11.50 per barrel in new cotton bags, and at $11.20 to $11.30 in second hand jute bags, ex-store. The trade in white corn flour is steady and prices rule firm at $10.10, and rye flour is selling at $8.75 to $9 per barrel in jute bags, delivered to the trade.

MILLFEED AND ROLLED OATS

A very firm feeling prevails in the market for all lines of millfeed owing to the continued good demand for supplies for local and country account, and a large volume of business is being done with sales of car lots of bran at $42.50 to $43, and shorts at $44.50 to $45 per ton, including bags, ex-track, with smaller quantities of bran in mixed cars selling at $43.50 to $44, and shorts at $45.50 to $46, feed cornmeal at $70, pure barley meal at $62 to $64, mixed grain moullie at $62 to $64, mixed moullie at $56 to $58, dairy feed at $48, and oat middlings at $44 per ton, including bags, delivered to the trade. A good trade is reported in rolled oats for export account, but there is no improvement in the demand for domestic consumption and prices are unchanged with standard grades in broken lots quoted at $4.10 to $4.25 per bag of 90 lbs., and Golden cornmeal sold at $5.25 to $5.35 per bag, delivered to the trade.

Saved Thousands of Hay Crops

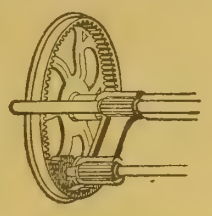
We can tell by letters from hundreds of enthusiastic farmers all over Canada who use the

FROST & WOOD MOWER

that thousands of hay crops have been saved because the Frost & Wood Mower, with the superior, life-long efficiency was on the job—tackling any kind of crop, "down" or standing and on the roughest kind of ground, and always ready for good work.

As soon as the wheels move the Knives start cutting

Light, but immensely strong, high carbon steel—and high grade roller bearings at every friction point give the famous F. and W. light draft. Convenient and easily operated levers give quick control—the knives go on cutting when bar is raised to clear an obstruction, saving time and crop.



FROST & WOOD "INTERNAL DRIVE" MEANS GREAT EFFICIENCY

See the little cut at the left—it shows a splendid F. and W. feature. Here is where the power is taken to operate the knives—a small wheel or pinion revolves on the inside of the power wheel, the cogs on each travel in the same direction, no tendency to fly apart, loosen or snap off,—means quicker-acting power and longer life.

Why not have "the best" on your farm too? See the Frost and Wood Mower when next in town. It's the Mower for you. You'll say so yourself. Write to-day for illustrated folder.

THE FROST & WOOD CO., Limited

Truro ST. JOHN, N. B. Charlottetown

CATTLE POISONED BY LEAD

In view of the spring clean up that is usual at the farm, I wish to say a few words to caution all livestock breeders against the use of lead paint in places accesible to stock while the paint is still fresh.

I just had an experience here on the farm. The painter, who was painting the hallway of my new stable retouched a small strip of the windows in the calf pens. Shortly following this the caves took sick. The diagnosis showed lead poisoning and we immediately removed all the calves from that stable, but even at that we lost four valuable youngsters.

This experience may save a loss to some fellow breeders. Whenever you see a paint brush used near stock, consider it a danger sign.—J. P. in Ottawa Valley Journal.

COSSAR STOCK FARM
Lower Gagetown, N. B.

Importers and breeders, Clydesdales, Dairy Shorthorns aed Border Leicester Sheep. Present offerings: 1 imported stallion, several young bulls, six to fifteen months old also a number of ewe and ram lambs for fall delivery.

FIRSHADE FARM
DUAL PURPOSE SHORTHORNS
Present Offering:—Two Bull Calves

No. 1.—Son of Daisy Lodge, R. O. P. 11,638 lbs. milk, 480 lbs. fat. This cow led the four-year-old class in the Canadian Record of Performance.

No. 2.—Son of Queen Charlotte. She as a two-year-old has a R. O. P. of 7224 lbs. milk, 316 lbs. fat. This cow stands eighth in milk and sixth in fat production in the two-year old class.

The sire of these calves is Nivalie, whose dam as a two-year-old has a R. O. P. of 5496 lbs. of milk, 240 lbs. fat in 295 days.

P. R. L. FAIRWEATHER, Rothesay, N.B

Maple Grove Farm Holsteins

Herd headed by the 32.32 lb. Sire "King Korndyke Johanna" No. 32915. 13 of his nearest female relatives average 34½ lbs. Butter in 7 days; his Dam and Grand Dam have each milked over 100 lbs. per day. Owing to the fact that we have decided to make some improvements about the farm this coming season, we have decided to reduce our herd to about half its present strength, consequently are offering some cows, heifers and calves that we otherwise positively would not put a price on. Cows and heifers due to freshen in March and April, others bred to freshen next November. Every thing with official Records or official Record Backing.

Phone or write for description and prices.

Jerseys and Shorthorns (Pure Bred)

Jersey Offerings for the Summer of 1919—

One 4-year-old Grade, heavy milker, due to freshen from pure bred bull, Oct. 11th, 1919.
Several pure bred calves, male and female.

Shorthorn Offerings for Summer of 1919—

One young bull (pure bred and registered), dropped March, 1918, of splendid parentage.
One 2-year-old heifer, due to freshen Dec. 1st, 1919, from imported English sire of milking strain.
Two yearling Heifer Calves, very thrifty.
One Bull Calf, dropped Jan. 16th, 1919.

ACCREDITED HERDS ADVISED

At last a plea for an "accredited herds" list has been heard at Ottawa. Speaking before the Common Committee on Agriculture, Dr. S. F. Tolmie, of British Columbit, president of the Canadian Holstein Breeders' Association, urged th eadoption of the accredited system as a means of dealing with the tuberculosis problem and of strengthening the position of Canadian breeders in extending their business both at home and abroad.

An accredited herd is one in which all of the animals in it are tested regularly for tuberculosis by government inspectors and all reactors eliminated. The accredited list is now an established factor in the breeding business of the United States. It owes its popularity to the abuses to which the tuberculin test has been subjected. It is now well known, for instance, that when an animal is purchased subject to the tuberculin test, the seller may render it immune by a previous injection of tuberculin. Safety requires a sixty-day retest and the quarantineing of the new purchase in the meantime is difficult and expensive. Where a herd is tested regularly by government inspectors however, there is little chance of dishonest practises and Dr. Tolmie is right in urging that the adoption of the acredited plan in Canada would be a factor in creating confidence on the part of buyers both at home and abroad. The problem of tuberculosis in pure bred herds has to be dealt with in some way at no distant date and this plan seems to be the best that has yet been suggested.

ALTERING PIGS

Boars may be castrated safely at 6 to 8 weeks old, but often it is not done until they are several months of age. An old boar, 18 months to two years, maybe operated on if he is designed for pork. After a few months' feeding the meat will then be free fro mthe strong flavor of boar or stag pork. An odd but easy way is to drive the old boar into a big barrel, quickly turn it up so the pig stands on his head, then with one man holding each hind leg the operation may be done easily and quickly. Bathe the wound with warm water containing sulpho-napthol or any good disinfectant. Where several animals are being cut, change the water so as to avoid possible contagion. Operate when the weather is warm. The older hte boar the better it is that he should have only light feeding for a day or two before or after castration.

HILLSIDE PETER PAN

Alex Hiene & Co., Campbellford, Ont., the well known Ayrshire breeders, have sold their champion bull, "Hillside Peter Pan," to George H. Stokes, of Tweed, Ont. Peter has been a champion winner at Toronto, Ottawa and London, and his progeny are promising.

"Hillside Peter Pan" was imported in dam and calved the property of C. P. Blanchard, Truro, N. S., who sold him to Alex Heine.

Glenrane Farm Holsteins!

We have a nice bunch of well grown Bull Calves for sale. These are well bred calves, fit to head any herd.

For particulars apply to

ROBERT C. HICKS
WEST BATHURST - - - N. B.

FOR SALE !

We have an exceptionally fine litter of 13 (living) of our large Berks for sale @ $12.00, four to 6 weeks old. Ready first of June.

Owing to scarcity of labor and we not being able to see eye to eye with certain Gov. officials, as to the type of Shorthorn to raise, we have decided to go out of the breeding and raising of pure bred live stock. Therefore our herd of 40 head of Shorthorns will be sold between now and fall for either breeding or for beef. Parties wishing to buy, please come and see them. We have seven very nice bulls, 10 months to two years.

L. M. ANDERSON, Sackville, N. B.

Milking Shorthorns for Sale

We are offering some choice young Shorthorn bulls of the milking strain, ages 3 months to 15 months.

Also a limited supply of heifers, one and two years of age.

For particulars apply to

KEEP Holstein-Friesian Cows

1. The Holstein-Friesian is a large vigorous cow, full of energy and abounding in vitality.
2. Her physical organization and digestive capacity are such that she is able to turn to the best advantage the roughage of the farm, converting the same into merchantable products.
3. She yields large quantities of most excellent milk, fit for all uses and especially suited for shipping purposes.
4. Heredity is so firmly established through her long lineage that she is able to perpetuate herself for the production of strong, healthy calves.
5. When for any reason her usefulness in the dairy is at an end, she fattens readily and makes excellent beef.

If you can't buy a herd, buy a heifer

In and About Your House

AND BARNS WITH

Northern Electric

POWER and LIGHT

NORTHERN Electric Power and Light means *Power* to do most of the chores in half the time, doing away with a lot of hard work.

It means *Light*—a good supply of happy, clear, safe, glowing electric light—better than you ever had the old way.

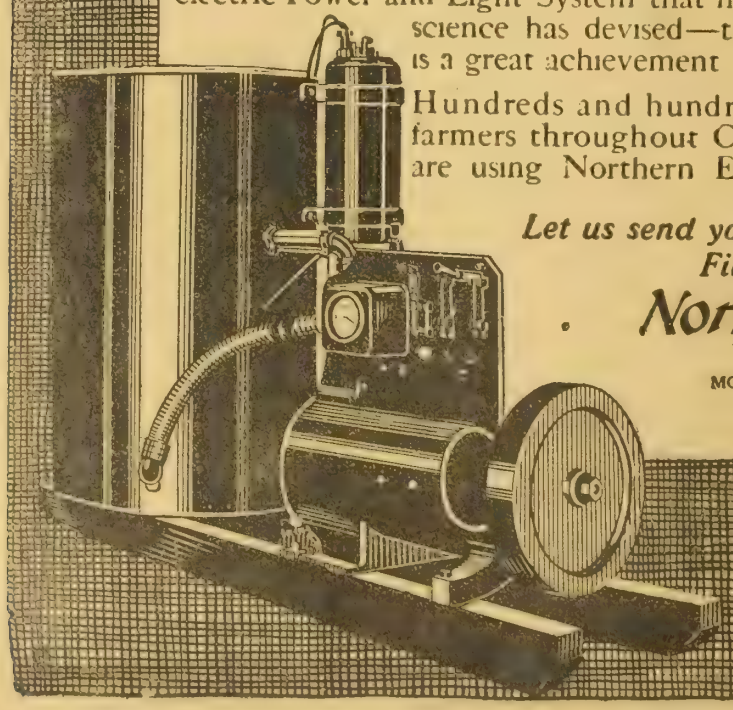
Never in the history of isolated electric generating systems was there an ideal so reliable, so successful as *Northern Electric Power and Light* It has all the finishing touches to make it the most complete, efficient, reliable, economical electric Power and Light System that modern science has devised—truly it is a great achievement

Hundreds and hundreds of farmers throughout Canada are using Northern Electric Power and Light with intense satisfaction, and you, too, can very easily become one of them.

Electricity will turn the grindstone, cream separator, grain grinder, churn and a host of other chores about the farm. It will clean the house, wash and iron clothes, wash the dishes, cool the home, and do a score of other household tasks all at a surprisingly low cost.

Northern Electric Power and Light is automatically controlled—simple and easy to look after. Back of it is more than twenty-five years of electrical experience, a Dominion-wide distributing organization with complete stocks in nine of Canada's largest cities.

When you buy Northern Electric Power and Light you get a system which enjoys an international reputation—a means of easily procuring almost every kind of electrical appliance built especially for this service, such as Northern Electric lamps, wire, motors, pumps, irons, sewing-machine, vacuum cleaner, etc. See that your whole electric outfit is Northern Electric.



Let us send you some interesting illustrated leaflets to-day.

Island Fruit Growers' Associations, The Maritime Stock Breeders' Association, The Maritime Bee-Keepers' Association and The Newfoundland Agricultural Board.

Volume 24. SUSSEX, NEW BRUNSWICK, JUNE 24, 1919. Number 18.

THE IDEAL DAIRY BARN

How to Build and Equip it

The two plans of barn roofs most commonly used are the gable and the gambrel, sometimes incorrectly called the "hip" roof.

The gambrel roof, has the advantage of giving more hay room under it, without building any higher at the plate or the ridge.

The rule generally followed in building the gambrel roof is to fix the height at half the width of the building. The first rafter will have a rise of one-third the width of the building and a run of one-sixth. The second rafter will have a run of one-third the width of the building, and a rise of one-sixth. In a 36-foot barn, the lower rafter would have a rise of 12 feet and a run of 6 feet. The second rafter would have a run of 12 feet and a rise of 6 feet.

It is only within recent years that the arrangements and construction of the dairy barn has been given the attention that its importance justifies. Farmers now relaize that it pays to have a comfortable barn on account of the large production of milk which follows. The growing demand for better sanitary conditions surrounding the milk supply, means that greater attention must be paid to the details of barn construction, if we are to get sanitary conditions without too much labor.

The style of barn to build will of course vary with the location, size climate and many other factors. However, it should be remembered that a barn once built is likely to remain there for a long time. It is therefore very important that it be built right, that is, convenient in arrangement, of proper proportions, easy to ventilate and suitable to the place. A barn can give character to a place; it may either have a pleasing effect, add value to the place and be a source of pride to the owner, or it may be an unsatisfactory eyesore to the farm and its surroundings. But it is just as easy to build one as the other if a little time spent on thought and planning at the right time. It does not cost any more to build a satisfactory one, and the comfort and pleasure besides the time saved in the life of the barn, are worthy of the most thoughtful planning. Whatever plan of barn is adopted, however, it should be placed with a view to convenience of access, and in keeping with other buildings or additions which may be erected in the course of time. Further, care should be taken to have the buliding located so as to permit of easy and thorough drainage.

Style of Barn

The first problem to be solved is what style of barn to build. Will the feed storage and cattle be under the same roof, in separate buildings or in separate building joined together. In other words; shall we build a basement barn, a storage barn and cattle shed or combine the two forming an L or T shaped barn. Generally speaking either the basement barn or the L or T shaped barn are the most popular in Central Canada. Both styles have their good and bad points but a great deal will depend upon the location and surroundings. If the barn is to be built on the side of a hill, the basement barn will give excellent satisfaction; if on the level perhaps the L or T shaped barn will be found better.

The advantages claimed for the bank barn are, economy of building, easy accessibility to feed, and reduction in cost of labor.

These are strong arguments but against them we can generally obtain more light and easier ventilation, less dust, and have the barn floor on the ground when using an L or T shaped barn. The latter is worthy of consideration, especially in threshing, as some difficulty is encountered in operating heavy threshers and engines on the elevated floor of the bank barn. After years of experience with bank barns the writer feels free to admit his preference for the L or T shaped barn, and would hesitate to build a bank barn unless a very favorable location was presented.

The interior arrangements of the stable may be much the same, regardless of the style of barn built. The cows should be arranged in two rows running lengthwise of the stable; whether they face the wall or a central feed passage is a matter of individual preference. At any rate, the stable should not be any wider than will accommodate two rows of cows, and allow ample room for feed passages and a good wide walk behind the cows. If any greater width is attempted great difficulty will be found in obtaining sufficient light and it will be harder to keep the stable cattle clean. By having the cows face a central feed alley they may be fed with less labor than if facing the outer walls but that is about the only advantage that can be claimed for that arrangement. By having the cows face the wall greater convenience is experienced in cleaning, milking, tying up the cows and keeping them clean. Feed is light and it is easier work to carry it along two rows than to carry the manure even if a little carrier is used. Handling manure is heavy work at best and should be made as convenient as a situation will permit. If a man contemplates installing a mechanical milker (and all dairymen will in time), he should, if at all possible, have his cows tail to tail, as he will find it much more convenient to operate the machine than if his cows stand facing inwards.

Good Lght Essential

The cow stable should not be more than 36 or 38 feet wide or difficulty will be found in obtaining sufficient light. The windows should be placed close together (the closer the better) on all sides of the building and should be of good size and extend up to the ceiling. There is nothing that will kill germs and keep cattle healthy and free from vermin like plenty of sunlight, and it is the cheapest disinfectant we can obtain.

Have Cement Floors

Cement makes the cheapest, cleanest and most lasting floor of any, does not wear out and if properly made, will not injure the cows in any way.

The feed passages should be 6 or 8 inches higher than the manger bottom. It is much easier and much quicker to feed down into a manger than to lift the feed overa wall no matter how low it may be. The average dairy man has no time to bother with such things. The gutter should be deep if the cows are to be kpet clean without too much labor. Here is one of the secrets of keeping cows clean—have the gutters deep enough that the cows will not step back and stand on them; 9 or 10 inches is not too deep if the walk behind can be lowered enough. The walk behind the cows should be 3 or 4 inches lower than the platform the cows stand on. This gives the cows a much better appearance as well as making it easier to clean out the gutters. The platform under the cows should be a few inches shorter at one end of the row so as to accommodate small cows.

Methods of Tying

There are two methods of tying that are generaly adopted today, the swinging stanchion and the chain tie. Either of these will give good satisfaction if properly installed. The chain tie gives the cow more freedom, greater ease in rising and if properly installed keeps her just as clean as the stanchion. The double chain system is much superior to the single chain in that it allows the removal of stall partitions and yet keeps the cow from interfering with her mate. The chain should be fastened to a pipe at each side of the stall, and the cow tied to the centre of this chain, either by another chain or a leather strap. This system is used almost exclusively on the Island of Jersey and is rapidly finding favor in America. It is cheap, light, and best of all, makes very litte lnoise.

Watering System

Dairy cows should be watered in the stable and have an abundant supply of water at al ltimes. The individual water-bowl system gives good satisfaction in warm stables and once installed is perhaps the handiest of all. The continuous trough and the watering manger both give good results and are used in some of the best stables.

Box Stalls

No dairy barn is complete without a few box stalls. The number will depend upon the kind of dairying followed. Whether purebred or grade cattle the handled. At any rate it should have a bull pen, one or two box stalls and a few calf pens. These should be constructed of piping is possible. Patent steel stable fittings are not expensive and give good results.

Ventilation

A stable may be fitted up with every convenience that money can buy but unless it has ventilation it is useless. It has been claimed by one of Canada's leading agriculturists that proper light and ventilation in the stable would produce more milk than five pounds of meal daily. If that is so a proper system of ventilations should soon pay for itself. What is the proper ventilation? That is just the trouble; we have no ideal system, neither have we a system, neither have we a system that works automatically and gives good results. They are all subject to varying conditions of wind, temperature and humidity and must be regulated by hand at al ltimes. Perhaps for Central Canada the Rutherford System gives better results than any other. That system admits cold air a tthe floor while the fould air is removed through ventilators starting at the ceiling and leading out through the roof.

The King system works well in a warmer climate. It removes the foul airs from the floor and receives the old air at the ceiling. Both these systems have their advantages but neither of them are perfect.

Finish of Walls and Ceiling

The walls and ceiling should have sufficient boarding and paper to keep out the cold but they should also have a tier of dressed lumber or v-joint on the inside of the studding and under the joints. This enables the men to keep the stable clean and also allows for white washing without any great amount of work.

Carriers and Trucks

Loading manure directly into a sleigh cart or spreader is the easiest and quickest way of cleaning stables but is not practical at all times of the year. The litter carrier is a great improvement over the old wheel barrow but even the best of them cause more or less trouble at times. Its greatest help is in the spring when it is too soft to use a horse and cart or even a wheel barrow. By using a swing pole a neat, compact silo can be made of the manure with very little extra effort.

For carying feed the large three-wheeled truck is in the writer's opinion the most satisfactory, easiest to

(Continued on page 960)

Central Stock Yards for the Maritime Provinces

Mr. Dan Johnson of the Stock Yards Division, Live Stock Branch, Ottawa, recently toured the Maritime Provinces to get first hand information re the Live Stock situation here, and look over probable sites for the erection of Central Stock yards.

For many years the farmers and stock breeders of New Brunswick, Prince Edward Island and Nova Scotia have been badly handicapped in the sale of their cattle, sheep and swine through the lack of stock yards facilities. Very few farmers ship their surplus stock direct to the stock yards at Montreal and Toronto. The shipping is customarily done by drovers and traders, and conseuentlqy our farmers have not heretofore realized the full value for their stock that they would had they shipped the stock themselves. On the other hand the long freight haul and consequent delays cause a large shrinkage in live stock, which will be eliminated when the central yards become operative.

The Maritime Stock Breeders' Association has been advocating the establishment of such yards for many years and now in response to their request and the unanimous support of the three local governments, the federal government is preparing to comply with their wishes.

Following the organization of the stock yards will probably be the erection of abattoirs and cold storage facilities.

With better marketing facilities in sight our Maritime farmers will be well advised to increase their live stock breeding herds and flocks to their maximum capacity.

On Mr. Johnson's return to Ottawa he reported the urgent necessity for the establishment of the stock yards in the very near future, and summing up all conditions for a site, recommended that they be located in Moncton, where there is a large consuming public and splendid railway facilities for rapid transit from and to all parts of the Maritime Provinces.

The federal Live Stock Branch requested the Maritime Stock Breeders Association, who have been the agitators for stock yards facilities, to choose the centre at which they would like the yards located. In compliance with this request, Mr. F. L. Fuller, the secretary of the Association, issued invitations to the prominent stock breeders of the three provinces to meet in Amherst, N. S., on June 16th. Besides a representative attendance of the stock men, representatives of the City Councils and Boards of Trade of Moncton, Sackville and Amherst were present to press the claims of their respective towns.

A. E. Trites, president of the Maritime Stock Breeders Association, presided. Among those who addressed the meeting were Dr. M. Cumming, Secretary for Agriculture, Nova Scotia; Hon. Murdo McKinnon, Minister for Agriculture, Prince Edward Island; E. P. Bradt, Deputy Minister for Agriculture, New Brunswick; C. H. Reid, President Amherst Board of Trade, Hon. C. W. Robinson, Acting Attorney General for New Brunswick; His Worship Mayor Rogers, Amherst; His Worship Mayor Black, Sackville; His Worship Mayor Price, Moncton; His Worship Mayor Beulley, Kensington; Mr. Fraser of the packing firm of Davis & Fraser; Mr. Crosby, President of the Prince Edward Island Stock Breeders' Association; Mr. Matthew Lodge, Moncton; Fred Magee, M.L.A., Port Elgin; Mr. Samuel Freeman, Amherst; F. L. Fuller, Secretary of the Maritime Stock Breeders' Association; C. C. Avard, Editor Sackville Tribune; Mr. Weldon, Canadian National Railway; R. E. Mutch, President Charlottetown Board of Trade; Hon. Josiah Wood, Ex-Governor of New Brunswick; Mr. A. N. Griffin, New Minas, N. S.; Mr. J. A. Marven, Moncton; Mr. H. J. Logan, Amherst; Mr. W. B. Fawcett and Mr. Chas. Fawcett, Sackville and Hon. Frank Sweeney, Moncton.

The need for the stock yards was apparent to all.

The Prince Edward Island delegates favored Sackville, whose claims was so ably presented by His Worship Mayor Black.

Some favored Amherst owing to the central location and good treatment accorded the Stock Breeders while there in connection with the Maritime Winter Fair.

Moncton's claims for central location, railway facilities and large consuming nd growing centre were advocated.

On motion the final choice was left in the hands of the Directors of the Maritime Stock Breeders' Association, who at a subsequent meeting voted in favor of Amherst, there being only two dissenting voices, viz., W. S. Harding and W. W. Hubbard.

The Federal Live Stock Division may not see eye to this decision, but it will make very little difference which one of the three towns is finally chosen, the main question at issue is to get the stock yards established and ready to do business as soon as possible.

Mr. Fraser of the firm of Davis & Fraser asked some pertinent questions, the majority of which clearly indicated that the great Diana of the Ephesians was about to be jeopardized. Had he remained in the audience long enough to get the answers to his questions, he would have hard some pertinent questions from the farmers' standpoint, ably propounded by Mr. W. B. Fawcett of Sackville and some of the P. E. Island Stock Breeders, who wished to know why live hogs were at times bringing as much per pound on the Toronto and Montreal stock yards as Mr. Fraser was paying per pound for dressed hogs, but Mr. Fraser did not wait. Had he waited he would have soon recognized that the farmers who comprise the Maritime Stock Breeders' Association are just as keen and bright as are the devotees of the packing business and are going to govern themselves accordingly. Farmers will not stand bluffing any longer.

Will Unionism Spread to Farm ?

If the spirit of labor unrest, which has all but paralyzed .industry .and commerce in the Dominion for the time being should spread to farm laborers how would the situation bt met by farmers, or on what basis could a settlement most likely be effected? The mere mention of this subject may probably be greeted with a smile by a good many farmers, who have been in the market for hired help for a year or two without results, and are now almost ready to believe that the hired man has completely disappeared, but no one at all familiar with both farm and city conditions, would attempt to deny that the present distribution of labor is all out of joint with the needs of the moment. The muster roll of unemployed in the big centres of population seems to be steadily on the increase, while the farms throughout the country are badly handicapped on account of labor shortage and all sorts of schemes are being adopted to keep things moving. But the story of the past has shown that situations such as exist at present gradually right themselves; the tide flows from country to city until a certain point is reached when reaction sets in, and the procession turns back in the opposite direction. When this movement begins—and there is every evidence that it cannot be much longer delayed— and the tide which has taken the farm workers to the factory brings them back once more to their places on the farms, with advanced ideas on trades unionism, 44-hour weeks, etc., then the farm labor question will take on a different appearance, and the farmer may have to deal with his help on the principle of collective bargaining. This may sound like a far fetched idea but nevertheless a farm laborers' union has been in operation for sometime in Great Britain, and what has happened in one country is at least a possibility in another.

Why Labour Asks 8-Hour Day

One of the outstanding demands in practically all of the recent strikes has been for a 44-hour week. This means nothing more or less than an eight-hour day with half a day off on Saturday. Could such a time schedule be applied to farm operations? If such a thing as a farm workers' union came into being in Canada would an attempt be made for any such concession on the part of the union members? Perhaps if we could get at the reason why the industrial labor unions involved in the present strike demand an eight-hour day, it might throw some light on the question. The labor men—or at least some of them—assert that the shortening of the day to eight hours is an attempt to relieve unemployment and to make the available supply of work go around. If this really is the bed-rock reason for all the hue and cry that has been raised for the shorter day, then even though farm workers should decide on a union, many a wet day, and many a dry one, will pass before there will be any necessity of resorting to such a measure as this to provide work for all available hands. Just at present farming comes much nearer being a 24-hour-a-day game than a 44-hour-a week proposition, and there is room for a great many more hands without any danger of congestion. .

A 44-Hour Farm Week?

The question naturally arises if a 44-hour week would be a possibility under any ordinary set of condition. Decidedly no. To attempt to carry out such a schedule where mixed farming is practised, or where dairying is carried on would be sheer nonsense. Even on farms whose owners have not the reputation of being early risers, and wheer the amount of help is normal, work starts at 6 a. m., and is seldom if ever over before 6.30 p.m. Deducting half an hour for the morning meal, an hour for dinner and an hour for the evening meal leaves an actual working day of ten hours and a half. This repeated six days per week gives a total of 63 hours—practically one-third longer than the week organized labor is endeavoring to bring about.

Then too the fact that farm operations are very largely dependent upon weather conditions, is another factor which makes it still more difficult to adhere strictly to any set number of hours as a day's work. At certain season's of the year, which scarcely need be enumerated here, a great deal of work has to be put through in a short time, while there are other periods which are correspondingly slack. But the suggestion may come, "Why not pay an excess wage for overtime work during the seasons when there is a distinct advantage in working long hours to hurry things along?" Probably this could be arranged, but some different scheme from the present one for gauging the remuneration of farm workers would have to be adopted.

How British Farmers Do It

In Britain not only the farm servants, but the farmers as well have their unions, and but little friction between the two sets of organizations is reported. The standard day consists of nine hours in the field, plus whatever additional time is needed by the worker to tend his team, or to do whatever share of the stable work may be allotted to him. Workers are entitled to ten legal holidays during the year, and Saturday afternoons off in their turn. Provision is made for the payment of overtime wages during the haying and harvesting season. Special stress is laid on the provision of proper housing accommodations for married farm workers; indeed, so important is this feature that the Government has taken the matter up, and if legislation has not already been enacted compelling the landlords to provide suitable housing accommodation for their men, it is on the way.

A discussion of the possibility of trades unionism extending to include farm labor, and the probable course of events if such happens, may seem premature, but developments in the labor world have been coming forward so quickly of late that a person scarcely knows what to class as possible and what as impossible. Two weeks ago the average man would have classed a general strike big enough to tie up a whole city as absolutely out of the question in Canada. But now we are witnessing the spectacle of simultaneous general strikes in the cities of Western Canada, with the immediate possibility of the movement affecting all the principal cities of the Dominion. To be forewarned is to be forearmed, and although the matter of trades unionism has not as yet actually reached the farmer's doorstep, it would seem to be the part of wisdom, judging from the present trend of events, for him to at least give the matter some thought, so as not to be caught napping should the unexpected happen.—Ottawa Farm Journal.

A good test for determining when clover or alfalfa hay is ready for the mow is to twist a few of the stalks, and if no moisture can be squeezed out, it has cured sufficiently to keep in storage without moulding, and is in the right condton to prevent loss of leaves during handling.

Nothing looks better than smooth, clean carpet of green grass covering the yard and surrounding the home.

Under-drainage Insures Crops

The Experiences of two Large Farmers

"Farming is becoming more difficult every year," said an exasperated and overworked farmer to a representative of a Farm Journal the other day. Asked what the trouble was, he could not say, although he pointed out that help was scarce and wages high. Last fall was so wet that little plowing had been done upon his farm, and this spring the continued rains had delayed seeding several weeks, with the result that the fields weer rapidly becoming overrun with grass and weeds. Moreover the roads were almost impassable in his district and it was a daily occurrence to be called upon to help some unfortunate traveller out of a mud hole. The country church in this particular district had been closed because the people could not go through the mud! He had to stop shipping his milk to the city for the same reason, and his wife was at her wits' end to find dishes in which to store the large quantities of butter that had to be made at home. This man operates a dairy farm, and his Holstein cows produce several cans of milk daily. What could he do? Truly it was an extreme and pitiful case, but no assistance could be given. Yet this man believed in the farm. He would not forsake the land, and said he was anxious to buy another farm for his son, who was rapidly approaching manhood. He has two sons who are going to be farmers. They are deeply interested in the breeding of pure-bred cattle and horses, and will be heard from later, for such indomitable perseverance cannot go unheeded.

In discussing this very same matter with another farmer in an adjoining county it was surprising to find how cheerful he appeared to be. He had to travel muddy roads and frankly admitted that he could not remember seeing them as bad, but fortunately he had a gravel road from his place to the station, which was passable, although far from good. But that was not all. He had most of his plowing done last fall, and only a few acres of corn stubble remained to be turned over this spring. He had about half his grain crop sown and it was growing fine. His farm was situated not many miles from the first mentioned reader and if anything it was lower and contained less rolling land.

Why the difference? The answer is simple. A number of years ago the latter became convinced to the benefit of under-drainage and has been laying tile every year until the war broke out, when he had to quit on account of the labor situation. The wet weather of last fall and this spring have not dampened his optimism on drainage, but on the other hand has greatly accentuated it, and he is planning to continue the work. Last fall, when it was impossible to plow the undrained land, a tractor was turning over several acres a day over the tiled area. It was the same this spring' The drained land was dry several days before the undrained and sown before the rains started. True, he felt the backwardness of the season a great deal, but not as much as the first mentioned farmer. Why should he? He was better fortified against unfavorable weather conditions. This man had sons growing up also and they were not longing for the time to get away from the farm. No. The good stock and progressive farming methods employed on this farm meant too much to them. They will "carry on" and there is little fear but they will make good use of their rich inheritance; a good farm and an appreciation of good farming methods.

Of course the two cases cited may represent rather extreme instances, but they serve to illustrate splendidly the value, preparedness and fortification against an emergency. The day of "slip-shod" farming methods is over; the day of carelessness is gone, and in its place must come an age of preparation and watchfulness to guard against the unexpected which is the rule rather than the exception in this tumultuous era. Strikes are the order of the day, some are justified, many are not, but if the farmers would strike a blow for better drainage, and carry it out, there would be fewer discontented farmers throughout the country. The unfavorable weather of last fall and again this spring should leave no doubt in the minds of all fair-minded men as to the value of such work. The drained land was fall plowed and was sown early in May and in some cases in April. The crops are most promising at present, while the undrained land is flooded with water. What will happen? If it dries up quickly a fair crop may be expected, but with all the land left unplowed last fall the prospects for a bumper harvest are not very bright.

In view of this there should be no hesitation on the part of farmers as to the value of under drainage. If the wet weather continues much longer the harvest will be greatly reduced except upon well drained farms, and such a loss even for one year would go a long way towards paying for a system of tile drains. Furthermore it would give the farmer a greater guarantee or assurance of a crop. That might not have been so bad in years gone by, when a large part of the crop grown was sold off the farm, and the only loss suffered a shortage in cash revenue, but not so today. Most farmers in Canada aim to carry all the live stock they can feed, and they depend upon a crop every year. If it fails they are in a serious situation. They have the stock on hand, no feed, and what is still worse no money to buy it. The situation is too serious to take the risk, but the remedy is not hard to find. Although it would be foolish to advicate drainage as a cure for all ills yet it will go a long way towards insuring a crop year after year which in the end is what is needed. Prosperity in farming does not come by spurts but by steady, faithful work year after year, and paying careful attention to small details. There is no better time to decide upon better drainage than right now, and it does not require a complete survey and taking of levels to tell the farmer what fields require it.—O. V. J.

The Ravages of Tuberculosis

Tuberculosis is the oldest disease known to science, and is also the most common. It is particularly the disease of the white man, and prevails most virulent in all temperate climes. No less than one-seventh of all mankind perish from one or other form of it, while it accounts for one-third of all deaths during the working age. Most of the animals that are associated with man on the farm are liable to take it. It affects cattle of all breeds, but the percentage of mortality in various breeds cannot be arrived at. Pigs, dogs, cats, poultry, and wild animals in captivity are susceptible. It is plainly evdent that captivity and domestication is the chief medium of its rampant origin. The Ottawa Farm Journal believes had it been as common among animals in their wild state many of the species would have been extinct long ago. The modern efforts of treating domestic animals for the single purpose of production has lost sight of the natural methods of health, and tuberculosis has consequently taken a firm hold.

Predisposing Causes

Although the actual cause is the microbe, there are many predisposing causes, conditions which render the healthy body open to an attack. **The most fertile predisposing cause is domestication. Animals at large, living in the open, year in, year out, are least liable to be affected. Animals which are badly housed, retained in confined space, without sufficient ventilation and air space, and under bad sanitary conditions, are most commonly affected.** To this must be added all causes which weaken the constitution, such as early and frequent breeding, heavy milking, forced feeding, and keeping the stables at a high temperature. The opposite conditions have a similar effect. These are insufficient and innutritious foods, previous existing disease which has lowered the constituton, pneumona, pleurisy, etc. In-and-inbreeding and line breeding also play a part if such breeding is done with animals having the hereditary taint of tuberculosis. Another very important factor is hereditary predisposition which accounts for the disease running in certain families and certain breeds of cattle. The hereditary predisposition, however, operates in the case of most diseases. One might state that children or animals born of diseased parents are, as a rule, more liable to that particular disease than are those born of healthy parents.

How the Disease Enters the System

How does the microbe gain entrance to the system? Infection is mostly due to direct contact or co-habitation. It may occur through a contaminated atmosphere, in which case the germs are haled directly into the lungs, but it is mostly by means of secretions, such as saliva and mucous from the mouth, or by tuberculosis material coughed up from the lung of an infected animal. Such material infects stables, stalls, and food. The calf is often infected by the milk from a tubercular udder, and human beings in the same way. When the organism is eaten it gets absorbed from the intestines, enters the lymphatic system, and is carried and deposited in various parts of the system. In young animals it generally affects the glands along the intestines in the first instance.

Every organ in the body can be affected with the exception of the muscles, and a varied set of symptoms is set up according to whatever structures are attacked.

Symptoms of the Disease

In young cattle the glands of the throat are often attacked, producing the condition known as a "snorer," that is the breathing is accompanied by a snoring sound. It may only be slight, but if it is heard at all, it is to be suspected that the microbe has entered the system. The spinal cord is also a common seat, while many subscribers taking the Maritime Farmer, as indicated in letters addressed to the information department of this paper, find symptoms like paralysis of the fore or more commonly, the hind limbs, due to tuberculosis of the brain. In tuberculosis of the udder, which occurs in about two per cent, of all tuberculous cows there is generally a very slowly developing swelling of one or both hind quarters of the udder. Unlike an ordinary weed, there is no pain nor tenderness in the swelling, and the overlying skin can be pinched up from the gland below. The swelling has generally well defined though irregular edges, and at times one may find numerous individual nodules. The milk for a considerable time remains unaltered in quantity or appearance. This mitigates against early diagnosis, and the milk may be infective to human beings and calves for a time before the diseased gland is diagnosed.

Preventative Measures.

As far as preventative measures are concerned, the broad principles of hygiene and disinfection must be observed. Tuberculosis animals should be kept separate from healthy ones, and all animals which cough, and are in any way suspicious, should be isolated, and if not of particular importance from the breeding point of view, fed for the butcher as early as possible. All unthrifty and emaciated animals should be destroyed.

The most approved system of eradication is that introduced by Prof. Bang, known as the Bang system. This scheme is based on the fact that contagion plays a principal part in the spread of bovine tuberculosis, that the calves of tuberculous cows are generally born healthy, but are generally contaminated with material coughed up from the lung of the infected dam.

A Royal Commission was appointed in Britain to inquire into the relationship between human and bovine tuberculosis, and after a period of work, comprising the ten years previous to the war, they distinctly proved that the two diseases were one and the same, and that human beings are often infected by drinking tuberculous milk. They also showed that 50 per cent. of the children that died from abdominal tuberculosis were directly infected from cows' milk.

The danger is so great from infection that every energy by Government and people should be directed towards its eradication, and for this end every available channel of information regarding its history and methods of infection and preventon, should be made sufficiently clear to every citizen of the realm.

MILLFEED AND ROLLED OATS

Montreal, June 23—A good steady trade continues to be done in most lines of millfeed and the market on the whole is fairly active, with a firm undertone. Sales of car lots of bran were made at $42, and shorts at $44 per ton, including bags, ex-track, and smaller quantities of bran in mixed cars sold at $43 to $43.50, shorts at $44.50 to $46, feed cornmeal at $70 pure barley meal and mixed grain moullie at $62 to $64, mixed moullie at $56 to $58, dairy feed at $48, and oat middlings at $44 per ton, including bags, delivered to the trade. The trade in rolled oats is quiet and prices are unchanged, with broken lots of standard grades quoted at $4.10 to $4.25 per bag of 90 lbs., and Golden cornmeal at $5.25 to $5.35 per bag, delivered to the trade.

AN AID IN LIVE STOCK BREEDING

For a century now the parallel line to the Agricultural Fair has been agricultural progress. The fair is now recognized as the most important agency in stock improvement. As an advertising medium it has its advantages to individual breeders by affording the opportunity of making acquaintances and selling stock. But these are minor matters to formulation of ideals and the elevating of standards that fairs have given inspiration to, ever since their inception. The history of the national and local fairs in all countries has proved their value in stock improvement, by answering the question that mentally arises in every aspirant to the cult of live stock breeding on the farm, "How is a good animal or sire to be known?" Without the show ring as a guide in the selection of sires, breeders would grope in the dark and progress would be slow.

The times require more constructive breeders and fewer speculators and other parasites of the pure bred live stock industry. Higher costs of feeds and increased necessity for their economical use require that inferior live stock be scrapped as rapidly as efficient stock can be produced to supplant them.

Booming any family or bloodline into notoriety by other methods than those of sheer merit, has done a lot of damage to the industry. Many attempts have succeeded in ultimately lowering the standard and the values and therefore the popularity of the breed. Booms that explode always willl react against the favor or popularity of the family or breed experimented on. They are generally built up on bloodlines that have been unskilfully handled, and generally die the natural death that comes to all operations in breeding similarly conducted.

But the fairs take entirely a different tack and sail for a different port. They have all along made utility and its highest ideals their starting and finishing points. The responsibility of the fair and its judges is great. If errors occur in the type set or in awards made much damage may be done. But they are unusually free from error or partiality and therefore do untold good.

In no other class of showing have showyard verdicts dominated breeding more than with the Clydesdale. Excellent and hige devedopment of type, character and uniformity in the modern Clydesdale are very largely due to the careful judging practiced in Scottish shows, and the acceptance of the showing verdicts as law.

Winning exhibitors and winning animals are always greatly benefited, but he who takes a lesson from defeat, corrects his type, changes his sire or improves his methods of feeding and fitting, is thrice blessed, and will return in time a winner. Fairs benefit those and the young breeders most of all.

HAVE CLEAN-UP ABOUT THE BARN

Any farmer might take a few pointers from his wife about cleaning up around the barn. The average farm barn is not a model of neatness. Refuse of all kinds is stored away in the corners, old hay and chaff litter up the floors and without a doubt there is an accumulation of manure in the horse and cow stalls, or else it is piled up just outside the door.

The housewife is in torment every spring and fall until she has her house gone over and given a general cleaning from the attic to cellar. She looks upon this work as a sacred duty that must be performed before she can face her neighbors, but the farmers are few who follow any kind of a cleaning programme about the barn. The manure may be hauled out in order to keep the horses from having to stand on their heads to get into the feed mangers, but anything like a general clean-up is unusual.

If farmers would make it a regular job to clean the premises once or twice a year, infectious diseases among farm animals could be more easily controlled and the mortality from calf scours, hog cholera, blackleg, contagious abortion and other disease might be reduced to a minimum. And it would make the work round the barn during the rest of the year much more pleasant.

BY ITS HORSES A COMMUNITY IS KNOWN

Where is the vast difference between $15 and $25 stud fee? Mostly in the imagination, for the stud fee is a minor part of the trouble and expense. There is the loss of part of the usefulness of the mare, and the cost of raising the colt, and $10 will bear a relation to the whole of less than 5 per cent. Often there will be good and poor horses etanding at $15, and for $2 or $3 more mares can be sent to good horses. This would prove a remunerative day's work whether the owner did it or hired it.

Breeding to poor, unsound stallions is to give direct encouragement to their owners, and to prevent good horses from coming to the neighborhood. There are all grades of stallioners, and if mare owners are indifferent how can they expect to have good stallions? The class of stallions standing in a district is a direct reflection of the horse knowledge of the community. If the stallions are bad it is a foregone conclusion that the farmers know little of horses, and will have poor stock.

A TOAST TO THE FARMER

Here's health to the farmer, the man of the hour, the man who feeds all the world by his power! His work in the Garden of Eden began; 'tis the God given occupation of man. Independence is one of his blessings most rare; no master has he—he's free as the air. In the early morn to his work he's away, thus gaining the freshness and beauty of day. His ears are attuned to the song of the birds, which lighten his toil as his loins he girds for the work in the field, while the health-giving breeze sings its sweet catin song in the tops of the trees.

The spring with its fragrance of blossoming flowers, the summer with ripening grain and cool showers, the autumn with fruits and foilage bright, and lastly the winter with all its delight—each season to him great joy does impart, for he lives the nearest to Nature's heart; and he looks up from Nature to Nature's great God, learning lessons of faith while turning the sod, and happy is he for he knoweth full sure, that "seed time and harvest shall ever endure."

He tills his broad fields with intelligent skill; with his heart in the labor he works with a will. He spends not his evenings in ways that are strange, but takes wife and children and goes to the grange. Thus in ways "safe and safe sane" his time is well spent. Though he may not have wealth he is quite well content, for he never need look to the future with dread, as he who feeds others is sure of his bread. Of true happiness he never has dearth, so a health to the farmer, the salt of the earth!—Alice E. Wilbur.

UNDER-DRAINAGE PAYS

There is no one thing today that will increase the productiveness, and assist in the development of agriculture in Canada, more than under-drainage. The less humus in the soil the more need of under-draining, because the soil becomes more compact, and retains the water that is not needed for growing plants. The air cannot get into the soil unless the water is out and it is absolutely necessary that plant roots have air.

The season for work is much lengthened by under-draining, for under-drained soil can be worked much earlier in the Spring and much sooner after a heavy rain. The field will be found more even and there will be no wet places, while other aprts are dry. An under-drained farm becomes more fertile every year, as more of the fertility contained in the subsoil is made available.

There is no better investment for money than in under-darinage; it will pay a larger rate of interest than any other investment made on the farm.

In a future issue we will give the experience of some Maritime Farmers with under-draining.

* * *

You cannot hope to make sales of live stock —or anything else for that matter—if you do not get the news of what you have to sell into the hands of the men who are most likely to be in need of them. We can do this for you through the medium of the Farmer advertising columns. How about giving them a trial?

* * *

It is a fine thing to have a farm named. It gives distinction to the place which tends to encourage a desire for community betterment and country life.

* * *

The boy with a calf, sheep or pig of his own today is the livestock amn of tomorrow—provided his father does not beat him out of the money the animal brings.

* * *

Pride never can learn fast or well. The way to knowledge and wisdom is through one's willingness to admit his ignorance.

CANADA'S TRADE OVERSEAS IN LIVE STOCK AND MEAT PRODUCTS

The Dominion Department of Agriculture has launched a vigorous campaign to secure for Canada a fair share of the trade developing in Great Britain and continental Europe for live stock and meat products and with this end in view Prof. H. S. Arkell, Live Stock Commissioner, has left again for overseas where he will spend probably several months on this mission. In this connection the following marketing policy of the Government was discussed and approved of at a meeting of representatives of the various live stock breeders' associations and the Provincial Departments of Agriculture.

1.—The Live Stock Commissioner, in connection with his mission overseas, has meen authorized by the Minister to negotiate with representatives of foreign Governments or through such other channels as may offer, with the view of facilitating the sale of our horses, cattle and other live stock and live stock products.

2.—He has been authorized to invite responsible parties from Canada to join him overseas, in order that business contracts may be immediately concluded.

3.—The Department of Agriculture through the Live Stock Branch, accepts the responsibility of recoginzing officially any companies proposing to do overseas business, the application of any company for such recognition to be approved by a committee consisting of the President of the Western Canada Live Stock Union, President of the Eastern Canada Live Stock Union, the Chairman of the Record Board, and the Live Stock Commissioner, or his accredited representative. The committee will give its approval after investigation of the company's busines integrity, financial standing and practical experience in the handling of live stock. It is to be understood that any company receiving such approval shall be entitled to recognition by the Department and to a share in any contract resulting from negotiations with purchasers overseas.

4.—Exporters desiring to obtain recognition by the Department for the above purpose not already incorporated shall be required to form themselves into companies and to secure incorporation under a Dominion or Provincial charter, in accordance with certain conditions as regards organization, which will be furnished on application.

5.—Any orders offered to Canada through negotiations with overseas purchasers shall be allocated for final contract to recognized companies by the committee named above.

6.—In the case of such orders the department will provide rigid inspection of all live stock exported by approved companies and the submission of their purchases to such inspection shall be imposed as a condition of the transaction.

7.—It is understood that the services of the Canadian Trade Mission in London will be available to facilitate financial arrangements. It is expected that it will be possivle to secure acceptance of stock by overseas purchasers f.o.b. Canadian ports and an effort will be made, so far as possible, to induce all overseas purchasers to send representatives to Canada with the authority to conclude contracts and advise with contracting parties in this country as regards the exact class of stock required and personally take acceptance of it at Canadian Atlantic ports.

8.—It is to be understood that the Department of Agriculture accept no commercial responsibility in connectoin with any contracts which may be concluded, but that it is arranging to furnish every assistance possible to approved Canadian companies in the securing of contracts.

9.—It is to be clearly understood that the foregoing does not interfere in any way with private trading.

The Situation Abroad

In opening the conference Prof. Arkell gave a review of his observations abroad in aMrch and April when he visited Great Britain and the continent, dealing rather minutely with each phase of the live stock industry, and incidentally pointing out that Canada had opportunities now in the development of trade which should be taken advantage of and necessarily would have to be provided if the country was going to go through its period of reconstruction with any marked degree of success both as regards finance and confidence.

Commencing with eggs and poultry he said there were 187,000,000 fewer fowl in Europe now than in 1913. Russia had been swept clean, France and Belgium reduced to the minimum, Denmark and Holland were shipping to Germany rather than the Allied countries, so that it was practically up to Canada and the States to tide over the situation. So far as American competition was concerned, he did not feel any need for alarm. Our eggs were being produced in a cooler climate, had a better body and texture, and were reaching the British consumer in better shape, and were therefore being given the preferenc. The development of this trade would mean an important revenue to the country.

Touching on bacon, he assured the meetinig that Canadian farmers could face the future with every degree of confidence. Statistics showed that the swine population of Denmark had been reduced from two and a half million to seven hundred thousand hogs, and moreover that due to force of circumstances or otherwise the export trade of Denmark and Holland was going to enemy countries. He warned those present that in his opinion it would be a mistake to try to develop a bacon trade in Europe, but that it would be much better to stick to the United Kingdom. The European market demanded a heavier, fatter hog than Canada had been producing, and for this reason the United States was in a better position to cater to that trade. He believed that Canada could now capture the bacon trade in England formerly held by Denmark, for the American bacon was not siutable for the British market—in fact it was held in disfavor there on account of being too fat and dry.

As regards horses the outlook was promising, there being two outlets, one in the United Kingdom and the other on the continent. In England there seemed to be an over supply of inferior horses but high class horses for agricultural use and transport service were scarce. The oportunity available to Canada to meet the requirements of the English market was all that could be desired but any stock sent over had to be right in every way. The English buyer demanded a horse 5 to 7 years old, in good condition, well mannered and broken 1,400 up to 2,000 pounds in weight, well bred, good action, clean limbs, absolutely sound and carrying a good middle. In France, Italy, Belgium, Poland, and the other Balkan countries horses were also in demand, a horse of much lighter weight meeting the requirements of most of these countries. The development of this trade abroad would tend to place the horse industry of Canada on a profitable basis again.

Coming to the beef cattle situation he felt that Canada had more to feel alarmed about than any other branch of the live stock industry. Both as regards price and quality Canadian producers had to face strong competition from Australian and the Argentine. During the war and since the Canadian packer had been introducing beef in the British market at 25c to 27c per pound, whereas beef much haevier and of much better quality could be purchased in the other two countries mentioned at around 11½c f.o.b. their ports. In view of this situation present prices could not be expected to continue in Canada and unless new channels opened up prices here would have to go down to a level with those prevailing in countries to the south where the cost of production was much lower than here. As regards Europe the outlook for a satisfactory market for beef was very uncertain on account of the policy bein gadopted to conserve as much as possible and the question of finances.

However one ray of hope in the United Kingdom was to be found in the fact that with the higher wages being paid labor it was only reasonable to expect that this class of people would become greater consumers of meat than heretofore and if this happened there might develop in time a demand for beef of the weight being bred, fed and marketed in Canada. Summing up the beef situation, Prof. Arkell said that sooner or later Canada might find herself in a difficult position to find a market for her beef catle unless she could develop a special trade for beef of light weight. Of course Great Britain needed more cattle and he felt that it might be worth Canada's effort to try and secure the removal of the embargo which was being favored by labor. Ireland was now finishing cattle rather than shipping them as stores and for this reason Scotch feeders were a little alarmed as to where they were going to get their stores.

The outlet for dairy cattle would be mostly in the direction of cows in milk and heifers bred. The price of wool would likely remain high and Great Britain would require lambs in the fall. There was a distinct shortage of butter and the price in Canada was fully justified as a result of the world situation. So far as cheese was concerned he felt that while there was a greater supply of it than happened to be in the case of butter, the demand was continuing to exist and that our prospects were as good in the open market as at a stated price.

Another Way Suggested

The whole matter being thrown open for discussion the feeling at first seemed to be that the Dominion Government should undertake the task of financing the proposition so as to insure the entire safeguarding of the farmer and seller here in Canada, ending finally in the following resolution:

"That we the representatives of the live stock production interests of Canada here assembled at the call of the Federal Minister of Agriculture, respectfully recommend to the said Minister that the Live Stock Branch of this department should endeavor to arrange, at the earlies possible date, for a definite sale of live stock (horses cattle or sheep, or any of these animals) to such Europeon countries as mae be in the markyt for the same, and with whom credits have been arranged.

"That the provincial departments of agriculture, co-operating with the live stock associations, arrange for the assembling of this stock at convenient marketing points within the respect-ve provinces, and that the Dominion Government make arrangements for the financing of such purchases.

"In the eyent of the Federal Department of Agriculture finding it impossible to bring European buyers to Canada to inspect and purchase such live stock, it is further recommended that the Federal Government arrange for the purchase and delivery to European markets of a substantial shipment of horses, cattle, sheep or any of these animals as a demonstration to these countriese of the classes of live stock available."

Later the above resolution was presented to the Acting Premier, Sir Thomas White, and the Minister of Agriculture, who pointed out that the Dominion Government was not in a position to and would not under any circumstances, undertake the financing of sending stock abroad, although it was prepared to advance credit to certain countries, Belgium having already been given credit to the extent of twenty-five million dollars.

The policy advocated by the meeting having failed to meet with the approval of the Government, the governmental offer was then taken up again and with a few minor changes, adopted, as indicated in the fore part of this article.

Want Embargo Off

Other resolutions passed by the meeting were:

"That we, the representatives of the live stock production interests of Canada, here assembled at the call of the Federal Minister of Agriculture, resolve, that in view of the importance of the cattle breeding industry of Canada, the embargo now existing against the importation of Canadian live stock into the United Kingdom should be removed, provided that a satisfactory guarantee be given to the British Board of Agriculture that Canadian cattle only will be exported.

"That the Department of Agriculture of the different provinces be asked to make a survey of their respective provinces for the purpose of ascertaining the numbers and classes of horses, cattle and sheep suitable and available for the proposed export trade.

"That this conference recommends to the Federal Miniister of Agriculture that representatives of the horse and catlle industry, one from western Canada and one from eastern Canada, be sent overseas to assist the Live Stock Commissioner in his negoiations for trade in Great Britain and Europe."

NEW RULES GOVERN EVERY LIVE STOCK YARD

On the recommendation of Hon. T. A. Crerar, Minister of Agriculture, new regulations relative to the operions of stockyards in Canada have been authorized by order-in-council. The regulations cover construction and equipment, operation and maintenance of stockyards, and their chief purpose is to provide improved connection with the handling of stock.

The regulations governing construction and equipment provide that every stockyard must be so equipped as to afford adequate accommodation for the transaction of business with safety and despatch. No subsequent alteration or addition shall be made to any stock yard until the approval of the minister has been obtained. Ample provision for the proper handling and feeding of live stock must be made, including a supply of running water.

Operation and maintenance regulations provide that live stock must be handled in such a way as to prevent injury or bruising. The proprietor shall see that no live stock suffers from want of feed or water while in his charge. In the case of live stock to be fed for maintenance only, the proprietor shall supply the amount of feed prescribed by the Live Stock Commissioner. Charges for feed and supplies for each calendar month shall be determined by adding to the wholesale market price for the preceding month a percentage plus a fixed charge for handling. The proprietor shall file with the minister not later than the tenth day of each month a statement of the average wholesale market price of feed and supplies during the preceding calendar month and a statement of the charges in force during the current month, suported by documentary evidence.

It is provided that acocmmodation shall always be given in preference to stock for storage. There shall be kept a register of all sales of live stock in such form as the minister may prescribe, and this shall be available for inspection by the public.

HORTICULTURE.

EFFECTS OF PRUNING ON THE TREE

The results that follow any kind of pruning are very complicated. Thus, a pruning given during winter or winter or spring may have the effect of reducing the yield next summer, but of increasing it the second after the pruning is done; or it may have the effect of reducing the yield during several years, but still be profitable because it prolongs the life of the tree. In pruning to shape the tree, the effect of a system of training adopted when the tree is young may not be known in a climate like that of New York for fifty years, even if the same system is followed during the life of the tree. Sor this reason, our knowledge concerning the best methods of pruning is very meager indeed. Thus, if we are to learn by experimenting what are the best methods of pruning, those experiments must extend through a very large proportion of the life of the tree, with the apple certainly thirty to fifty years in training experiments. None have been conducted through so long a period. For the same reason the experience of growers gives less conclusive guidance. In this locality would consider such practice, where the effects are more quickly seen.

On acocunt of this chaotic state of our knowledge, even what we do know with certainty about pruning does not seem to be made use of very generally in practice. It would seem, then, that a discussion of the subject of pruning in which what we know is carefully separated from what we must do without adequate knowledge as to what is the best method, would be well worth while.

Concerning the immediate effects of cutting away parts of the tree top in pruning, we can speak with more certainty than concerning the effect of any particular shape on the bearing of the tree. Thus, it is common knowledge among people who have had experience in pruning that cutting away part of the top of a tree during the dormant season increases the vigor and growth during the following season of adjacent twigs that are left. The new shoots will be longer, the canes larger, and growth will continue later in the season. It is also true that this new growth is generally stockier.

In spite of this increase in vigor, the effect of pruning is to reduce the total amount of growth. Although the growth following pruning is more vigorous there are fewer growing points. Not only is the new growth insufficient to replace what has been removed, but in actual fact less growth is made than on the unpruned tree. In other words, in case of two trees, one rather severely pruned and the other unpruned, the unpruned tree will be larger than the pruned tree by more than the amount of growth that has been removed from the pruned tree. The explanation of this is the fact that the pruning, by removing buds that would open into leaves, reduces the foliage. In our own pruning experiments, we have found a marked reduction in the total leaf surface of those trees that have been pruned with any degree of severity. When it is remembered that the material from which the entire tissue of the tree is built is elaborated in the foliage it will be seen that this reduction in growth would be expected to follow a reduction in foliage unless an improvement in the water supply or other conditions of growth should be associated with the pruning.

Thus, with some one-year-old apple trees in the nursery where the leaves were removed early in the summer to a height of about twenty inches on fifteen trees, at the end of the season the weight of the roots was 38% less and that of the tops 40% less than those of the unpruned trees that were no larger at the beginning of the experiment. It will be seen, then, that the foliage even on a branch that must come out later may be of value to the tree by increasing the growth of the roots and the size of the trunk.

Reduces Early Bearing

Not only does pruning reduce the size of the tree, but even more markedly it reduces the fruitfulness during the early years of the life of the tree. In the experiments done by Pickering, which are by far the most extensive in this line, the fruitfulness of severely pruned trees was reduced during the first fifteen years of the life of the tree by more than 100%. Of course, no one than with other phases of orchard severe pruning as Pickering was doing, but in our experiments we find that the relatively small amount of pruning necessary to shape a tree to an open head reduces the fruitfulness, at least during the first few years. In this pruning, few of the trees had more than two pounds of wood removed in a year, and yet the effect has been appreciably to dwarf the tree and to reduce the fruitfulness; though, of course, not to anything like so great an extent as when they were pruned as severely as Pickering pruned.

CULTIVATION DESTROYS PERENNIAL WEEDS

The successful eradication of weeds depends upon a knowledge of two important points. First, how long does the plant live and secondly, how does it reproduce and spread? With respect to the duration of life there are three classes of plants, annuals, biennials, and perennials. The first comes up from seed, bears flowers and seeds, and later dies; all within one year. A biennial grows from a seed but produces only leaves the first year. The root and sometimes the leaves live through the winter, but the second year a flower stock comes up, seeds are produced, and the plant dies. A perennial is one whose roots live year after year unless killed in some way, and the plant may or may not produce seed every year. Practically all an-

Nearly Two Centuries Old

Brandram's Genuine B-B White Lead

Do they not mean something to you,—these pictures? Look at them. A long and honorable history is behind them.

Canada was largely a wilderness when Brandram's Genuine B-B White Lead was first made. Napoleon has come and gone. The United States has come into being—and now Germany has fallen. Steam power, electricity, telephone, telegraph, wireless, submarines, airplanes—these have all come into being since the Brandram process was discovered.

1919 is using out of the same pail as 1745? Exactly the same process was used in making the white lead (Brandram's Genuine B-B) of 1745, as is used in making that of 1919. In the world competition which has been waged all these years, the Brandram process is the only survivor of all the white lead processes which were in use at the time it came into being.

This is the white lead which is used in B-H "English" Paint, and in all other Brandram-Henderson paint products employing a white base.

Your guarantee lies in that two centuries of history. No one else can give a guarantee of the same character

nual plants reproduce themselves by seed only. Biennials also, except for the one winter through which the roots live, reproduce themselves by seeds. Perennials may propogate by means of the roots as well as from seeds. The importance of knowing the habits of any weed lies in applying this knowledge to eradicaton of the plant. For instance, it would be useless to summer-fallow a field in order to kill an annual weed like the wild mustard which can be kept from spreading by any method that will prevent it from bearing seed. On the other hand it would be equally unwise to attempt to control quack grass by preventing it from bearing seeds since in many cases it is propagated from root stocks.

The control of annual and biennial plants call for practically the same treatment, namely preventing them from bearing seeds, but perennials must be treated in an entirely different way. Therefore, in view of the fact that Central Canada is more or less troubled with perennial weeds the Maritme Farmer has deemed it advisable to discuss a few of the more prevalent of these. Although there are many perennial weeds and possibly some more serious ones, the most common are quack grass, perennial sow thistle and Ox-eye Daisy.

Quack grass is a tall growing grass with fine fibrous roots as well as underground stems or root stocks which give this plant its noxious character. These underground stems are nearly white and the joints are close together, usually not more than one inch and often less. At each joint new roots are thrown out and at many of them new stems start. In this way the grass spreads rapidly and a piece of the root stock with one of these joints on it will produce a new plant although it may be not over one-half inch long. It ripens its seed in July and unless cut before that time it will be gathered in as hay or in the grain and is bound to spread by the seeds finding their way back to the land, either in manrue, or seed grain.

Perennial Sow Thistle is a tall, coarse growing perennial weed with deep roots and numerous thick underground stems, or root stocks, commonly spoken of as "roots." Upon these, at intervals of a few inches, are borne buds which develop into new plants. The stems are smooth and hollow, and the whole plant is filled with a bitter milky juice. The leaves are pointed, 4 to 12 inches long, deeply cut with segments pointing backwards, and the flowers are abot 1 to 1½ inches across, and bright orange in color. It is rapidly and widely spread by means of its numerous seeds, which are blown around by the wind, and also by its abundant root stocks, which produce a plant every few inches. If these roots are cut or broken each piece then sends up a plant, and the result is that there are now two plants where there were only one before.

Ox-eye Daisy is a shallow rooted plant with numerous stems, simple, and branched and growing to a height of from 1 to 3 feet. The flower heads are solitary on long, naked stems 1½ to 2 inches across, with 20 to 30 rays to each flower, and are pure white with a yellow centre. A single plant produces from 5,000 to 8,000 seeds in a year.

Eradication

Many methods have been devised and advocated for the eradication of these perennial weeds; but the success of any method depends largely upon the soil, weather conditions, and the thoroughness with which it is done. Quack Grass is more persistent and more difficult to eradicate than either of the other two, hence any method which will eradicate Quack will surely destroy the others.

The field should be ploughed shallow as soon after the hay crop is removed as possible and cultivated with a spring-tooth cultivator, drag harrow, or similar implement that will bring the roots to the surface. A disk harrow is not satisfactory, because it buries the roots rather than leaving them exposed to the sun. This cultivation should continue at intervals throughout the summer and fall till most of the roots are brought to the surface and dried. They may be then raked up removed, and burned, or thrown into small piles in the field and burned there. The field should be ploughed again either late in the fall or early next spring and after a thorough cultivation planted to corn, preferably in thick rows, and cultivated throughout the summer. If the field is extremely dirty another hoed crop may be necessary the following year, after which it should be sown to grain and seeded down. This method entails a lot of work, but no crop is missed and the after harvest culfivations put the soil in better tilth, thereby producing a better crop as well as cleaning out the weeds.

Grow Strawberries for Profit

Do you know that one Farmer in New Brunswick sold nearly $5000 worth of berries from five Acres? That another Farmer sold over $8000 worth from a little over ten acres? These results are not exceptional, any good farmer can do as well who will give his attention to the most profitable crop that can be grown in the Maritime Provinces. We can supply Plants for the professional Strawberry Grower, for the man who grows an acre or two as a side line to general farming or for the family garden. Good strong well rooted plants are more than half the battle in successful strawberry culture. Start right. Don't take plants from an old bed or from the side of the rows as a gift. All Farmers know that poor seed means a poor crop. Dunlaps, Warfields and Beder Woods, $4.00 a thousand; Sample, Glen Mary and Dr. Burrell, five dollars a thousand.

Butter Parchment at Farmer Office

DAIRYING

THE MILKING MACHINE

(By Geo. W. Muir, B.S.A., Assistant to Dominion Animal Husbandman, Ottawa.)

The object of this circular is to put before the dairy farmer the value of the mechanical milker under the present conditions of labor on the farm.

There has been in the minds of many dairy farmers a great deal of prejudice against the use of a mechanical milker, but the present is no time to let prejudice stand in the way of increased production.

Every dairy farmer with a herd of 12 or more cows should consider seriousIf the installation of a milking machine.

The experience of an ever increasing number of practical farmers, coupled with that of a number of our Experimental Farms and Stations, goes to prove that these machines are decidedly advantageous.

Cost of Installation

The average cost of installation, taking into consideration the five most popular machines on the market, would be $5.00 for an outfit to milk four cows at once.

Such an outfit would be large enough for a 25 to 35cow herd.

For a 20-cow herd a 3-cow outfit would be sufficient. For a 12 to 15-cow herd a 3-cow outfit would be sufficient.

For each reduction of one unit in the installation there will be a reduction of approximately $100 in the cost price.

This brings the average cost price to $16.60 per cow for the large herd; $20 per cow for the medium sized herd; $25 per cow for the small herd.

This in turn goes to show that whlie the cheapest installation for work done is with the large herd, nevertheless the first cost is not excessive in the case of a small herd.

Cost of Operation

The annual cost of operatiion for a 25 to 35-cow outfit, including repairs power, labor in caring for engine and washing machines, interes on investment, and ten per cent. depreciation on machine, would amount to approximately $225.

The above is approximately one-third of what the farmer is at present paying his hired man, where board is not take ninto account.

Divided between 30 cows, this brings the running expenses to two cents per cow per day.

Above Cost Compared with Cost of Hand-Milking

The average hired man will not milk more than seven cows per hour, which at 25 cents per hour, costs 7.2 cents per cow for hand-milking.

One man with a milking machine can milk 20 to 25 cows per hour, which brings the total cost of machine milking including the above mentioned daily running expenses, to 4. cents per cow per day.

This is a saving of considerably over one-third and in a large herd would enable the farmer to dispense with at least one, if not two, men, or it would liberate these men for other important lines of increased production.

It also enables one man to milk many more cows than it is physically possible for him to miilk by hand.

Uniformity in Milking

Not only does a machine deecrease the cost of milking ,but it gives uniformity in milking.

All cows are milked in the same manner every day, and every good farmer knows this is important and that it is hard to obtain with the general run of farm hands.

Reliability of Service

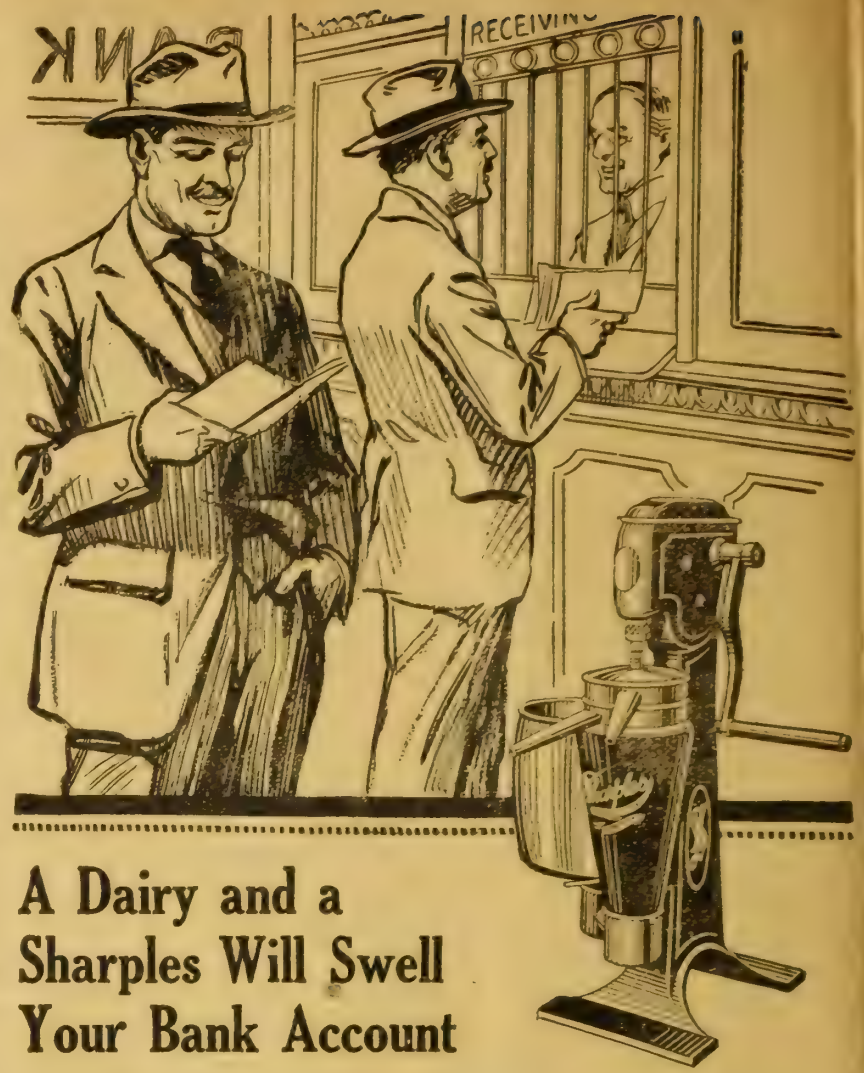
A machine when properly installed and equipped with a reliable source of power is always there ready for work.

Breakdowns are comparatively rare and usually easily remedied.

Wear and tear is not excessive, considering the nature of the machine, and provided the latter is given proper attention.

Effect on Cows

A machine that is properly adjusted and handled will not injure the cows' teats or udder any more than the av-



A Dairy and a Sharples Will Swell Your Bank Account

The reason is simple. You know how profitable a dairy *ought* to be—but perhaps you do not realize how greatly a Sharples increases your profits. Sharples is a *Suction-Feed* separator—all other separators are fixed feed. Now get this: Sharples can be turned at any speed and it *skims* clean. Fixed feed separators when turned *below* speed marked on the handle cannot skim clean—as the flow of milk is greater than the separative force. Some owners of fixed feed separators boast that they always turn at the right speed, but thousands of individual tests prove that fixed feed separators lose butterfat ninety-nine times out of a hundred. There is only one sure way to skim clean all the time at all speeds and under all conditions—use a

SHARPLES SUCTION-FEED CREAM SEPARATOR

Fatten up your bank account *right now* with a Sharples. Write for literature that tells you how to do it. Your family will also enjoy the Sharples Book of Old Songs. It's free. Write to nearest branch, addressing Dept. 79

Over 2,425,000 Sharples Separators in Daily Use DC-84

erage farm hand.

Three years' experience of mechanical milkers on the Central Experimental Farm does not show that the cows dry off any more quickly than when milked by hand.

There is no more, if as much, objection to the milking machine on the part of the cows than there is to hand milking.

Old cows used to hand-milking object most, and may not let down their milk readily, but heifers take to machine milking like ducks to water and require hardly any stripping.

AS RELIABLE AS ITS NAME

"Received your churn safely and gave it a fair test; I am perfectly delighted with it," writes one recent purchaser of a "Reliable" Churn—and there is a reason.

You get your butter the easiest, quickest and most profitable way, when you use

THE FAMOUS

RELIABLE CHURN

Its clever mechanism gives that efficient perpendicular stroke, but with a high-geared rotary drive, and it is easier to keep clean, too, just lift out the smooth, white, double glazed jar and rinse.

You can get a book which illustrates every part, gives you full information of hand drive (which can be operated by a child of six,) belt drive and electric drive Reliable Churns.

A POSTCARD WILL DO—WRITE NOW WHILE YOU ARE INTERESTED

GLOBE ENGINEERING CO. LIMITED HAMILTON, CANADA.

Stripping by hand after taking the machines off is advocated by all users, as well as makers, as a precautionary and economical measure.

Effect on Quality of Milk

If the machines are properly handled in the barn, and likewise properly washed in the dairy, the milk produced will be as good, or better, than that produced by hand-milking.

When extra pains are taken with the machines and the care of the milk a very high grade of milk can be produced.

Careless handling results in bad milk and ultimate failure of the machine.

Importance of Efficieincy in Operation

Last, and of far more importance than the cost price or make of the machine, comes the question of the efficiency of the operator.

Handling the machine is a job for the farmer, his son, or some hired man who has an interest in the success of the machine and the cows.

For the best results the operator must be quick and quiet, with an eye for details.

Know the machine and the cows and adapt the one to suit the other, giving each their proper sare of attention at the proper time.

Makes of Machines

Any of the more prominent makes of milking machines upon the market will do good work, provided they are properly handled.

The addresses of the dealers or manufacturers of the various machines can be procured from farm journals, or upon aplication to the Animal Husbandry Division, Experimental Farm, Ottawa.

INCREASE PROFITS IN DAIRYING THROUGH BREEDING BETTER COWS

Heavy and economical production of milk is largeely a matter of individuality in cows, and by that we mean that some cows have the power to make use economically of much larger quantities of feed than others. All cows require about the same quantity of food for maintenance. Above what a cow requires for maintenance, she uses either for milk production, or body fat. Cows that are low producers of milk tend to laying on fat with the excess feed they eat above the maintenance supply, whereas cows of the pronounced dairy tendencies will not take on fat, but will produce with it the supply of milk. From a strictly dairy point of view, feeding these two animals the same quantities is a distinct loss to the farmer. It takes all the profits their heavy milking cows make, to make up for the waste of feed occasioned by keeping the low producing cows. Herein lies the skill in feeding that is based every time, on the individuality of the cow. Without the full knowledge of the milk producing propensities of every cow on the farm it is impossible to tell if the milk production is a paying proposition.

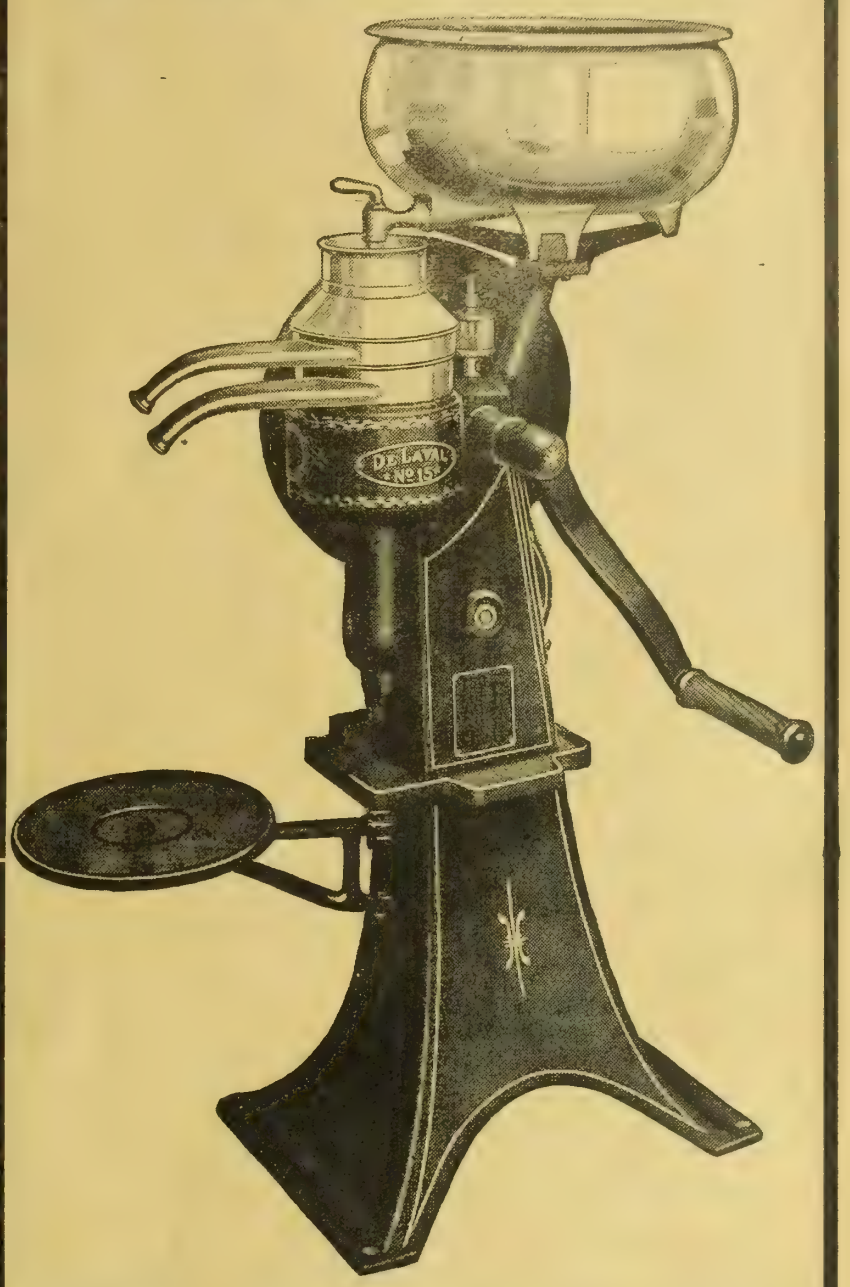
Why is it that on one farm the average yield of milk per cow is 6,000 pounds, and on a neighboring farm 3,000 pounds per cow? Why is it that on one farm the average yiield of potatoes is 300 bushels and the farmer next door gets only 100 bushels per acre? It is the difference in the individual. Both lands were of the same quality, and both cows had used the same quantity and quality of feeds.

Who Steals the Profits?

Therefore, what is wanted in the production of milk, both for sufficient quantity and with a sufficient mar gin of profit left the dairyman, is the elimination of the low producing cow. She stands between the farmer and the consumer as a bugbenr on his industry, drawing upon the profits of his high producing cows, camouflaging her real position of feed waster and profit stealer.

Continued on page 960)

Now is the best time to buy a DE LAVAL CREAM SEPARATOR



THESE are the days when the farmer is getting the most milk, and with butterfat at its present high price he should be sure to get all the cream.

Many "claims" are made for various cream separators, but the most convincing proof that the De Laval is the cleanest skimming machine is the fact that 98% of the large creameries the world over use the De Laval.

Even if you do not separate as much cream as the large creameryman, you can no more afford to waste cream than he can.

THE TUBERCULIN TEST IN CATTLE.—SOME FACTS BREEDERS WILL DO WELL TO CONSIDER WHEN TESTING

Is the tuberculin test anywhere near a sure thing? Are cattle that react sure to be diseased, or will they react sometimes when there is nothing wrong? Will cows due to calve in a few weeks' time react when free from tuberculosis Will cows that are free from the disease react just after calving Are there any causes that will make cattle react when free from disease Are some breeds of cattle more apt to have tuberculosis than others?

The tuberculin test is just like anything else. It is not infallible, and its work is determined very largely by the efficiency, honesty and commonsense methods by which it is applied. Cattle that show typical reactions are quite sure to be diseased, provided conditions under which they are tested are normal. Many veterinarians claim that because a cow is shortly due to calve, or because she has very recently calved need not be considered in administering the test. This may be true; but if a cow under either of these conditions or under abnormal conditions shows a reaction, she should be considered merely suspicious. Then she should be isolated from the remainder of the herd for not less than 60 days, and re-tested to make sure. Any condition that causes a cow to be in a feverish condition, is liable to render the test doubtful. It is but good common sense to recognize this, and give the cow the favor of the doubt as suggested above. Whenever a large percentage of a herd reacts, the owner should follow the cattle to the butcher. If tuberculosis is present the veterinarian can point out the lesions, proving the accuracy of the test. The accuracy of the test intelligently applied, with the use of a liberal amount of common sense, is not to be questioned. In accuracy is more to be feared from the standpoint of failure to detect the chronic case. Quite often cows far advanced in the stages of tuberculosis will fail to react to the test, and by being left in the herd they continue to infect healthy animals. Breeders will do well to consider this fact, rather than to doubt the accuracy of the test on the other hand.

The dishonest veterinarian who misreads the test, and deceives his client by making him believe that his herd is entirely healthy when there are reactors present, is far more to be avoided than the one who is so overly strict that he occasionally condemns a healthy animal. The honest veterinarian who uses common sense and efficiency is a benefactor to the community he serves. Such—and only such—a representative of the veterinarian profession should be permitted to even live in a community. All others should be ostracized. Then—and only then—will there cease to be doubters of the tuberculin test.

All breeds of cattle are susecptible to tuberculosis. No one breed can be considered more susceptible than another. It is not a question of breed. It is a question of tubercular germs being present, and especially in barns that are poorly ventilated, dark and damp. It is very largely a question of foolishly refusing to permit foul air to leave and fresh air and sunshine to enter the cow's barn.

Particular breeds of cattle are not more susceptible to tuberculosis than other breeds. No matter what breed a cow belongs to, no matter how big and strong of constitution she may be, she will get tuberculosis if she is subjected to tuberculosis germs, and it won't take long if she is kept in a dark, damp, foul barn where there is little light and fresh air.

The Model Kitchen

Everything up-to-date—especially the stove—the most important part of the kitchen equipment. That is why the successful housewife chooses the New Perfection, the oil stove that saves time, labor and worry—that cooks all recipes to the height of Perfection.

The Long Blue Chimney Burner on every stove makes clean intense heat. It concentrates it all directly under the utensil—none wasted. And because the combustion is perfect there is no smoke or odor.

The New Perfection does everything a gas stove does—is as easy to regulate. 3,000,000 are now giving satisfaction to just so many housewives.

A REMEDY FOR STERILITY IN COWS.—PRINCIPLES UNDERLYING THE DISEASE.

I have read with much interest the information on contagious abortion which has lately appeared in your columns and would like to get your opinion about the cause of sterility, or cows failing to prove in calf though berd repeatedly, a circumstance that is causing loss in many herds today. Is this due to the presence of contagious abortion?

There are many erroneous ideas about barrenness, the commonest being that the animal is not open. Contrary to the genital structure of a mare, that of a cow cannot be tampered with by any artificial "opening." Any attempt to operate on a cow in order to make her conceive is bound to result in failure or may end in the death of the animal. Likewise breeding powders, and similar preparations or concoctins administered into the genitals, or given in any other manner will not overcome the diseased condition of the genitals, which is largely responsible for sterility. Barrenness is a common sequel of contagious abortion as either the abortion germ or the germs that enter the uterus as a result of retained afterbirth are capable of maintaining the uterus in a serious state of ill health. Other condition, in addition to infection of the genitals, that are responsible for barrenness are diseased

and have the barn door hang and run right for all time. This is positively the finest Barn Door Hanger on the market. As its name implies, birds cannot build in the track. The track is hollow with closed ends. No ice or snow in winter or trash in summer can possibly get in to clog it. Runs on two strongly braced roller bearing trolley wheels, always smooth and easy running. Hinged so as to make it flexible and to allow the door to swing outwards and upwards if occasion requires.

DEMAND REMOVAL OF CATTLE EMBARGO

The Scottish Chamber of Agriculture recently held several meetings to discuss the question of the embargo on Canadian cattlee, and by a substantial majority the directors have decided to demand that the embargo be removed. At the meeting where the final resolution was adopted the president of the chamber made some pointed observations on present conditions between Scotland and Canada. He scaid: "Canada has for the moment completely shut out Scottish cattle from the Dominion, though there is no disease in Scoltand, nor ha sthere been for many years. This leaves a somewhat nasty taste in the mouth when we, in Scotland, proceed to consider the matter of admitting Canadian cattle. The wrong-doing, if wrong-doing it is to be celled, is not all on one side. Let both sides play the game, or not play at all. If Canada is free from disease, so is Scotland, and until Canada lifts the embargo on our cattle, the question of admitting Canadian stock to Scotland must necessarily lie over. And if there are to be open ports, let the conditions be alike. If there are to be quarantine and test regulations on the one sidefi let the same hold good on the other. No doubt a substantial period of quarantine might reduce the risk of admitting live cattle from other countries to a minimum, but, of course, in the interests of the valuable breeding stocks of this country there must be no risks."

A TONIC FOR ALL LIVESTOCK

Stock of all kidns need salt. Experiments with milk cows have often showed that there is an increase in the milk production when salt is added to the ration, and a decrease when salt is taken away. Chickens and fowls of all kinds reslish an occasional pinch of salt in their ration, while the need is equally great with the horse.

Ecpecially in pig culture salt, charcoal and ashes are great aids in promoting bone growth as well as to correct acidity of the digestive organs and prevent worms. In saving ashes for hogs we always rake in as much of the charcoal as we can. Some farmers mix sulphur and copperas with the ashes, but others prefer to give these drugs in slop, unless animals are readily sick and require individual treatment. In the latter case those that are serious should be kept separated from the herd, and the medicine administered according to directions.

SELECTION OF STOCK

The inexperienced sheep raiser should begin with grade ewes of the best class available and a pure-bred ram. The raising of pure-bred stock and the selling of breeding rams can best be undertaken by persons experienced in sheep-raising. The selection of the type and breed should be made by considering the class of pasture and feeds available and the general system of farming to be followed, along with the peculiarities of the breeds and condition and kind of feeding and management for which each has been especially developed.

Install an IDEAL SILO now!
It will pay its own cost quicker than ever before

Thousands of Ideal Green Feed Silos have earned their own cost the first year on Canadian farms.

But an Ideal erected on your place this summer will pay for itself in less time than ever before. Why?

Because it will greatly reduce the amount of dry feed you'll have to provide for your stock next winter—and mill and grain feeds are higher than in many years.

And because it will enable your cows to give 20 to 25 per cent more milk—and butter-fat is bringing 50 to 60 cents a pound, as against 20 to 30 cents in other years.

Figure it out.

Write today for our illustrated silo catalogue. You've no time to lose if you hope to get your silo erected in time to take care of your 1919 corn crop.

MONTREAL PETERBORO WINNIPEG VANCOUVER

GOOD NEWS FOR MARITIME STOCK MEN

Some weeks ago it was announuced through the Press that a strong movement was afoot, originating with the Maritime Stock Breeders' Association, to secure Federal aid in providing cold storage and marketing facilities at one of our eastern ports. This implied also the erection of stock yards and abattoir, not necessarily at the same point, but in a convenient locality for the whole area.

An expert was sent down from Ottawa to look over the whole situation and report. His report is a most favorable one, and the request has now come from Ottawa to the Maritime stock interests to select the location for the stock yards and abbatoir. It is taken for granted that the best point for the cold storage and shipping plant is Halifax.

A meeting is now being called at Amherst on the 17th June to decide this matter. It is hoped that all parts of the territory will be presented and an amicable and wise decision will be arrived at. In the meantime the men who have been pushing the whole enterprise are to be congratulated on the prospect of success.

A calf should not have more than two gallons of milk a day—this will be about 20 younds. Of course, when he grows older he may handle as much as 25 pounds per day. Start the calf out with not more than one gallon or eight pounds per day during the first week. This may be increased to 10 pounds the second week; 12 the third week and 14 the fourth week. The feeder must watch the calf and see just how he is thriving. The most important point in feeding a calf is that the amount of milk fed should be uniform—not a great big feed in the morning and a small feed at night, or vice versa.

Calcium and phosphorus, the two most important minerals required by swine may be supplied by feeding bone meal, wood ashes, corn cob meal or charcoal. These two elements are especially deficient in corn, seeds, cereals and cereal produces. Skimmilk and tankage occupy first place sa sources of mineral nutrients for the grain fed hog.

No animal appreciates sunshine more than young lambs. To shut them away from it is cruel and unprofitable. Any ailing sheep or lamb or sheep and lambs, for any reason shut away from the main flock will always eeat better and do better if allowed a sunny yard during a part of the day.

A good way to teach a young calf to eat grain is to take a little of the grain the hand and place it to the nose and mouth of the calf immediately after he gets done drinking. This grain will adhere to the moist surface causing a ticklinsh sensation, and the calf immediately begins to lick the grain into his mouth. In this way he gets a start. If there is a little fresh grain in the manger he wil son begin to nibble at it himself.

THE BEST LINIMENT

OR PAIN KILLER FOR THE HUMAN BODY

Gombault's

Caustic Balsam

IT HAS NO EQUAL

For the Human Body — It is penetrating, soothing and healing, and for all Old Sores, Bruises or Wounds, Felons, exterior Cancers, Boils, Corns and Bunions, CAUSTIC BALSAM has no equal as a Liniment.

We would say to all who buy it that it does not contain a particle of poisonous substance and therefore no harm can result from its external use. Persistent, thorough use will cure many old or chronic ailments and it can be used on any case that requires an outward application with perfect safety.

THE HORSE

THE DANGER OF FEEDING MUSTY AND INFERIOR HAY OR GRAIN TO FARM HORSES

Ill fares the horse that is fated to become the dump for all inferior hay or other feed stuffs during the comparative idle days of winter. Because the horse is not doing much many farmers think they are economizing by continuing this practice. There are no farm animals whose organs are adjusted by nature to digest feed that has been badly handled in harvesting or storage, and the horse is the most sensitive of all to its evil effects. Evidently it is considered economy to make the horse the open sesame for such hay as has been spoiled. "It will do for the horses," is a common remark, and the manger is filled to the full and the horse is supposed to pick out the best of it.

I visited a farm some time ago where this practice was in force and it was put down as "economy" in feed. There were 15 cows in another barn—an average bunch of the 4,000 to 6,000 pounder type—and they were receiving all the best clover hay and concentrates they could eat up. The arrangemeent was a continuation of the economy idea, and readers can judge the results of a few years' practice at throwing away expensive feeds on cows that were not paying for it; and starving the horse that supplied the motive power required to carry on this non-paying business. But this is a digression from the fate of the "economized" horse.

Risks Taken in Feeding Inferior Hay

No farmer can help, some years, in having more or less spoiled hay, caused either by wet weather, overripe sunburned timothy or scarcity of labor. And what to do with it is a problem, but it is very risky feeding t ogive horses. In my experience in Scotland, in feeding horses where the climate is so much against the making of good quality of hay, I found that well harvested oat straw made a more superior and safe feeding. Oat straw, when the crop is cut before it becomes too ripe, is far better feed for horses, in my estimation, than over ripe fibrrous timothy hay that is so often fed to them. The oat straw also had the advantage of being free from dust, as all the threshers used in Scotland put the straw through a fanning mill, separating dust, chaff, weed seeds and similar rubbish, while moldy, fibrous hay retains all its objectionable features.

It is the unmarketable hay that is generally kept for the farm horse, and unfavorable harvesting seasons are followed by much sickness in the stables. The horse's stomach is a comparatively small organ, and it is very unwise to overload it any time, but more especially if the feed is of inferior quality. Bulky feed of poor quality deranges the digestion, lessens energy, interferes with the functions of the lungs and endangers life.

The absence of colicky pains that may follow the eating of moldy hay by some horses is no criterion that the horse is not suffering, or that his usefulness is remaining unimpaired. His digestive organs are being highly taxed all the time and digestion is weakened, and the horse is losing energy and flesh. There is a mistaken idea that a grain ration given will tone up the inferior hay. It will certainly help to keep the horse in better vigor and flesh, but it will never allay the evil effects of feeding large quuantities of inferior fodder, and the full benefit of a grain ration is lost when fed along with dusty or moldy hay.

How to Diminish the Risks

If the hay supply is such around the barn that no other can be had than that which has been somewhat spoiled, its condition can be improved so as to avert some of the baneful effects. Shaking the hay to remove the dust before feeding is always a safe procedure as well as dampening it after the shaking. Lime water is one of the best solutions to dampen the hay with. It is prepared by slaking the lime in water in some large vessel and allowing the lime to precipitate to the bottom, then using the clear water on top to dampen the hay. If this practice was followed there would be less cases of heaves, a malady among horses that follows in the wake of bad hay harvesting seasons, and feeding horses dusty hay under ordinary conditions of hay feeding in the spring time.

The care in feeding clean, fresh good quality hay must also be carried out with the other feeds as well. Damaged grain and grain largely made up of weed seeds are equally as detrimental to the health of horses. So also are the roots that have molded or heated in the cellars. Neither grain or roots that are spoiled should be fed to horses under any circumstances. They are even of doubtful value to the cow or the steer, but the anatomy of this species of farm animal can withstand much more than the horse.

Suitable Mangers and Feed Boxes

With the endeavor to get the best of feed to the horse there must also be exercised a watchful care in not wasting it. Many mangers and feed boxes are so crudely arranged that waste can be written in large letters over them in describing their use. The man who feeds his horses poor

You Can Control the Harvest

WHILE you cannot altogether control the size and quality of your grain crop you can control the harvest. For years you have been cheerfully complying with Government request to save materials by repairing your old machines rather than making replacements. Now that the need for this has passed, would it not be real economy to buy new machines and be assured of uninterrupted service at a time when a break-down would mean serious embarrassment and loss.

Deering and McCormick Harvesting Machines

save your crop when it is down, tangled or otherwise in bad shape. They give you a clean, good, cheap and always dependable job.

There is no better time than now to see the local agent about your binder, and to place your order for Deering or McCormick binder twine.

Our organization being an essential industry has been speeded to top-notch efficiency. By anticipating your needs and ordering early, you make it easier for us to take back our soldier boys without disturbing our present organization.

Deering and McCormick binders give service always and get service always. The service you get is such as you might expect from an organization that for nearly a century has specialized on farm needs. Write us for catalogues.

hay generally does it too generously, and the horse in searching for some of it that is palatable, tosses the most of it out of the manger in the operation, and it goes for bedding. The horse has therefore been taught the trick, and when he gets good hay it is subjected to the same treatment. Over head racks have the same wasteful fault. Most horses are fed too much hay rather than too little. Mangers built just a little extra deep are money-savers, for the horses cannot throw out so much hay.

Feed boxes for the grain are on the average too small. Nine out of every ten feed boxes around the stables are so small and shallow that no one can blame the horse for spilling the feed. The very operation in feeding by the horse wastes about one-fourth of the feed. It is spilled into the manger and on the stable floor. It may not be altogether lost in the manger, if it does not fall on to six inches of dust and weed seeds that are often allowed to gather there. Anyway the feed box is the place intended, and a proper one should be supplied. It is poor economy to fail to provide a proper feed box. It is the normal thing for horses to shove and throw their feed about with their noses while feeding. The spilling operation going on three times a day for a whole year, soon runs into money at the price grain is at present. It is rank waste at any time, and remodelling the feed boxes is the only way to cure it.

Curing the Horse that Gulps His Feed

Have the feed box from which the grain is fed at least 18 inches long, 15 inches wide, and 15 inches deep. Build such a box into one end of the manger, so that the top of the box is level with the top of the manger. This may shorten the manger but on the average mangers are apt to be too large, inducing the feeding of too much hay.

This arrangement may not totally eliminate waste of grain, for there are exceptional horses, but as a rule it will, for when the horse once gets his head into a feed box of this depth he will not manage to force the grain so readily as from a shallow box.

However, some horses have the habit of taking a large mouthful and then droping part of it on the floor at his feet. I have successfully stopped this, in many cases, by putting 2 or 3 smooth stones about the size of an apple in the bottom of the box, before pouring the grain over them. Horses that take big mouthfuls, and do not take time to masticate their feed or are liable to choke in their hunger and hurry, will be prevented by using a few smooth stones in the bottom of the feed box.

Winter is the opportune time to see after this detail in horse management. There are many idle moments in which to adjust the feed boxes, which operation, when completed with a little attention to the quality of the hay and other feeds given, will conserve the desired motive power for spring work, and save many veterinary bills.

THE INFLUENCE THAT PROPER ATTENTION OF BROOD MARE HAS ON THE HORSE INDUSTRY

Under ordinary conditions spring is the natural time for the young foals to arrive. Much of the success that attends horse breeding opertaions is due to the care and management of the brood mare. This care will aid her to produce a strong, healthy foal and will also fortify her own condition to raise it to full vigor. It has been made clear from time to time in these columns that the scientific study of the problems of breeding possesses a great national interest, but the success of these depend on the management of the pregnant female. It is obvious that any means by which disease and accidents connected with breeding can be checked, and the capacity to bear young of the most approved types, is of great commercial value.

Feed and Exercise

The brood mare that is sucking a foal or developing a foetus, should get feeds that correspond closely to those required by a growing animal. In view of the large amount of nourishment that the growing foetus requires, foods for the mother must contain a considerable amount of protein, and in order that her system be kept in good physical bloom, these feeds should have a cooling effect. Feeds which meet these requirements well are oats and bran. The bran keeps the bowels open and tends to keep the body and legs free from skin diseases. Roots, when they are available, form a very valuable addition to the ration, if fed in limited quantities. The amount of grain that a brood mare requires is about one pound to every 100 pounds of live weight, with about the same amount of good fresh mixed clover hay. In order to keep her doing well, she will need considerable exercise, for it is impossible to feed her as heavily as the above ration, and keep her in condition without exercise. There is however, the happy medium in balancing the feeding and exercise.

Some farmers never take any particular thought about the brood mare, and work her as they do an ordinary gelding. But they are taking great risks in doing so. Some hardy mares may pull through without an accident, but it is at a loss to the young foal, and will have a detrimental effect on its life history. **Doing team work in the wabon, ff there is much backing to be done, is bad practice. A brood mare should never be called upon to do this class of work.** Again on the other hand, there is as much danger ger of a lack of exercise, and the most experienced and successful horse breeders are the farmers that work their mares judiciously and regularly up to the time of their partri- tion.

At the Time of Foaling

The mare carries her foal about eleven months, but living foals may be born at ten and a half months to a year. **Between the sixth and eighth months they are most liable to cast or abort the foetus, if put to too heavy work on wet and heavy land, especially as one of a team in a wagon.** Every care should be taken at this period that they are not unduly strained at work.

Before foaling, the udder becomes filled, is hard, and sometimes tender. The pelvic ligaments become slackened as can be seen in the depressions at each side of the tail. Generally some wax shows at the point of the teat, or milk may escape from the teat for a considerable time before foaling. None of these indicate the exact time that parturition will take place. It is impossible to tell the exact period. Parturition comes on very quickly, often without warning,

POULTRY.

COTTON SEED MEAL AS A POULTRY FEED

(By B. .F. Kaupp, North Carolina Experiment Station.)

Work on several series of evperiments conducted over a period of five years at the North Carolina Experiment Station, have recently been completed. The following summary and conclusions seem justified at this time.

Cotton seed meal contains a substance called gossypol. This gossypol contains two pigments, one a brownish resinous substance, and another a yellowish crystalizable substance.

The pigment of gossypol is stored to a more or less extent in the fat and in the yolks of eggs by those hens consuming the meal. Some hens have a tendency to store more than others. These brownish-yellow yolks are objectionable to the consumers, though they are perfestly wholesome so far as our knowledge goes, but are thought to be spoilt by the consumer.

Gossypol to the amount contained in one ounce of cotton seed meal, consumed daily by adult fowls, produces injurious effects as pedulous crops, depraved appetite, the latter leading to the eating of sticks and pieces of litter as straw, resulting in impaction and death of the fowl.

If the total feed consumed consists of 30 per cent. cotton-seed meal, there is likely to be ill effects and some deaths due to the meal.

If the cotton seed meal be given in the mash alone, and the birds are given a morning and evening scratch feed and in addition allowed more or less range so that they can forage an additional amount of feed, it will be noted that the effects are not nearly so bad from the fact that if they get sick of the cotton seed meal they will have a chance to "lay off" for a while and later return to it. That, in our estimation, partly acocunts for the different opinions given on the feeding of cotton seed meal.

Birds eating excessive amounts of cotton-seed meal or its gossypol, apparently die from emaciation and starvation owing to the fact that they refuse feed.

Twenty per cent. cotton-seed meal in broiler fattening proved satisfactory, and likewise the same results obtained in cram feeding work of old hens.

In two of the three-year feed tests the highest percentage of deaths was from cotton-seed meal lots (pens 23 and 36). It is generally conceded that a high percentage of cotton-seed meal and of linseed meal cause a higher death rate than many of the other concentrates.

There are marked differences in individuals as to their tolerance of cotton-seed meal. Heating the cotton-seed meal to a high temperature has a tendency to lessen its injurious effects.

The feeding of large amounts of cotton-seed meal has no ill effcet upon the progeny of those birds fed on it.

Cotton-seed meal fed to young chicks in quantities not to exceed 10 per cent. of the mash has given good results.

Cotton-seed meal is high in globulin, a protein stimulative to growth and development, also in alkali-soluble protein likewise stimulative to growth.

The limit of safety in feeding cottonseed meal for all purposes to fowls is perhaps about 10 per cent. in mash, allowing the birds grain feed twice daily in addition.

(Cotton-seed meal is a good thing to let alone if other feeds are available.—H. B.)

LET a woman ease your suffering. I want you to write, and let me tell you of my simple method of home treatment, send you ten days' free trial, postpaid, and put you in touch with women in Canada who will gladly tell what my method has done for them.

ALFRED STOKES,
General Sec'y.

DOES IT PAY TO KEEP PUREBRED FOWL?

This is the third time my practical experienre has gven an answer to this question.

Why, in the face of all the evidence to the contrary, do so many people persist in thinking that a hen is only a hen, whether thorough-bred, crossberd or mongrel?

The following account of what my small flock of thorough-bred fowl did during 1918 may help to convince some of the people with mistaken ideas, that it pays to keep thoroughbred fowl. You have already published the results secured in 1916 and 1917.

During the first seven months of the year I kept White Plymouth Rocks and Old English Pheasant Fowl. In August I sold the Old English Pheasant Fowls, and since had White Plymouth Rocks only.

The White Plymouth Rocks are a splendid laying strain. May pullets started laying at eaxctly six months old; June pullets a few days over six months; July pullets at six months. They develop well and grow large. Cockerels at six months weighed eight and nine pounds.

The White Plymouth Rocks averaged for the whole flock 144 eggs each, and during the hatching season a nubmer of hens were hatching and brooding chicks for as much as eight or ten weeks at a time.

My fowl are not forced for laying. During the winter months I see them off the roosts on Saturdays and Sundays only, and they are given food only once a day.

Canada's Opportunity On the Highway of Success—What has that to do with GATES? Everything!
PEERLESS LONG SPAN GATES
The gate pictured below is a companion to the Peerless Perfection farm fencing, strong, durable with heavy tubular braces, which stiffens it like a steel bridge. It can be used as an oak door hung by a master mechanic. Lateral and upright wires are securely clasped at all intersections and stretched upon a strong rigid frame of tube or steel electrically welded into one solid piece.
For Looks, Wear and Service
guardian here." For durability its of heavy open hearth steel wire, galvanized and can't rust at any point. For service it is put together to last a lifetime and is the cheapest best gate made. Write Today for Literature describing all our many styles of Gates, also Rods of Farm and Poultry Fencing for farms, parks, residence, park, etc. It will pay you well to get acquainted with Peerless Perfection standard of construction. Write nearest office today. Do it now.
THE BANWELL-HOXIE WIRE FENCE CO., Limited
Hamilton, Ont
Winnipeg, Man.

Average number of hens and pullets during twelve months, 29.

Average profit per head, $1..17.

All young stock raised were from the hens kept, and only cock birds for breeding purposes were purchased, and, of course, charged for in expenses.

Eggs for hatching were sold in season for $2.00 per setting (15). Hens, pullets and cockerels were sold for breeders, prices ranging from $2.50 to $4 each. You will note that prices secured were reasonable, and really below the real value of the stock. As the birds sold weighed (live) from six to ten pounds each, even if they had been disposed of as dressed poultry at the prevailing market price (40c to 60c per lb.) there would have been nearly as great a profit.

Jan. 1st, 1918, stock, houses feeds, etc., on hand	$209.00
Dec. 31sta, 1918, expenses	218.68
	$427.68
Deec. 31st, 1918, receipts during year	$375.60
Dec. 31st, 1918, stock, etc. on hand	231.00
	$606.60
Balance profit	$178.92

But do not let any person run away with the idea that such results can be secured with any kind of a hen, or through indifferent and careless marketing methods, for they are certain to invite a failure. From my experience and from observation of the methods and results secured by others, I am convinced that success can only be secured by keeping thoroughbred, bred-for-a-purpose fowl, combined with the best busines methods of conducting the business.—W. C. R., New Brunswick.

It is natural for chicks to thrive and develop very rapidly, and if they do not it is because of some unnatural condition. The well hatched healthy

chick does not need doctoring any more than does the healthy well born child. With the baby chick there are many unnatural conditions which commonly hinder its natural development, first and foremost of which isa lack of vigor in the parent stock, and this is sometimes due to breeding from immature pullets hatched late the previous season.

TEN HENS—10,000 EGGS

The common teaching is that pullets are so much more profitable than even year-old hens that it is advisable to change the flock each year. There is one successful egg farm on the Atlantic Coast, however, which goes on the assumption that a Leghorn at least is profitable as long as she lives. We doubt if even this farm could furnish as remarkable examples of productivity as has been furnished by 10 White Leghorn hens owned at the Ohio Experiment Station which have produced 10,000 eggs. Two of the hens are nine years old, six are eight years old, and two are five years old.

The "ace" of the lot, C-34, has 1179 eggs to her credit; she is followed closely by C-38, with a total of 1147. The other eight follow closely in production. Two of the hens are from an original lot of pullets purchased in 1909—when the poultry investigational work was begun at the Ohio station.

None of the hens show any particular effects of old age. While their annual production is less than during the earlier laying periods, they still lay regularly during the spring and summer months. Each of these hens has produced approximately $25 worth of eggs, at ordinary market prices, at a feed cost of about $10.

This is not an argument for keeping old hens in the farm flock. Even in the good pure bred flock the pullets will be the most profitable and only by the most rigid culling and selection will it be good business to carry more two-year-olds than are necessary for the breeding flock. The Ohio results do hold out a hope, however, of a possibiilty through breeding and selection of developing a strain of fowl that will be profitable over a series of years.

HOME GROWN FEEDS FOR YOUNG CHICKS

There are numerous combinations of feeds that will make satisfactory rations for chicks. However the feeds that are available or that can be readily secured, may determine to a large extent the make-up of the ration.

Keeping that in mind the Ohio Experiment Station recently conducted an experiment to find out the advisability of feeding home-grown grains to chicks, and the results have been highly successful. The chicks used were single comb White Leghorns, hatched in an incubator, and kept in a brooder house 10 by 12 feet, which was heated by a colony brooder stove. The feed consisted of cracked corn of good quality and a mash mixture of two parts by weight of ground corn, three parts bran and one part fine meat scrap together with a few boiled eggs at the beginning and water and grit. They were fed five times a day for the first three weeks, after which the mash was placed in hoppers and the chicks allowed free access to it. At the beginning of the test there were 239 chicks, and six weeks later there were 227, which goes to prove that a satisfactory feed can be made up at home. The mortality was light and the chicks are reported to be doing remarkably well. This ration will serve as a general guide in making up the feed for chicks, but it should not be assumed that this is the only ration that will give good results.

Candy a Splendid Food

One of the most attractive forms in which food can be eaten—is candy.

Candy is composed principally of sugar, nuts, fruits, some fats such as butter, and chocolate.

All these ingredients are recognized by eminent medical authorities as food products, which the system craves and demands.

Let us examine their food values separately.

We all know that sugar is a body-building essential; about one-quarter pound of sugar being required by an adult every twenty-four hours.

Nuts and fruits yield a high percentage of nutritious materials.

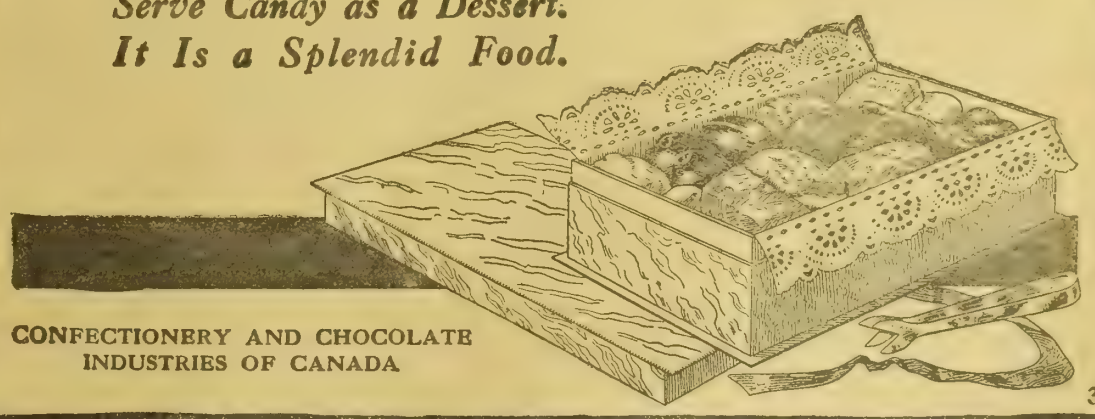
Fats supply the bodily fuel and should be used in every dietary.

Chocolate is a delightful stimulant, especially valuable in restoring energy.

Combine these ingredients and are they not still food?—satisfying, nutritious, essential and in a most delightful and properly balanced form.

Eat more candy. Candy is beneficial to all and harmful to none.

Serve Candy as a Dessert.
It Is a Splendid Food.



CONFECTIONERY AND CHOCOLATE INDUSTRIES OF CANADA

And a slugglish patience-tryer;
If there's aught you would acquire,
Do it now.

WHEN JOHNSON WAS MADE TO SEE

The new horse proved more unmanageable than anticipated, and when Johnson returned it was in no pleasant frame ot mind. As he left the country road and turned into his own lane he passed a field where some of the men were at work. One of them called to him inquiringly: "Ain't it 'bout time for the dinner bell to ring?"

"Why, yes, of course. Ain't it rung yet?" He looked at his watch. "Ten minutes of 1," he called to the men. "Drop your tools an' come to the house." Then to himself: "I'll soon have an understandin' 'bout this thing. Farm hands can't let their work wait on wimmen's laziness. Git on there, Dan." He did not go on to the barn with the horse, but stopped at the kitchen door and strode in furiously. "What's all this meana—"

Then the unnatural stillness made him pause and glance around. There was no fire in the stove, no signs of food being cooked and in the sink were the unwiped dishes of the morning. What did it mean? An unreasoning terror of the silence began to possess him. In his long remembrance of the room he had known nothing like this. It had always been a scene of busy cheerfulness and order during his married life, and durng the days of his boyhood, when his mother had presided over the kitchen. He caught sight of a letter addressed to himself and he opened it eagerly.

"Dear Husband," the letter began, "I am going away for a week or so to give Mary a rest. The poor child is worn out and a little trip will do her good."

"Huh!" he grunted ,breaking off suddenly. "Little trip, indeed. Seems like she's a millionaire, sure enough. Gone to that sister Mary of hers, of coure. Well, I'll send Jake after her with the lumber wagon," grinning spitefully; "that'l jounce some sense into her."

Then he read on: "You might get Jake or Bod to help you some with the cookin'. But, of course, it won't be much work, as you often tell me, so mebbe you can do it all youreslf, at odd times, when you ain't busy. Only don't forget the settin' hens an' the cheese curd, an' the cowcumbers to pickle, an' to scald the milk pans when you wash 'em, an' to gather up thte eggs every day, so they'll be fresh; an' remember the cat craves her milk an' that the dog must be kept shut up or he will kill the young chickens; an' please don't forget to use hot water in washin' dishes like you did when I had that bad spell, an' Mary was down with measles, an' you had better use the self-risin' in making bread as the yest might bother you. An' that reminds me, don't forget to clean out the stove twice a week; if you don't it'll stuff up an' smoke. An' then there's——" "What fool rigmarole's she tryin' to git off, any how?" he snorted wrathfully. "Don't she suppose I know as much about what's to be done as she does? An' I won't send for her neither. not by a long shot. That's just what she's fishin' for. Seems to think the world can't move 'cept she's turning the crank. Huh! they can stay till doomsday for all I care!" He shook the letter in an imaginary face, and laughed maliciously. "That's jest the very thing. Keep quiet, like I don' scasely know they've gone away, an' theen 'bout tomorrow night they'll soce sneakin' in like hungry chickens fors omething to eat. She an' that sister Mary of her's can't git along together no how.'"

"Hey!" Nothin' to eat inside there yet?" and burly Jake backed by the other five hands, lumbered wonderingly into the kitchen. "No fire in the stove! Wher's the wimmen folks? What's up?"

Johnson started, then drew himself together huriedly. "Just run up to Mary Brown's for a day or two," he answered gruffly. "The visit was—er—pretty sudden, an' they had no time to git dinner. But I guess we can patch up one among us, eh Jake?" —trying to pass it off lightly. "Git jest as good dinner's the wimmen folks, an' a might sight quicker."

"Course we can," cried Jake, with alacrity, and pleased at the thought of so novel a task, "an' one we'll like better, too. Men folks know jest what men folks want. We'll have inyuns an' tatters, an' coflee that's strong enough to taste."

"An' biled cabbage," reminded one of the men earnestly.

"An' tripe," "An' baked beans," "An' greeen corn," chimed in the others, moistening their lips in anticipation of favorite dishes.

"Come, come, we can't have everything at once," expostulated Johnson ompatiently. "Here, pitch in, all of you, an' help what you can. The field's got to be hoed 'fore dark."

But in spite of the superabundance of assistance the dinner progressed slowly and it was 2 o'clock before the men drew their chairs to the table, red faced and fuming at the stupidity of each other. And in spite of the fact that the dinner was of their own cooking they tasted suspiciously of one dish and another and pushed their plates back, then tried again, grimacing and scowling, and at last rose sullenly and shuffleed from the room.

Johnson glanced at his watch as the last disappeared. He had work of importance to look after, so the dishes and food were left on the table and cooking utensils on the stove and floor, wherever they had been dropped in the hurry. It would be time enough enough to attend to them when he returned.

But long before that the sun had fallen behind the apple ochard and the kitchen was so full of shadows as to call for artificial light. He was tired and cross, and this did not facilitate dish washing and supper getting. When the men came in from their late chores he was bristling with angry impatience, and his face and clothing were spotted with the grease and soot of reckless contact with dish water and cooking uuten sils. Again they were called on for assistance, and again—after some of the unsatisfactory supper was forced down—the dishes and food were left upon the table to await the time when it would be necessary to remove them

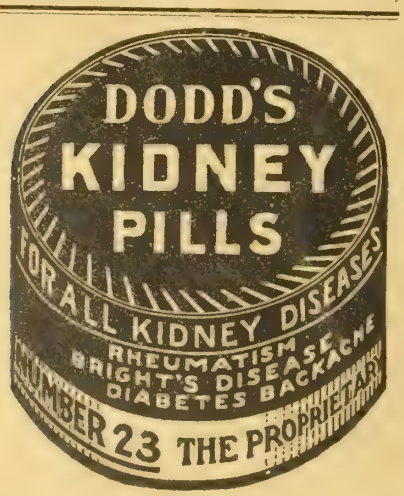
One day longer the "menfolks'" cooking was persisted in, but by that time the pleasant kitchen had been transformed from a place of orderliness to a den of chaotic neglect. No dishes had been washed and many conflicting foods had been cookeed on the same utensil without the separating use of soap and water. Jake was fond of "iniyuns an' taters," but decided he did not care to have them flavored with chocolate, while the lovers of "biled" cabbage were equally firm against their favorite dishes being disguised with the odors of ooking which hd gone before. Moreover, Jake declared that all the bies of the whole county had come to feast with them and that he, for one, was going to take his meals henceforth over at Neighbor Gould's. Bob and another man agreed with Jake, while the other two guessed they could pick up a few days' living in the apple orchard and off the huckleberry and blackberry bushes. But they were agreed with the rest in having no more to do with menfolks' cooking.

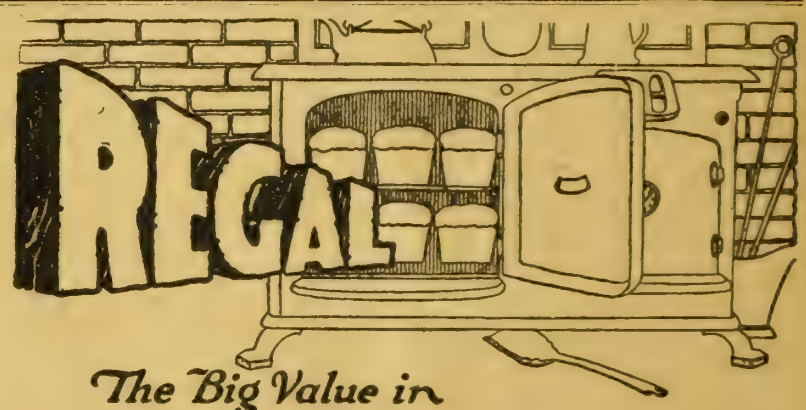
So the next morning Jake was sent unceremoniously to Mary Brown's with orders to bring the womenfolk's home, whether or no.

"Jest tell 'em we're too busy with the hoein' now to bother with cookin'," Johnson snarled. "If 'twas any other time we wouldn't care a continental whether they come or stayed. It's jest their aggravatin' way to pick out a time like this."

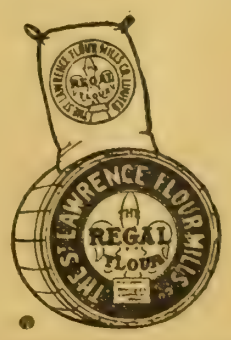
But when Jake retuned with the informotion that Mary Brown had neither seen nor heard of them his anger gave place to wonder and then to dismay. What was he to do? In the end he sent for one of the Gould girls, and after two days sent her back and tried one of the Cady girls. But she was no better. Against his will he compared their work and his wife's. Then he tried it again himself, but with less satisfaction than before. In a week he was so far humbled as to acknowledge to Jake in private that he would rather hoe corn sixteen hours a day than prepare a single meal of victuals.

"Then why don't you git the womenfolks back?" Jake demanded. "We can't stand this much longer. If ye don't do something mighty quick this farm's bound to go to everlastin'





The Big Value in
FLOUR



OF all the products of the oven, there is none so important as a good loaf of bread. This test of "REGAL" has established its reputation as the big value in flour.

Limited
MONTREAL

ruin. That's my say."

Another two days brought Johnson to the limit of his endurance, and then came relief in the shape of a letter from the city, which read:

"Dear Husband: "We've been havin' a pretty good time, but things here do cost awful. I wanted to buy some new dresses an' books for Mary, but can't for we'll have only jest enough to pay for our fare home after stayin' here another week."

"Another week!" groaend Johnson. "How'll we ever get through it?"

Then he continued. "We tried to find that machinee place that humbugged you, but couldn't. It's a fraud, jest as I thought. I hired a lawyer an' he hunted round some an' went to the post office an' got hold of a lot of letters. One of 'em was from you, which you must have sent after we left. It had $1,500 in it. But don't fret. We've got it back all safe."

He drew a quick hard breath and then read the short postcript. "I forgot to say that the lawyer cost me $5. Don't forget the things I wrote you about. We'll be home a week from Saturday. Good bye."

He dropped the letter and leaned his head on his hands. Thinking was something unusual to him, but this time it was to good purpose, for it ended in his writing, in a cramped, laborious hand:

"Dear Wife: I take my pen in hand to answer your welcome letter. We-'ve been havin' an awful time an' want you to come beack jest as soon as you can. All the men will be glad to taste your cookin' again and I won't never say nothin' more about it bein' easy. I'm sorry 'bout Mary's dresses. You better take a hundred out of that fifteen hundred an' buy whatever you want. An' I'm free to say I think it a good ideer to have a hired girl. One of the Gould or Cady girls might do with some one to go ahead. But you jest pick out whoever you want. I don't want anything more to do with the kitchen. Only come home soon."

STAINS

Greease Stain.—Wash in warm water and soap. If dust collected on stain, on cotton or linen, use javelle water; if on wool or delicate fabrics, use ether, alcohol, benzine.

Ink Stain.—Use potassium permanganate and oxalic acid; or salts of lemon, or peroxide or sour or butter milk.

Printer's Ink.—Removed by Hudrochloric Acid and borax added in water. Simpler methods, citric acid and cream of tartar, salts of lemon or lemon juice and salt.

Machine Oil.—Remove by washing in soap and cold water, or rub it with turpentine until it disappears.

Medicine Stains: Soak in alcohol. Alcohol is solvent for most drugs.

Mildew.—When fresh, wash in cold water; if not, use Permanganate and oxalic acid, or javelle water; wash.

Paraffin.—Warm iron and blotting paper; or rub with benzine, having blotting paper underneath.

Perspiration.—Wash in warm water and soap, then bleach in sunshine; or use javelle; or bleach if in cotton or linen; is silk or wool, use sodium hydrosulphate.

Pitch or Resin.—Benzine is best.

Scorch Stain.—Hopeless on silk or wool; but on cotton or linen hang in sunlight or wash in warm water and hang in sunlight.

Spanking Doesn't Cure!

Don't think children can be cured of bed-wetting by spanking them. The trouble is constitutional, the child cannot help it. I will send **FREE** to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatment is highly recommended to adults troubled with urine difficulties by day or night. Write for free trial treatment.

Mrs. M. Summers
BOX 309 WINDSOR, Ontario

"Congratulations, My Daughter, You Are Looking Fine"

"AND why shouldn't I look well after using Dr. Chase's Nerve Food?"

"Is that what has made such a change in your appearance? You were so pale and thin, I was rather anxious about your health."

"Why, I have gained fifteen pounds, and I feel so well, too."

"And you have such a good, healthy color. Your blood must be rich and red."

"I knew you were suspicious of anything that our doctor did not prescribe, so I said nothing about it to you."

"Well, I will not have any doubts about Dr. Chase's Nerve Food in the future after what a healthy looking girl it has made of you."

"Yes, and I feel so differently, too. I was so nervous and irritable that I was very easily annoyed and upset. Then I would have those fearful nervous headaches. But, thank goodness, that is all over, and I know what to give credit to for the change."

"I am very glad you are so well again and think Dr. Chase's Nerve Food a very valuable medicine, since it has done you so much good."

Miss Gertrude M. Burrell, Clementsport, N.S., writes:

"I have used Dr. Chase's Nerve Food with splendid results. For a number of years I was afflicted with nervousness, and six years ago had a complete breakdown. I had no control of my nerves and had terrible hysterical spells. I could not sleep, had night sweats, awful dreams and nightmare. My physician gave me medicine to put me to sleep every night, and another kind to take every two hours during the day, but it did not seem to do me any good only while I was taking it. I never really expected to get well. Reading about Dr. Chase's Nerve Food one day, I gave it a trial, and the results from the first box encouraged me, so I continued its use, and found my nerves getting steady and stronger. My appetite improved and I gained in strength, ambition and flesh. Now I am able to do considerable work, and can highly recommend Dr. Chase's Nerve Food as a good tonic for the whole system."

(Alonzo W. Daniels, J.P., says: "It gives me great satisfaction to vouch for the testimony of this young lady and the benefit she has received from your wonderful discovery.")

Dr. Chase's Nerve Food, 50 cents a box, 6 for $2.75, all dealers, or Edmanson, Bates & Co., Ltd., Toronto. On every box of the genuine you will find the portrait and signature of A. W. Chase, M.D., the famous Receipt Book author.

Shoe Polish.—Black—rub with lard or grease, wash in warm water and soap. Bronze—use HCL. Tan—oxalic acid, wash, ammonia, wash.

Varnish.—Wet stain with turpentine and alcohol; sponge with vinegar to restore color removed by alcohol.

Wax.—Absorbent paper and warm iron.

Wine.—Cover immediately with salt and boiling water or pour boiling milk over it.

Acid.—Ammonia, then sponge with water.

Analine Dye.—Use javelle water, then boiling water, and rinse well.

Blood.—Warm water, or warm water and ammonia and naptha soap, or raw starch, on delicate fabrics.

Blueing.—Boiling water or javelle water.

Brass.—Rub with lard, then wash.

Chocolate.—Borax and cold water.

Coffee.—Boiling water.

Cream.—Cold water, then water and soap.

Fruit.—Boiling water as for coffee. Borax will assist. For cottons and linens, use javelle solution and boiling water in equal quantities. For woolens, silks and colors, borax and ammonia may be used.

Glue.—Warm water will usually dissolve glue; if not, apply vinegar with cloth.

Grass.—Wash fresh stain with cold water; rub with molasses, let stand a few minutes and wash with warm water. Alcohol and ether will dissolve the green coloring matter when material can not be washed.

VOL-PEEK
Mends Pots & Pans
Cooking utensils, Graniteware, Aluminum, Enamelledware, Tin, Copper, Brass, Iron, etc. Easy to use, no tools required, ready for use in 2 minutes. Saves a pot for 2½ a cent. 15 cents at your Dealer, or postpaid by Vol-Peek, B-Co., Box 1034, Montreal

DIARRHOEA
COLIC
AND
CRAMPS.

These and many other bowel complaints such as dysentery, cholera morbus, cholera infantum, or any other looseness of the bowels, may be quickly relieved by a few doses of Dr. Fowler's Extract of Wild Strawberry. It is without a doubt one of the safest and most reliable remedies in existence. It has been a household remedy for the past 74 years.

Its effects are instantaneous, and it does not leave the bowels in a constipated condition

Mr Joseph Dale, 730 10th St., Saskatoon, Sask., writes:—"Having used Dr. Fowler's Extract of Wild Strawberry for many years, I am in a position to strongly recommend it for diarrhoea, colic, and cramps. In violent cases of alkali water poisoning it has proved a remedy of superlative quality, and many a time some poor harvester or laborer has blessed me for the administration of a dose of this valuable and highly efficient remedy. I would advise every homesteader and thresherman to keep a bottle on hand."

If some unscrupulous druggist tries to talk you into taking some other preparation when you ask for "Dr Fowler's" refuse to take it, as these no-name, no-reputation substitutes may be dangerous to your health. The price of the genuine is 35c a bottle, and put up only by The T. Milburn Co., Limited, Toronto, Ont.

BRINE CURING MEATS AND CORNING BEEF

Bine-cured meats are beset for farm use, for the reason that a suitable place for dry curing is not usually obtainable. It is also less trouble to pack the met in a barrel and pour on a brine than to go over it three or four times to rubu in the salt. The brining method also gives better protection from insects and vermin. Trouble is somtiimes experienced in keeping brine, but if pure water is used and directions followed in making the brine there should be no difficulty n keeping it for a reasonable length of time. During warm weather brine should be closely watched. If it becomes "ropy" likie syrup it should be boiled, or new brine made. A cool, moist cellar is the best place for brine curing. Dry curing may be done successfully in a cellar also, though even more moisture is needed to effect a thorough cure. The cellar should be dark and tight enough to prevent flies and vermin from damaging the meat.

Corned Beef

The pieces commonly used for cornnig are the plate, rump, cross ribs, and brisket, or in other words, the cheaper cuts of meat. The loin, ribs, and other fancy cuts are more often used fresh, and, since there is more or less waste of nutrients in corning, this is well. The pieces for corning should be cut into convenient-sized joints, say five or six inches square. It should be the aim to cut them all about the same thickness, so that they will make a neven layer in the barrel.

Meat from fat animals makes choicer corned beeef than that from poor animals. When the meat is thoroughly cooled, it should be corned as soon as possibe, as any decay in the meat is likely to spoil the brine during the corning process. Under no circumstances should the meat be brined while it is frozen. Weigh out the meat and allow eight pounds of salt to each 100 lbs.; sprinkle a layer of salt one-quarter of an inch in depth over the bottom of the barrel; pack in as closely as possble the cuts of the meat, making a layer five or six inches in thickness; then put on a layer of salt, following that with another layer of meat; repeat until the meat and salt have all been packed in the barrel, care being used to reserve salt enough for a good layer over the top.. After the pacakge has stood over night, add, for every 100 pounds of meat, four pounds of sugar, two ounces of baking soda, and four ounces of saltpeter dissolved in a gallon of tepid water. Three gallons more of water should be sufficient to cover this quantity. In case more or less than 100 pounds of meat is to be corned, make the brine in the proportion given. A loose board cover, weighted down with a heavy stone or piece of iron should be put on the meat to keep all of it under the brine. In case any should project, rust would start and the brine would be spoilt in a short time.

It is not necessary to boil the brine except in warm weather. If the meat has been corned during the winter and must be kept into the summer season, it would be well to watch the brine closely during the spring, as it is more likely to spoil at that time than any other season. If the brine appears to be ropy or does not drip freely from the finger immersed and lifted, it should be turned off and new brine added, after carefully washing the meat. The sugar or mollasses in the brine has a tendency to ferment, and, unless kept in a cool place, there is sometimes trouble from this source. The meat should be kept in brine 28 to 40 days to secure thorough corning.

HANDICAPPED CHILDREN

Children who stammer, children who squint, children who have any other remediable defect, are chilrden whose parents should at once act to correct that defect. Otherwise they will be allowing their children to grow to manhood and womanhood cruelly and needlessly handicapped for life's battles.

What such defects may involve is strikingly indicated by the pathetic lament of an adult stammerer:

"I realize that I am abnormally sensitive, diffident, self-conscious, taciturn, and seclusive. But how could I help being thus?

"People have treated me as an inferior from childhood, when I first began to stammer. They have continually wounded me, they have forced me to be self-conscious, they have made me taciturn and seclusive.

"My school days were an agony because of the way playmates teased and mocked me. Even the teacher found it hard to be patient with me. I realized this, and it did not improve the state of my mind.

"If I avoid people, is it to be wondered ? At best it is hard for me to talk, and odubly hard when people stare at me and snap at me, as they often do when I am obliged to ask questions.

"No doubt I should show more courcourage. No doubt I should control my feelings better than I do. I admit all this. But is it possible when all the while I am made to feel that I am looked upon as a strange, exceptional being?

"Do not blame me for my shorcomings. Blame society, which has forced me to take refuge within myself."

The blame, in fact, should go back to the parents who thoughtlessly permit the continuance of conditions which might be remedied if taken in hand soon enough.

Themselves quite free from speech, eye, or other defect, and perhaps of a stolid temperament, they do not sufficiently appreciate the mental suffering which by their negligence they are imposing on their children.

Or it may be that they take it for granted that nothing can be done to correct the defect they deplore.

"The poor child will have to put up with it ," they say to themselves. "It is something that cannot be helped."

If the defect really is irremediable, their attitude is the same one. And they cannot be too zealous in training their unfortunate child to bear its burden patiently. But first they should make absolutely sure it is a burden which must be borne.

Modern medical science can do some wonderful things, even as regards seemingly hopeless defects. For the sake of the child's later happiness and success it should, therefore, be promptly given the benefit of a careful medical examination.—By H. Addington Bruce.

IS YOUR HEART WEAK?

TEST IT OUT.

The way to find out if your heart is weak is to put your finger on your pulse.

The average heart of the average man or woman should beat 70 times to the minute. If it beats much below or above this average there is something wrong. There may be palpitation, shooting pains through the heart, sleeplessness, shortness of breath, faint and dizzy spells, waking up in the night as if smothering, a feeling of oppression, the feet and hands become clammy and cold, a bluish tinge appears about the lips, the blood rushes to the head, or there is a sensation of "pins and needles". If any of these symptoms arise take Milburn's Heart and Nerve Pills, and you will find they will fix up the weak heart in no time. They do this by regulating the heart's action and invigorating the nerves.

Milburn's Heart and Nerve Pills are 50c. a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

DAILY CARE OF HAIR

The hair needs a certain amount of brushing—not the hundred strokes once considered vitally necessary, but only enough to smooth out the looser snarls and to induce a fresh supply of oil into the hair. The best sort of brush is one of stiff bristles mounted on a rubber cushion — there are several makes like this—for the cushion gives as the bristles are pulled through the hair, and the pressure on the scalp is never harsh in one spot. Such brushes are easily kept clean, too.

Following a few brisk strokes with the brush, the hair can be combed and arranged for the day. At night, it should be shaken down, three times a week a tonic should be massaged into it, every night the scalp should be massaged with the fingers. This is done by moving the scalp in small circles over the skull, to loosen the skin and allow a greater flow of blood to the roots. Then hanks of hair should be prasped in the hand and pulled from the head—literally pulled until the scalp is drawn a little way from the bone. This weeds out the weak hairs, for new strong ones to grow in from their roots, and it brings the blood into the scalp. The hair is brushed then, ending with a few strokes of the brush with a piece of absorbent cotton over the bristles. The idea here is to wipe off the dust from the hairs themselves and to give it the much desired gloss. I have found using the absorbent cotton so as effective as using a bottled hair polish.

DON'T LET YOURSELF GO TO SEED

The days when the woman of forty was considered passe are the days of long ago. The woman of forty in the summer of 1919 can look like a woman of thirty if she wants to. She need not go to a beauty specialist to accomplish this camouflage if she will spend a little time on herself every day, using the many little home helps that are within the purse possibilities of every woman.

So many women ask, "Is powder harmful o the skin?" Most assuredly it is not harmful if you get a standard make and know how to use it properly. Surely it is better to see a woman with soft, velvety skin rather than one whose face is shining in the summer sun. But before applying powder, rub a good cold cream into the skin. A good cold cream means one made without animal fat, an ingredient which induces a growth of hair on the face. Select a cold cream made from vegetable oils. Ask your druggist for a cream WITHOUT lanolin in it. That is sheep,s fat, found in many of the poorer grades. Having rubbed the cream into the pores of the face. wipe off well with a soft, old towel, then dust the face with powder, using a shade that suits your complexion. Face-powders come in four shades, white pink, Rachel, and natural. At night, before retiring, wash the face with warm water and a pure soap, thus opening the pores and givink the skin a chance to "breathe."

A Cure for Sunburn

As a cure for sunburn the use of powder is also invaluable. If you have acquired a coat of burn that is going to smart, do not wash with water, no matter how dirty the face may be. First wash with witch-hazel to get the dirt off. Then apply a coat of vanshing cream and finally dust with a good talcum powder. If you do this, you will have no bad effects from the longest and hardest automobile rides you've ever taken. If you give your face this little bit of care when you come from bathing in salt water, your skin will be soft and smooth. But if you let the salt water dry on the face and then go into the sun, your pores will become coarse, and your skin will bt rough.

Many women prefer a bottled lotion which is healing in cases of sunburn. This to must contain non-hair growing oils.

Here isa little secret I learned from a French beauty specialist who made a big charge for a simple remedy any woman can appy at home. So many women have a little dark fuzz on the upper lip, and if you keep pulling out these hairs they only come back— oftne times at the rate of two to one.

There is but one way to get rid of these hairs permanently, and that is by the electric needle, which should only be handled by experts . But it is possible to bleach them out so that they will barely show.

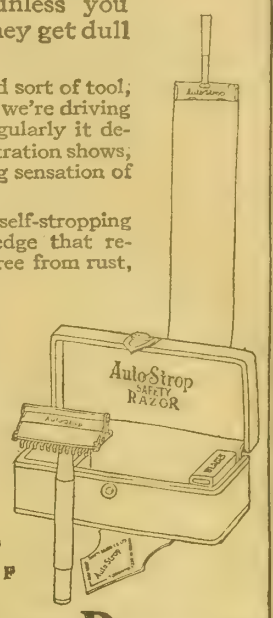
Mix an equal quantity of ordinary household ammonia and peroxide in a small bottle. Now take a piece of absorbent cotton in a pair of tweezers, dip in thic mixture, and apply to the upper lip, meanwhile holding the nose with the other hand, so that the fumes will not bother you. It will evaporate in a moment and you can breathe comfortably through your mouth. Repeat this application every night and morning for a week and you will be delighted with the result. When the lips get dark again repeat the treatment—it is perfectly harmless.—By Alice Lane.

Do you shave with a saw?

THAT question may sound funny, but you know how it is with tools; unless you hone or sharpen them regularly they get dull and lose their cutting edge.

After all, a razor is a tool. A very refined sort of tool; it is true, but still a tool. And the point we're driving at is unless a razor blade is stropped regularly it develops an edge very like a saw, as the illustration shows, and causes that pulling and after-smarting sensation of which you complain.

Not so with the AutoStrop Razor. For the self-stropping feature, you see, reforms the saw-like edge that results from shaving, it keeps the blade free from rust, and it provides you with a keen-edged blade for every shave. The beauty of it is you don't have to remove the blade from the holder to sharpen it, nor do you have to take the AutoStrop Razor apart to clean it. From first to last—stropping, shaving and cleaning—the blade remains in the razor.



Razor, strop and 12 blades complete, with money-back guarantee, $5.

Editor Motor Service Bureau Review of Reviews...

UNDILUTED CHARGES FOR THE ENGINE

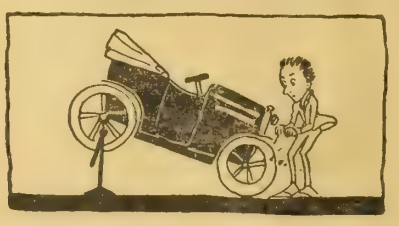
If Your Engine Misses When Idling, Look For Air Leaks

When the piston of an engine starts downward on the intake stroke, it creates a partial vacuum in the cylinder space above it and the full atmospheric pressure, acting at the carburetor air intake, pushes carburetted air through the carburetor, intake piping and inlet valve into the cylinder. This is the way the cylinder gets its charges. The supposition is that nothing enters the cylinder except by this path—air through the carburetor air intake and vaporized gasoline through its fuel nozzle. If gas enters the cylinder in any other way, carburation is interferred with, with a tendency toward a diluted or polluted mixture and perfect engine operation is prevented. The following are some of the points through which stray air or exhaust gas may accidentally enter the cylinder if anything is wrong: A badly seated carburetor auxiliary air valve; a throttle valve stem worn in its bearing; an imperfect gasket between the carburetor and intake pipe; a leaky manifold branch connection to the intake port; a defect in a manifold casting; an intake valve stem which has worn loose in its guide, leaving a free passage from outside air between these parts; a leaky cylinder head gasket; a bad gasket under a valve chamber cap; a spark-plug leaky around its shell or at its core packing; a badly seated valve cage or a priming cock with leaky valve or threads. At all such points the outside air is always ready to crowd in, when there is a partial vacuum in the cylinder. Exhause gas from the crank case may enter to pollute the incoming charge past ill fitting piston rings and undersize pistons or from the exhaust piping past a badly seatng exhaust valve. At full throttle, the cylinder vacuum is slight and the leak areas are small compared with the intake pipe area, thus minimizing the stray air that enters, but at nearly closed throttle the cylnder vacuum is high and the amount of air entering through leaks may become large as compared with the volume of charge, diluting the latter until its combustibility becomes uncertain. In fact, the most common cause of irregular operation, at idle or very low spreads, is air leaks, and engines that have been long neglected are very likely to operate "raggedly" on this account.

TO TELL WHEN VALVES ARE CLOSED

A. M .A. asks: (1) How can I tell when both valves of a cylinder are closed so that, when I put in carbon remover, it will not run out? (2) Why is it that, in cold weather, I can hardly crank over my Ford engine unless I jack up the rear wheels?

Answer: (1) When a valve is closed, it can usually be rotated rather easily by turning its stem with the



fingers. If both valves of a cylinder can thus be turned, they are both of them free from their push rods and thus in their closed position. Another method of determining this is as follows: Remove the tmer cover and note which contact the roller is on. The cylinder that is sparker from this timer contact has its valves closed. (2. Your clutch is dragging and, when you crank the engine, the whole car would move if the brakes were not acting. When you jack up the wheels, the engine and transmission can be turned over wtihout moving the car. This dragging may be due to faulty high-speed clutch adjustment, which can be corrected by changing the setting of the clutch lever screw, or it may eb caused by the use of oil, which becomes too sticky when cold, so that the clutch plates cling to each other, even when in the released position.

VOLTAGE OF FORD MAGNETO

W. A. B. asks: How many volts does a Ford magneto develop and is an alternating current voltmeter the instrument to measure it with?

Answer: The voltage generated increases with the engine speed and, according to a recently published curve,

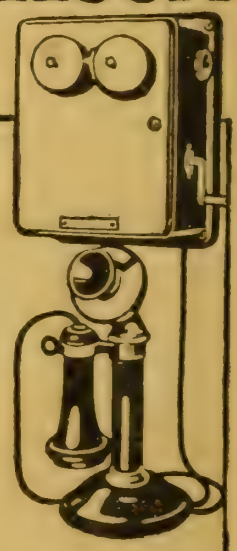
Stromberg-Carlson Telephones



Make the Service Better on Farm and Village Lines

Enable you to talk and hear easily no matter what the distance. Are equipped with the big five bar generators that are bound to ring every bell on the line every time.

Both Desk and Wall Telephones have the same standard equipment and are equally strong and durable.

We illustrate the simple, convenient desk telephone which can be moved about the room and so is always at your elbow ready to answer.

Equipped with high efficiency transmitters and receivers, self-cleaning lightning arresters and many new refinements which make Stromberg's give such satisfactory service.

SEND FOR FREE BOOK No. 95

It describes all Stromberg Apparatus. Explains how to install and take care of your telephones. Tells how to organize and equip a party line among your neighbors and explains just why the experience gained in building over 2,500-000 Stromberg Telephones guarantees the kind of service you need.

Send for this Free Book and put your problems up to our engineers—they will plan your system and furnish estimates without cost.

Stocks carried at Toronto, Regina and Seattle.

Stromberg Carlson Telephone Mfg. Co.

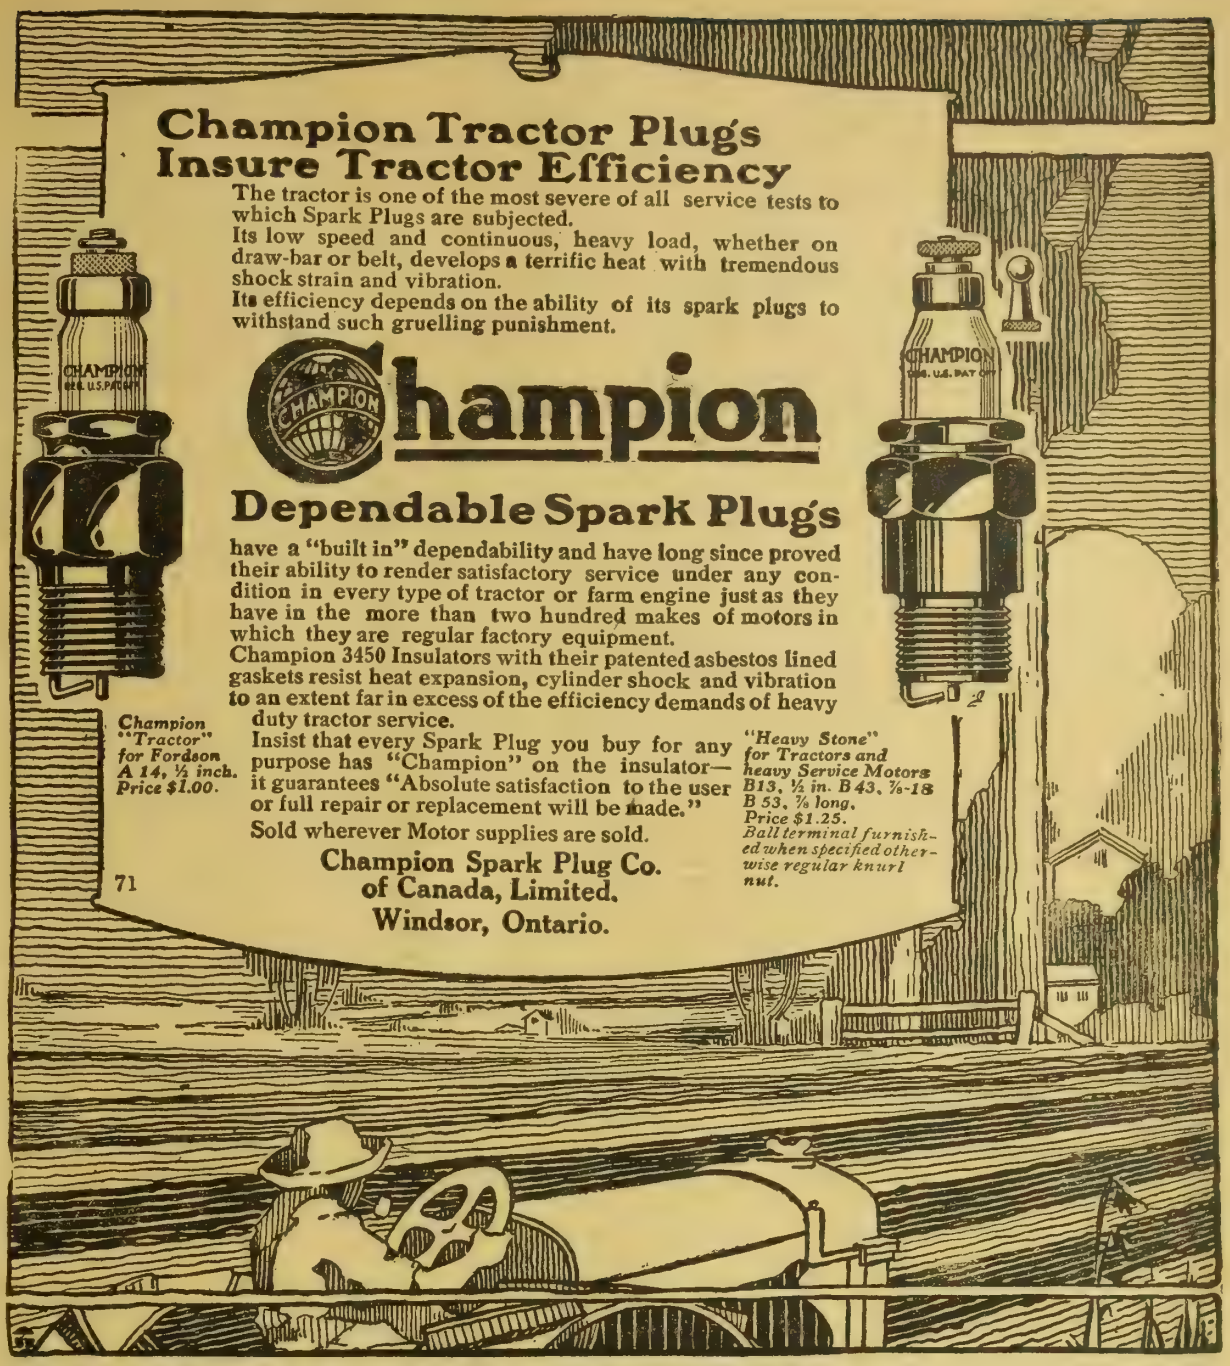
10 FRONT ST. EAST TORONTO, CANADA

it is about 15 at 500 r. p. m., 24 at 1000 r. p. m., and 30 at 1500 r. p. m. These figures probably refer to the votlage when the magneto is furnishing ignition current only, or at least when not heavily loaded, as with the headlights. The headlights are fitted with 8-9 volt bulbs and are wired in series, so it is evidently expected that the effective voltage will be 16-18 at the ordinary engine speed. With increasing loads the effective voltage is considerably less than the total voltage generated, on account of the higher resistance caused by the increased frequency of alternation, as speed increases. An alternating current voltmeter containing no iron, would be the best instrument. Many commercial voltmeters contain iron and are fitted for giving accurate results only when used within a narrower range of frequency than that at which this magneto operates.

UNINTENTIONAL "AUXILIARY AIR" .—AIR LEAKS LEAD TO WASTE OF FUEL

So long as an engine is not taken

apart, the air leaks which develop are mainly those resulting from wear of parts, of which the most common and most likely to escape early notice is the wearing of the inlet valve stems in their guides. So much air often comes to enter in this way as to cause an engine to miss on certain cylinders or even to stall, if slowed down very low. Reaming out the guides and putting in new valves with oversize stems, that fit properly, is the usual remedy. If the throttle stem wears very loose, replacement of certain carburetor parts or a new carburetor will restore normal conditions at this point. When the pistons become very leaky or the exhaust valves loose their tightness, the remedy is the same as that for poor compression at these points. There is not much likelihood of a leak developing in the intake system or parts connected with the cylinder head, unless an engine is disassembled and puut together carelessly. Occasionally, a manifold branch connection or the carburetor flange connection may jar loose, but this very rare. After an overhauling, however, almost any kind of an air leak, even to one sufficient to prevent the engine's being started may be discovered, these usually being due to faulty gaskets or otherwise imperfect joits at such points as the carburetor flange connection, manifold branches, valve chamber caps and cylinder head. In case an air leak is suspected, if a little gasoline is squirted about the supposed point of entrance, with the engine running, the fluid will usually disappear very rapidly and skips from too lean a mixture will temporarily cease. As above stated, air leaks are especially bothersome when an engine is fully throttled down. Their effect can be overcome by increasing the amount of gasoline delivered by the carburetor, but when this is done, the result is to make a mixture wastefully rich at larger throttle openings, at least with very many types of carburetor. This is perhaps the worst result of air leaks and the low fuel economy of many old or neglected engines is attributable to this cause, the temptation to secure regular low speed operation by feeding excess gasoline, being too strong to be resisted. While the effect of one small air leak may not be sufficient materially to affect engine operation, the combined effect of many is serious and the way to avoid this is to stop all such leaks as soon as they are discovered, or the flexibility of the engine, at the lower end of its speed range, will be greatly reduced.



Champion Tractor Plugs Insure Tractor Efficiency
The tractor is one of the most severe of all service tests to which Spark Plugs are subjected.
Its low speed and continuous, heavy load, whether on draw-bar or belt, develops a terrific heat with tremendous shock strain and vibration.
Its efficiency depends on the ability of its spark plugs to withstand such gruelling punishment.
CHAMPION
Champion
Dependable Spark Plugs
have a "built in" dependability and have long since proved their ability to render satisfactory service under any condition in every type of tractor or farm engine just as they have in the more than two hundred makes of motors in which they are regular factory equipment.
Champion 3450 Insulators with their patented asbestos lined gaskets resist heat expansion, cylinder shock and vibration to an extent far in excess of the efficiency demands of heavy duty tractor service.
Insist that every Spark Plug you buy for any purpose has "Champion" on the insulator—it guarantees "Absolute satisfaction to the user or full repair or replacement will be made."
Sold wherever Motor supplies are sold.
Champion Spark Plug Co. of Canada, Limited. Windsor, Ontario.
Champion "Tractor" for Fordson A 14, ½ inch. Price $1.00.
"Heavy Stone" for Tractors and heavy Service Motors B13, ½ in. B 43, ⅞-18 B 53, ⅞ long. Price $1.25. Ball terminal furnished when specified otherwise regular knurl nut.

CLUTCH INQUIRIES

T. G. W. writes: The clutch of my ————car makes a ringing sound, when it is thrown out. Why is this and can it be prevented? Also, when it is disengaged, as in going down hill, and the car hits a "bump," I sometimes hear a sound as if some heavy part were loose in the clutch and striking something. What causes this?

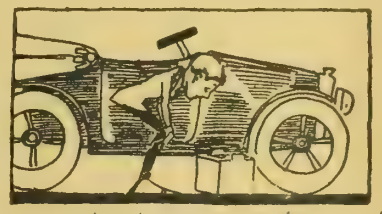
Answer: This clutch consists of two sets of saw steel discs with cork inserts. Saw steel is a very resonant metal, but as long as the discs are pressed together in engagement, they

are prevented from vibrating. When, however, the discs are slightly separated by disengagement, plates of one set occasionally "tick" against or lightly touch plates of the other set and, being free to vibrate, give out the characteristic ring of the metal. We doubt if this can be prevented. It is not good practice to coast with the clutch disengaged. It is not clear how the blow-like sound you hear can be produced by the clutch. It may be due to looseness in the torque member connection to the axle housing, the noise being transmitted forward along the drive shaft, so that it seems to come from the cluutch. Play at the torque rod end makes little ncise, when power is being applied, but often is pronounced when the clutch is out and the torque system is slack.

HYDROMETER MAY BE INACCURATE

W. T. writes: My battery cranks the engine finely and keeps the lights burning at full brilliancy, but no matter how much I charge it, I cannot make the solution in the cells test more than 1,270, while the instruction book says that it should test 1,280 at least. What does this indicate?

Answer: It may be that your hydrometer reads lower than it should and we suggest that you borrow one of proved accuracy and check up yours by it. Even if you find that your hydrometer is correct, there is



no occasion to worry, so long as the several cells of your battery test about alike and you continue to obtain good results. Most likely your battery has lost some acid by "spraying" or was set up with electrolyte that was slightly weaker than normal. If, when charging at the final (minimum rate), each of your cells shows 2.5 volts you can safely increase the acid in the electrolyte so as to make it test 1285 or 1280.

PILES Do not suffer another day with Itching, Bleeding, or Protruding Piles. No surgical operation required. Dr. Chase's Ointment will relieve you at once and as certainly cure you. 60c. a box; all dealers, or Edmanson, Bates & Co., Limited, Toronto. Eggs, 40c per dozen.

THE PROVISION MARKET

Montreal, June 23.—A more settled feeling prevailed in the live hog situation today owing to the fact that the labor strike at the packing houses here has been practically settled, but on account of the above the offerings of hogs today were smaller than usual, and this, coupled with the stronger undertone to the Toronto market on Tuesday, tended to keep prices very firm. The demand from packers for what stock was available was good and a fairly active trade was done in selected lots at $22.50 to $22.75 per 100 lbs. weighed off cars. A steady trade continues to be done in dressed hogs and as supplies were none too large to meet the requirements, the tone of the market is stronger, with sales of city abattoir fresh-killed stock in a jobbing way at $30 to $30.50 and in some instances as high as $31 was realized per 100 lbs. In the Toronto market yesterday live hogs were quoted at $22.50 to $23 per 100 lbs. weighed off cars and at $22.25 to $22.75 fed and watered.

Owing to the extreme heat prevailing of late, the consumption of all lines of smoked meats has steadily increased and this, coupled with the fact that supplies on spot have been none to large to meet the requirements on account of the smaller production, due to the trouble at the packing houses, a firmer feeling has prevailed in the market, but there is no actual change in prices to note as yet. The demand for domestic consumption is good and an active trade is reported in a jobbing way, with sales of 8 to 10 lb. hams at 41c to 42c per lb., 12 to 15 lbs. at 39c and 40c and heavier weights at 37c to 38c, while breakfast bacon sold at 44c to 45c, Windsor selected bacon at 47c to 48c and Windsor boneless bacon at 49c to 50c. A firm feeling prevails in the market for barreled pork, but the demand is quiet, with Canadian shortcut in a jobbing way quoted at $58 to $60 per barrel.

There were no further developments in the market for lard, prices being firmly maintained with a good steady demand for supplies for local and country account and an active trade was done in a jobbing way in Canadian pure leaf grades at 38c to 38½c per lb. in 20-lb. wood pails and at 39c to 39½c per lb. in 1-lb. blocks.

The receipts of provisions today were 1,040 packages lard, 2,699 boxes hams and bacon and 4,571 packages tinned meats.

THE BALED HAY MARKET

Montreal, June 23—There were no new developments in the condition of the market for baled hay today, prices being still maintained uunder a good steady demand for all supplies coming forward, and sales of car lots of good No. 2 timothy hay were made at $40 to $41, No. 2 timothy hay at $38 to $39, and No. 3 timothy hay at $35 to $36 per ton, ex-track.

THE CATTLE MARKET

Montreal, June 23—At the Canadian Pacific Live Stock Market today the offerings amounted to 100 cattle, 375 sheep and lambs, 625 hogs and 1,300 calves. One of the features of the trade at this market was the demand for calves for shipment to the United States, and seven carloads were shipped, and a dealer remarked that if it had not been for this demand prices would have slumped, as supplies coming forward were far in excess of the local requirements. The top price realized today for choice lots of calves was $12 per 100 lbs. and the lower grades sold from that down to $8. Another feature of this market was the demand for selected hogs for shipment to Toronto and seven carloads were forwarded, and the dealer stated that none of them cost more than $21 per 100 lbs. weighed off cars here, while at the Montrea Stock Yards, West End Market, today, sales of selected lots were made freely at $22.50 and in some instances as high as $22.75 was realized. The labor troubles at the packing houses being practically settled, there was ample demand to absorb all the cattle offered and the best steers and heifers offered sold at from $11 to $13 per 100 lbs. cows at from $9 to $11 and bulls at from $8.50 to $10.50, while a few grass fed cattle in poor condition sold at prices ranging from $4 to $8. The quality of the sheep offered was also poor and in consequence low prices had to be accepted for them at from $8 to $10 per 100 lbs., and spring lambs sold at $16 per 100 lbs.

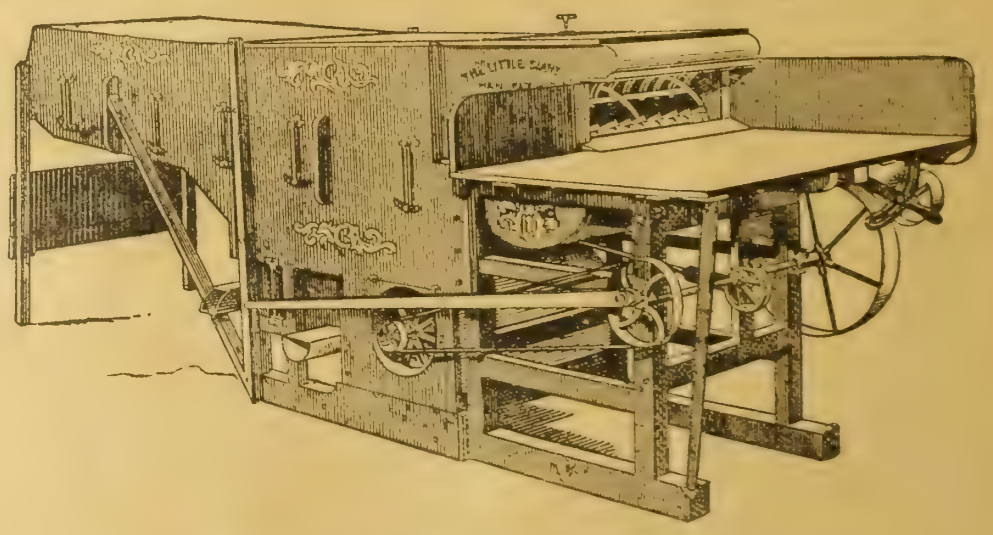
THE LOCAL GRAIN MARKET

The option grain markets today were strong under good buying for both short and long account and prices for corn in Chicago scored an advance of 3c to 4c per bushel, barley 2½c to 3c, rye 1¾c to 2, and oats 1½c to 1¾c, while in Winnipeg oats sold 1⅜c to 1½c higher, and barley 1⅝c. In sympathy with the above the tone of the local grain market today was strong, but there were few changes in prices to note. There was some demand from exporters for barley and sales of car lots of extra No. 3 Ontario were made at $1.45 per bushel, extrack, and one or two round lots of sample barley changed hands at $1.35, ex-store, while car lots of the former to arrive for shipment to the country were quoted at $1.49½ and No. 3 Ontario at $1.48. The trade in oats for local and outside account was rather quiet, the demand being somewhat limited, and only sales of odd cars of extra No. 1 feed were made at 91c, and No. 2 feed at 89c per bushel- extore, while to arrive by water extra No. 1 feed were quoted at 90c, No. 1 feed at 88c, and No. 2 feed at 83c, and Ontario No. 2 white to arrive by rail at 91½c. The demand from over the cable for barley today was quieter and the volume of business small. Sales of No. 2 yellow corn were made in the Chicago market today at $1.72 per bushel, while figure shows an advance of 3c per bushel.

Announcement

Having purchased the Farm Machinery plant from the Sussex Mfg. Co., Ltd., we are now manufacturing the complete line of Farm Machinery previously made by them, including SUSSEX LITTLE GIANT THRESHERS, Wood Cutters, Feed Cookers, Root Pulpers, etc.

We respectfully solicit your orders and enquiries.



Sussex Little Giant Threshers
"The Proven Best"

Wallace Machine Works, Limited, Sussex, N. B.

DR. GRISDALE'S APPOINTMENT

In the appointment of Dr. J. H. Grisdale as Deputy Minister of Agriculture for Canada, Hon. A. T. Crerar has acquiesced to the desire so often expressed at meetings of agriculturists, that a man with a thorough knowledge of agriculture should be at the head of this important department. And for the position no better man could have been chosen by the Minister, for Dr. Grisdale brings to his new office a wealth of practical experience possessed by few other men in Canada. Moreover, the farmers from coast to coast have absolute confidence in his ability, which will undoubtedly result in helping to place the Department of Agriculture on a higher plane in the general estimation of the public.

Dr. Grisdale's promotion to the highest position in the servce, serves to remind those who have followed his career, that his march up through the ranks has been most marked. First farm boy, then school teacher, on to the Ontario Agricultural College, where he graduated with honors, next appointed Professor of Animal Husbandry under the Experimental Farms' system, and finally its director upon the resignation of the late Dr. Sanders eight years ago. This connection with the Experimental Farms' system for nearly twenty years brought him into close touch with prominent live stock men and farmers in all provinces of the Dominion, which gave him a splendid opportunity to study all phases of the work, and the needs of the industry. The observations gleaned will serve him well now in developing a policy, that will lift agriculture, the most important of all our industries, on to a higher level than it has heretofore occupied, promote harmony in all branches of the service, and eliminate that nasty, restless spirit of discord, that has had a tendency of late to spring up between urban and rural life.

The new Deputy Minister of Agriculture takes charge of the Agricultural Department at a most opportune time, just at a period when careful, sane leadership is required, because on account of industrial and economic conditions both at home and abroad, the industry of agriculture is facing a most critical situation. For instance such momentous problems as increased production and greater profit therefrom so as to hold people on the land, the eradication of contagious diseases of live stock, the acquisition of more skilled farm labor and the proper development of an export trade that will take care of our surplus live stock, grain and meat products demand immediate and vigorous attention. As a country we cannot afford to trifle with these matters any longer, and success or failure as meted out to us in the future will largely depend upon the action initiated now by Dr. Grisdale and sincerely followed by his officers in charge of the varous branches of the department. And in addition to all these things there needs to be a stronger chain of co-operation between department, farm press and people, without which we cannot possibly hope to attain the goal of our ambition.

The Maritime Farmer firmly believes that Dr. Grisdale fully realizes that there are weaknesses in his department, defective links which have held it back from developing full strength in the past, and that moreover, if given an absolutely free hand, he has both the ability and the courage to place it on a plane above criticism. The agricultural interests of Canada look to him to make an early start, and when he does he may count on loyal support and encouragement from every quarter.

THE NEW DIRECTOR OF FARMS

The new director of Experimental Farms, Prof. E. S. Archibald, assumes his position with the assurance that, backing him in the work, will be a Deputy Minister, who having himself been a director for eight years, fully understands what is really needed to make the system what it ought to be—a leader in the advanced movement for better agriculture. This should go a long way towards placing the Central Experimental and branch farms on a better working basis, and more able to cope with the growing demands of the country.

The appointment of Prof. Archibald will be popular throughout the country, and particularly with live stock men, in whose interests he has labored for some years with a great deal of success, as head of the Animal Husbandry Branch of the Experimental Farms' system. This line of work has taken him to all parts of Canada year after year, so that he is not only thoroughly in touch with the activities of the various branch farms, which now come directly under his supervision, but he also has a deep knowledge of farming conditions as they exist in the different provinces, whch will enable him to carry on the work effectively and efficiently. Coupled with this is the fact that he has always been a close student of rural requirements from an agricultural standpoint, so that his qualifications seem to eminently fit him for the work.

The farmers of Maritime Canada know Prof. Archibald's true worth and will congratulate him on his appointment.

CHEESE MAKING IN NOVA SCOTIA

The cheese factories should now be fairly under way for the season's work. A survey of the Province of Nova Scotia discovers only one factory in effective operation this year, the Malagash Point Cheese Factory, Cumb. Co., which has now been doing business some twenty-five years. This factory has been the means of developing one of the most prosperous sections of the Province. According to reports tabulated by the Provincial Department of Agriculture the average earning per patron in 1918 was $300.00 for the five months operation. The average earning of the Creamery patron over the Province for the whole year was $217.50. While it is to be borne in mind that there are detailed facts which modify this comparison, the figures are very striking, especially when the short season at the cheapest feeding period of the year is considered. The Provincial Dairy Division is satisfied that at present prices for dairy products cheese will give a higher net return than butter. The profit to the patron will be affected by the use made of the skim milk.

There can be no doubt that the major portion of the Province is better fitted for creamery work, but there are many sections where conditions are similar to those of Malagash, with a large cow population in a comparatively small area situated at a distance from the railway. In these localities, where there are, say, 300 cows within a radius of four or five miles, a cheese factory could be successfully operated during the summer months. It would take more than twice this number to make a successful creamery business. The initial cost of plant and machinery is much lower, and, in short the experience and knowledge of this Department go to show that a number of cheese factories could be successfully carried on in localities where there is now nothing doing. Any one who is interested and wishes further information should write to Mr. W. A. McKay, Dairy Division, Agricultural College, Truro.

THE MARKETING OF WOOL

The Canadian Co-operative Wool Growers, Ltd., was born at Toronto in February, 1918. It has proven a very vigorous child in the short period of its life to date. Last year it marketed upwards of 4,500,000 lbs. of wool, or about one half the total product of Canada. The prices paid ran from five to ten cents higher than those paid by other dealers, although many of these strained a point in order to bacle and discourage if not to kill the youngster organization. It is bidding for a bigger business this year, and it will pay every farmer who has wool to sell to remember The Canadian Co-operative. There is a depot somewhere within easy reach, and somebody who can give full information.

The explanation of the higher prices is not far to seek. The wool is prepared carefully for the manufacturer, thus commanding the highest prices obtainable, and middle men's profits are cut out. The method of payment to date is to advance about two thirds of the price at the time of delivery and to forward the remainder as soon as the wool is marketed, deducting only the actual selling charges. The wool is graded by Government graders, and is bought unwashed. The sole direction given out for the preparation of wool for this organization is to roll it up unwashed in separate fleeces tied with paper twine.

The capitalization of the Canadian Co-operative Wool Growers, Ltd., is $200,000, divided into $10.00 shares. Some of the stock is still on the market, and sheep men would be wise to take at least one share, so that they would have a real interest in the marketing as well as the growing of their wool. By the way, the organization guarantees 6% interest, and asks only 20% of the payment with application.

Mr. S. A. Logan, vice-president of the Co-operative and director for Nova Scotia, would be glad to correspond with interested parties. The warehouse for the Truro district is the Curling Rink, Truro, and letters may be addressed to Mr. Logan at the College, or simply, Truro, N. S.

STRIKING

An Irish soldier invalided home from the front was asked by a friend what struck him most about the battles he took part in.

"What struck me most?" said Pat. "Shure it was the number of bullets flying around that didn't hit me!"

Get a new Binder this year

It will be a real economy!

In these times of good prices for farm crops you should equip yourself with a Frost & Wood Binder to make sure of getting the utmost possible percentage of your crop.

It will be your best, most willing, most capable "Harvest Hand" for many years to come.

The easy working FROST & WOOD

Famous all over Canada for its light draft—due to the fine roller bearings at every friction point— its big capacity elevators and its ability to cut any kind of crop, light or heavy, tangled or straight. Drop into our nearest dealer's, sit on the seat of a F. & W. Binder, note the easy reel adjustments that bring every possible straw to the knives. See how accessible and easily understood every working feature is. Note its strength and splendid materials, and you'll say, with thousands of other successful farmers, "This is the Binder for me."

Write for illustrated Folder today.

THE FROST & WOOD COMPANY, LIMITED

THE IDEAL DAIRY BARN

(Continued from page 937)

operate, convenient, easiest to keep clean, cheapest and durable of any system yet devised.

Cost of Barns

The cost of building has advanced ni recent years but it costs no more to build a good barn and stable today than to build a poor one. The roof, walls and flooring are the same, but the difference between good and bad convenient and not convenient, all depends upon the planning of the interior arrangements. What then is the best way to go about it? That, of course, wil ldepend upon the individual, but the writer would urge all who are contemplating building a new or remodelling th eold barn to observe the following suggestions and act accordngly:

1. Obtain all the plans and information you possibly can. Write to the various barn equipment companies asking them for information and literature on the subject.
2. Visit all the good dairy barns you possibly can. Go out from your district and see what they are doing in other parts.
3. Don't be afraid to spend time getting the barn planned; it means much to you later on. 50 extra steps three times per day means 10 miles per year. Many barns have several of these 10 miles of walk built right into them. Don't you do it. There is plenty of work even in the most convenient barn.

INCREASED PROFITS IN DAIRYING THROUGH BREEDING BETTER COWS

(Continued from page 945)

Though some Canadian dairymen are far ahead of those in the Old Country in the work of producing high record cows, they fall behind when it comes to a matter of high average in a herd or the quantity of milk each acre of land can produce. A high average for the whole herd is their chief desire; the cow they pick out for testing is the one that is suspected of giving the quantity of milk that is not paying for her food and if she is found wanting she is fitted for the beef market.

The Cow's Individuality

It does not need an expert accountant to tell the dairy farmer that there is vastly more profit in one cow producing 300 pounds of butterfat per year than in two cows each producing 150 pounds butterfat during the year.

The most profitable cow is the one requiring the smallest percentage of feeed for maintenance purposes. The more milk producing the tendency of the cow is, the less quantity of feed given her will she use for maintenance; reserving that duty to her short dry period.

Individuality is instanced by two cows which were bred so that they calved only a week apart and kept under conditions which made a comparison of their performance most reliable. They were fed rations of the same composition and the amount of feed eaten by each was recorded. They were kept farrow and at uniform weights, and their production was recorded as well as the composition of the milk. The amount of feed required for maintenance was also recorded as wel as the percentage of feed digested by each. It was found that the better cow produced 8,522 lbs. milk during the year and 469 lbs. fat. The pooer cow produced 3,188 lbs. milk and 169 lbs. fat. Each required practically the same quantity of food for maintenance, and each digested equal percentages of the feed consumed. The better cow, however, consumed much alrger amounts of feed so that the percentage required for maintenance was only 35 per cent., while the poorer animal required 55.8 per cent. of her feed to keep he alive. In fact, the better cow ate 2.64 times as much as the poorer cow and produced 2.77 times as much butter-fat. It will be seen therefore that each cow made equally good use of her feed, but the better cow was a more efficient milking machine and was, in consequence, able to utilize a greater quantity of feed above maintenance than the poorer cow. The poor cow did not pay for her feed, while the good cow was a very profitable producer.

This is the crux of the whole question. Settle the fate of the scrub cow and the whole question is ended so far as profit in dairying is concerned.

Here is a Cletrac Fact — Kerosene Fuel!

IN operating the tractor fuel is an important item.

Gasoline is 36 cents a gallon. Kerosene (coal oil) is 18 cents.

The Cletrac Tank-type Tractor works on kerosene. Not just goes—but *works*—100%.

And the Cletrac uses no more kerosene than other tractors use gasoline.

On this cheap fuel the Cletrac will do a hundred things around the farm—do them quickly and well—save man-power and horse-power—save time and money.

Plow at 3½ miles an hour—the best plowing speed.

Pull a disc, harrow and drag over even muck land to the tune of 40 acres a day.

—*and never pack the soil.* The track-laying *Cletrac rides on top*—your seed-bed is perfect.

You'll want the active, dependable 12 h.p. of the Cletrac to haul stones and logs, grade roads, pull mower, binder, hay-loader and manure-spreader, or a string of wagons.

And you'll want the 20 h.p. of the Cletrac belt pulley to run your feed chopper, ensilage cutter, threshing machine, cement mixer, wood-saw.

Now is the time to find out about the Cletrac Tank-type Tractor. Write the Cletrac dealer or us for our book, "Our Owners Say," the story of what the Cletrac is doing for other farmers—told in their own words.

Ontario Experimental Farm,
Ottawa, Ont.

Messrs. Beach Motors, Ltd., 186 Albert St., Ottawa, Ont.:
Gentlemen—

I take pleasure in stating that the work done by you with the Cletrac Tank-type Tractor recently, on the Experimental Farm, Ottawa, was entirely satisfactory, either on plowing, discing or on belt work.

I might put particular emphasis on the satisfaction it gave in driving a No. 3 Massey-Harris Blizzard Blower in filling one of our silos; the power delivered was very even and the motor handled the work apparently with very little effort.

(Signed) D. D. GRAY,
Farm Superintendent.

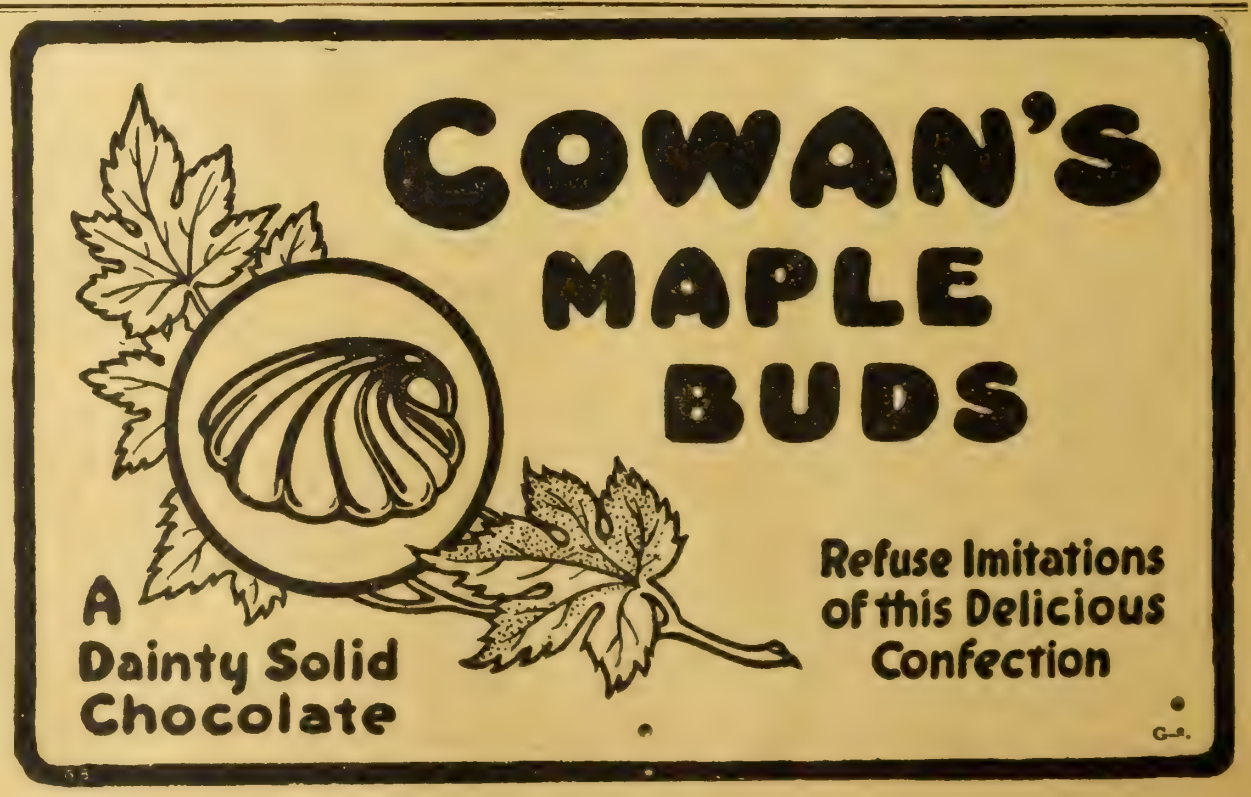
TWO OR THREE MILKINGS

For Holstein cows giving less than 40 pounds daily not enough is to be



gained by milking three times a day over twice daily to warrant the change. Cows giving 40 pounds or more will work more persistently, produce somewhat more largely of milk and test a little higher if milked more frequently than twice daily.

THE INFLUENCE THAT PROPER ATTENTION OF BROOD MARE HAS ON THE HORSE INDUSTRY

(Continued from page 949)

and the whole act only occupies five to fifteen minutes; and the animal is often eating quietly right up to the time of foaling.

It is very important to watch the behaviour of the mare at the first foaling, and to note all the preliminary symptoms already described, as it enables one to gauge more nearly the time she will foal subsequently. Mares should always be placed beforehand in a box stall, carefully disinfected, and the best way to have it bedded is to place six inches of good sawdust on the floor, and trusses of straw should be placed in the corners to prevent the mare lying down too near the corner and getting jambed. Seeing that parturition comes on so quickly it is always necessary to watch mares during the last day or two continually. The reason for this is a double one. The foal is frequently born with the membrane intact in which the foal is inclosed, and if not immediately released it will become suffocated. The mare, if in a loose box, and not too sick, will, generally, instinctively tear the membrane and liberate the foal. The second reason is that, if the foal is in a wrong position, the pains are so severe as to force the animal int othe pelvis in the wrong position, and it is with great difficulty that the foal can be removed. The foal must also be delivered within one or two hours after foaling begins, as by that time the membranes will have lost their connection, the circulation to the foal thus becomes disconnected, and death of the foal follows. A foal will rarely live through a three hours' period of foaling.

A pecularity among mares is, that some will not give birth to their young in the presence of persons if they can help it. If the birth is easy and normal, let both mare and foal alone. They wil come through the ordeal all right. The caretaker should always be on the watch to render assistance if need be, but the mare must not know of his presence.

PROPER WAY IN TREATING WOUNDS

The treatment of wounds must vary according to the nature and severity of the injury. Simple lacerations of the skin may be washed and cleansed by the use of a preparation of chloride of zinc, 10 grains to each ounce of water No bandages should be applied to simple skin injuries unless they are necessary to keep flies out of the wound.

A more serious and rather common injury results from the puncture of the foot by a nail, wire, or other sharp object. Should an accident of this nature occur the nail, if still in the foot, should be removed as soon as possible. A qualified veterinarian should be called promptly to explore the wound and proceed with suitable treatment.

Injuries to the skin in which the deeper tissues are involved, and from which abscesses or ulcers may or may not have developed, should be carefully washed out with a disinfecting solution for which 3 per cent. of carbolic acd, 1 to 1,000 bichloride of mercury, or 1 per cent. solution of potassium permanganate may eb used. Flaxseed poultices are sometimes of advantage on abscess formations after they have opened. After the wound is well cleaned a healing dressing, such as carbolized vaseline, or picric acid 2 parts, alcohol 40 parts, and water 400 parts, may be applied upon a pad of absorbent cotton, supported by a bandage. The bandage in these cases should be readjusted twice daily until healing has become established.

Medicines intended for fowls should always be prepared in suuh a manner that they can be given in a grain mash or in drinking water. Even those that have a disagreeable taste or odor will often be taken by fowls in their feed or water without hesitation.

Attention given to providing clean, dry staples for stock during those seasons of the year in which they are stabled continuously will have much to do in preventing such troubles as thrush and foul feet. Careful attention to feeding will prevent most cases of

A Correct Lubricant for every Farm Machine
There is an Imperial Oil man and a supply of Imperial Farm Lubricants near you. Both are at your service. That is why they are there.

Lengthen Engine and Farm Machine Life with Proper Lubrication

Durability and good service from each farm machine depend upon each getting oil exactly suited to it. If you are using Imperial Farm Lubricants, the high quality of your oils and greases is assured, but this is not enough. It is of vital importance that the **right** lubricant be used for each purpose and each machine.

The lubrication needs of a steam engine differ greatly from those of a gas engine. Different types of bearings—different machines—all require different lubricants. Knowing the right oils and greases to use, and using the proper Imperial Farm Lubricant for each machine, may save you the price of a truck or tractor. Imperial Farm Lubricants are available everywhere. Sold in one-half, one and four-gallon sealed cans and in steel half barrels and barrels.

IMPERIAL OIL SERVICE

Imperial Service clears up the subject of oils and there uses for you. The *Imperial Oil man* is ready to advise you on lubrication problems. You can consult him free, but his advice may be worth a lot of money to you.

bloating in adult cattle and scours in calves. Many feeders make the mistake of giving their young calves feed that has not been properly warmed, and troublesome diarrhoea results.

MARITIME FARMER'S AUTO SERVICE

If you're a Maritime Farmer subscriber we would suggest to you the advisability of availing yourself of the excellent auto service we are running. If you are like other auto owners, you have troubles, little ones and big ones. The Maritime Farmer places the services of Mr. Albert L. Clough at your disposal. It will not cost you a cent to place your problems before him and he will help you solve them. Mr. Clough is the editor of the motor service bureau of "Review of Reviews." Not only does he deal with your case, but in every issue of the Maritime Farmer he discusses other people's difficulties and his articles are doubtless applicable to your cast. Anyway, Mr. Clough is YOUR AUTO EXPERT and it is for you to avail yourself of his experience, if you care to. Write us and we will see that you are advised.

Not only are we doing that but when you want tires for your car, drop us a line. We can save you your subscription price many times over in a set of tires. We HANDLE NOTHING BUT FIRSTS. DO NOT CONFOUND THE TIRES WE SELL WITH THOSE ADVERTISED WITHOUT GUARANTEE AND WHICH ARE REALLY SECONDS. EVERY TIRE WE SELL HAS A STRAIGHT GUARANTEE OF 3500 MILES BEHIND IT, BY ONE OF THE LEADING MANUFACTURERS OF CANADA. There is NO STRING TO THIS OFFER. If you are a Maritime Farmer subscriber, the service is yours. Be wise and use it. DON'T DESPISE IT BECAUSE IT COSTS YOU NOTHING, BUT REALLY SAVES YOU MONEY.

THE CREAMERY PICNIC

What shall it be this year? A "blow-out" with all money gathered up going to supplement the finances of the Creamery, or a good social time, of which we have too few, coupled with some demonstration work in connection with the business. Some of the best picnics we have known took place in the neighbourhood of the plant which was kept running all day, with extra help from the Department to explain the different processes, and a strong social program interspersed with bits of information on Dairying and such topics. The meals were served in true picnic style. There was a fine, friendly, social atmosphere and everybody had a good time.

SHEEP DISEASE SPREAD BY TICKS

Over thirty years ago Principal Williams, of Scotland, agreed that louping-ill or trembling in sheeep was spread by means of ticks. For some time that theory was discrediteed. It is now brought into prominence by Sir Stewart Sockman. He has found that when a female tick has gorged itself with blood from a diseased sheep the larvae developed from the eggs of that female can infect new sheep with a disease marked by high fever, which sometimes ends in death.

A HANDY FARM BOOK

"The Veterinarian", by Prof. Charles J. Korinek, V.S., of the Veterinary College of University of Toronto, is a work that every farmer should have in his home. It is splendidly illustrated and deals in simple language with diseases of horses, cattle, sheep and swine. It tells a farmer what to do in a pinch and its possession may mean the saving of many dollars on hundreds of farms in the Maritime Provinces. The Maritime Farmer offers this fine work to its subscribers for seventy five cents, postage paid. We have hundred of requests coming to us every year for information as to treatment of live stock ills, which are fully dealt with by Prof. Korinek. Seventy five cents will help you greatly in becoming your own veterinary.

Glenrane Farm Holsteins!

WEST BATHURST - - - N. B.

FOR SALE !

We have an exceptionally fine litter of 13 (living) of our large Berks for sale @ $12.00, four to 6 weeks old. Ready first of June.

Owing to scarcity of labor and we not being able to see eye to eye with certain Gov. officials, as to the type of Shorthorn to raise, we have decided to go out of the breeding and raising of pure bred live stock. Therefore our herd of 40 head of Shorthorns will be sold between now and fall for either breeding or for beef. Parties wishing to buy, please come and see them. We have seven very nice bulls, 10 months to two years.

L. M. ANDERSON, Sackville, N. B.

KEEP Holstein-Friesian Cows

1. The Holstein-Friesian is a large vigorous cow, full of energy and abounding in vitality.
2. Her physical organization and digestive capacity are such that she is able to turn to the best advantage the roughage of the farm, converting the same into merchantable products.
3. She yields large quantities of most excellent milk, fit for all uses and especially suited for shipping purposes.
4. Heredity is so firmly established through her long lineage that she is able to perpetuate herself for the production of strong, healthy calves.
5. When for any reason her usefulness in the dairy is at an end, she fattens readily and makes excellent beef.

If you can't buy a herd, buy a heifer

FEEDS FOR SEASON 1919-20

The Maritime Farmer Has Arranged for Adequate Supply of Feeds for 1919-20--Get Busy and Have Your Society Buy Co-operatively

The Canadian Feed Manufacturing Company, of Fort William, the pioneers in the manufacture of feeds from elevator screenings, is preparing for a big year of "big business" in 1919-20. The comprehensive plant of the concern, a cut of which is published herewith, is now fully equipped to handle the great volume of business which was unexpectedly thrust upon it in its initial year. While the company's products were something new on the Canadian market, the demand for feeds last year induced live stock owners to try them out, and so gratifying were the results that the offerings of business came in faster than the mill could produce the goods, in its early stage of development. That condition, however, has disappeared and now any quantity of feed can be readily secured on short notice.

The Canadian Feed Manufacturing Company has behind it men who have grown with the grain trade of Canada. They are of the type that put Canada on the map in the grain business. They saw an opening for the manufacture of balanced feeds at moderate cost and they have invested a million dollars on their faith. The result is a manufacturing concern with one of the finest plants in America. More than that, it has behind it one of the greatest grain handling concerns in Canada. An auxiliary, in the shape of one of the largest elevating plants in Fort William, enables the Canadian Feed Company to do its business in a big way. It is doing that and the arrangements for this year's trade will enable it to cater to every want of the live stock man. Cattle, horses, hogs, poultry, etc., can all be fed from the mills of this enerprising Canadian concern, and it is Canadian.

At the invitation of the Canadian Feed Manufacturing Company, a representative of the Maritime Farmer went to Fort William to give the plant the "once over." He found a thoroughly equipped, modern factory. More than that the outfit is in the hands of men who know their business and in every department there was evidence that things were moving and in the right direction. The elevator capacity enables the company to carry raw material well in advance of its requirements. It is a big buyer and therefore protects its own interests and those of its customers. The plant is designed from an economic standpoint. There is no handling of raw material or finished product. From the time the grain arrives on either the sidings of the Canadian Pacific or the Canadian National Railways, until it is bagged and weighed, human hands have no part in the operation, except running the machines. Electricity is used for power purposes and the appearance of the plant at once suggests cleanliness and sanitation.

The production of the various brands of feeds put on the market by the Canadian Feed Manufacturing Company is attended by rather interesting processes. But the feature in which the Maritime aFrmer was most interested was that connected with the cleaning of the elevator screenings, which are used in the manufacture of Pioneer Feeds. The screenings are treated to a process of re-cleaning which removes all noxious weeds and foreign matter. Mustard seeds are parctically eliminated by this process. But if that were not sufficient the raw material is ground in specially designed machines which utterly destroy any possibility of germination.

When Pioneer feeds first came on the market every fellow who was interested got his axe sharpened. And each used it. All sorts of misrepresentation was indulged in. The feeds were represented as being made from weed seeds; they were alleged to be capable of every crime in the calendar that criminal feeds could perpetrate; but despite that they found sale and so excellent were the results that hundreds of farmers in the Maritime Provinces used them and intend to continue doing so. From men who have experienced the splendid milk and flesh producing qualities of Pioneer come testimonials of the highest character and these were backed up by orders for more of the same much maligned goods. But possibly there is no higher form of flattery than imitation and already some of the hardest knockers are getting ready to TRY and imitate Pioneer feeds. One thing that has been clearly demonstrated by the recent shortage of feeds is that animals will live and thrive without middlings, shorts or bran. Not only will they do that but they will perform their functions to better advantage on well balanced rations. This has been established to the satisfaction of not only those who have used a balanced feed within the last year, but has been demonstrated time and again by exhaustive tests conducted with the herds of the experimental farms of the Dominion. It has been proved beyond question that the most economical feed today offered on the market is elevator screenings and it is from this commodity that Pioneer feeds are being made.

Not only is this true but the Canadian Feed Manufacturing Company is producing for the live stock branch of the department Standard Stock Feed made from screenings. This feed is being sold to farm organizations at cost, but so great is the demand for it in Quebec and Ontario that none has found its way to the Maritime Provinces. And more than that, the department af few weeks ago had orders on hand which would keep the two mills going to capacity for days. This branch of the live stock department's work will be dispensed with when the stocks held by the government is exhausted. The Canadian Feed Manufacturing Company, however, will continue to manufacture from the same formula, their Standard Pioneer. The Maritime Farmer is pleased to announce that it can supply this and other feeds manufactured by the Canadian Feed Manufacturing Company to farm organizations. Last year we handled over 100 cars of these feeds in the Maritime Provinces. We have no hesitation in saying THAT THE RESULTS WERE HIGHLY SATISFACTORY. IF YOU HAVE ANY DOUBT ON THIS SUBJECT WE WILL FURNISH YOU WITH NAMES OF THE BEST FEEDERS IN THE MARITIME PROVINCES, WHO WILL GLADLY TESTIFY TO THE FINE RESULTS OBTAINED BY USING THESE FEEDS.

NEVER MIND THE KNOCKER. The only people who had complaints to offer last year about Pioneer Feeds were people who did not see them, or dealers whose profits were cut so law that the operation hurt. Every effort has been made to defeat co-operative buying among farmers but the thing will not down and all the knocking will not detract one iota from the feeding values of Pioneer feeds. If your are interested the Maritime Farmer will furnish you with full particulars as to how to buy, prices, etc.

Selling Pioneer Feeds

This is one of the features of Canadian Feed Manufacturing Company's business which must commend itself to every wise buyer of feeds. These feeds are offered with a guaranteed analysis as to protein and fat. They are sold on their actual feed values and not on any fictitious or imaginary content. If you are a well informed buyer of feeds you will always insist upon knowing just how much protein and fat are carried in any feed you contemplate purchasing. Don't be misled by THE APPEARANCE OF FEED. That will tell you nothing of its real feeding value. Last winter farmers in the Maritime Provinces paid hundreds of dollars more for single cars of feed than the stuff was worth. The Canadian Feed aMnufacturing Company is not afraid to have its feeds bought and sold on the basis OF ACTUAL FEEDING VALUES.

Elevator screenings Standard feed as supplied by the Department of Agriculture, Ottawa, tests as follws:

Chemical and Botanical	
Protein 14%	Broken Wheat..46.1 %
Fat.... 5%	Oats..... 1.0 %
Fibre.. 8%	Flax ..... .1 %
	Wild Oats 10.65%
	Wild Buckwheat 35.15%
	Mustards ..... .7 %
	Other seeds.... .65%
	Chaff 5.65%

While the botanical composition may vary to a slight extent, the percentages of protein, fat and fibre will remain almost constant and, consequently, the feeding value will change but very little.

Other feeds supplied by the Canadian Feed Manufacturing Company are Pioneer Hog, Pioneer Horse, Pioneer Molasses Dairy and Pioneer Fat Maker. The latter is intended for beef cattle raisers and is specially manufactured for their use. Ground Special is another produce of this mill. It is a lower grade feed. Some feeders prefer it to any other feed they bought last season but it is better to mix it with other feeds. It is slightly bitter in taste but its low cost and its comparatively high protein-fat content have induced many well known dairymen to use it in large quantities. Many are outspoken in their preference to it, as compared with bran.

Other Feeds Available

It will be possible to secure mixed cars of all the above mentioned feeds, together with any kind of whole grain, barley meal, corn meal, cracked corn, poultry feeds and supplies, oil cake, etc. All oats will be sold subject to standard samples. The Company proposes to reclean all oats sold and will stand behind their goods. The prices of feeds of standard quality are almost fixed, but they will vary from time to time. Other commodities are sold subject to price confirmation on date of order.

The Maritime aFrmer is now preparing to supply feeds for 1919. From time to time announcements of interest will be made in these columns. The wholesale prices will be quoted in every issue of the Maritime Farmer's market report. It will be at these prices that you can buy. We would again impress upon readers the reliability of Canadian Feed Manufacturing Company's products. Our representative has been there and knows whereof he speaks. The Maritime Farmer is willing and anxious to help farmers get their car-lot supplies at cost. We can help you do that. WE SAVED TENS OF THOU-

Gleanings From the N. S. Department of Agriculture

CLOVER SEED GROWN IN N. S.

For several years the N. S. Department of Agriculture has consitently followed a policy of encouragement to the growing of clover seed. A huller was purchased and offered for use to any community which would produce a reasonable quantity. This was supplemented by an offer to pay 50% of the cost of any hullers bought by private parties or local organizations. A group of farmers here and there took advantage of these offers and attained satisfactory results. Last year a field crop competition in clover growing took place in the County if Inverness, and some very high scores were recorded. But, over the Province as a whole, there has not been a very general response to the Government policy until this year. Last Spring clover seeed was 60c and over per lb., and difficult to obtain at any price. The natural result is a light sowing of clover, and that in the best season for some years for a good catch. So farmers all over the Province are realizing that something must be done to meet the situation, and numerous enquiries have lately come to the Department.

Now the growing of clover seed is a very simple matter. Two methods are followed with success. One is to allow the first crop to mature without interference, to cure and store it in the usual way until thrashed. The other is to cut the first growth early, about the last of June or the first of July, the earlier the better after a fair stand of grass has developed. Then the second crop is allowed to mature. It is cut when the blossom has turned black, which in this case may be in October, and stored in the usual way. This latter is the more satisfactory method. There is less alien matter and usually a heavier yield of seed. In selecting a field, if the first crop is to be matured a lighter stand should be selected so as to avoid too much bulk of other matter. If the second crop is determined on, the richest plot should be selected so that the growth may be as rapid as possible. Very little loss in fodder is suffered, and the yield of seed runs from 100 lbs. to 600 lbs. per acre, at this year's prices a value o ffrom $60 to $360.

It is not the direct financial return, however, that should be the chief factor in the case. Clover, as is well known, is one of the best soil builders we have, in addition to being one of our best fodder plants. There will never be enough sown until it is grown at home. Persons wishing further information should write to the Department of Agriculture at Truro.

ORCHARD PESTS

The Forest Tent Caterpillar has appeared in immense numbers in the northern sections of Colchester and Cumberland Counties. This is a large hairy caterpillar about two inches long when full grown, and marked with a row of cream colored spots along the middle of the back. When numerous, as on this appearance, these will strip whole trees, then descend in an army and treat adjacent trees in the same fashion, and it is not strange that they should be mistaken by the uninitiated for the "Army Worm." The caterpillars are at this time of year almost mature, and wil soon spin their silken cocoons in curled leaves or other sheltered situations, emerging after three weeks as small brown moths with two dark bands acros the front wings. In another month these moths will be seen flying about lighted windows at night. They, in turn, lay their eggs in masses of 150 to 400 in the form of a ring around twigs of trees and shrubbery, covered with a greyish froth. The caterpillars emerge in the Spring when the leaves are breaking out.

Orchards that are regularly sprayed have little to fear from the Forest Tent Caterpillar. In this invasion it is confining its attention to forest trees for the most part. Where special measures are necessary, however, spraying with arsenic of lead should be resorted to. For the newly hatched caterpillars a strength of two pounds to forty gallons is sufficient, but when they are half-grown or more double this strength is necessary. To protect uninfested trees from migrating caterpillars, banding with tree tanglefoot is the recognized remedy.

A first cousin of the above variety is the Orchard Tent Caterpillar, which is distinguished from the other in appearance by a yellowish stripe down the back in ploce of the row of dots, and in habit by its weaving of its tent in the fork of a limb. This pest is much in evidence this year. It may be destroyed in a similar manner, or by cutting out and burning the tents, or by burningout with a torch when all the caterpillars are at home.

The "Canked Worm," a looping caterpillar, at first green in color, later turning dark, is also the cause of much complaint this season. It has not only stripped many orchard trees of their leaves, but also such wild trees as oak and maple. Light infestations are easily handled if taken in time, the 2 lb. mixture as above being sufficient if applied before the blossoms open. The strength must be doubled or eoen more, up to 5 lbs. to 40 gallons, in case of heavy infestations, or late application.

Such outbreaks as these are always liable to occur until spraying becomes a part of the regular farm practice. Arsenate of lead is the safest poison for general purposes. The cheapest poison at present is arsenate of lime, which, however, should not be used alone on apple foilage, but only in conjunction wfth Bordeaux mixture or five times its weight of water-slaked or hydrated lime. Arsenate of lime can be safely and economically used on potatoes and other trucn crops. Paris Green should never be used on fruit trees.

WOMEN'S INSTITUTES

Many women's societies organized for war work and patriotic purposes are now contemplating carrying on under the Institute plan. This is a good wholesome tendency. There is abundant room for patriotic activity still, deadly foes to be overcome, and greatly needed reforms to be thought through and carried out.

The new Superintendent of Institute work, Miss Helen J. McDougall, who has made a name for herself in the same department in the Province of Manitoba, takes up her work in Nova Scotia the first of September. The Provincial Institute, which has usually met early in the summer, has been postponed until the Autumn so as to have Miss McDougal present. In the meantime the Secretary for Agriculture will be glad to correspond with interested women in any community who think of organizing on the Institute plan.

AN EGG LAYING CONTEST

The contest idea which has worked well in stimulating people to adopt the best methods and secure the best results in other branches is now being carried in earnest into the realm of the hen. One of the humblest of man's servants, she is also coming to her own. Market prospects for her products are very bright to everybody except the consumer. Canada has never been able to do much more than supply her own need along this line, and seldom has she even done that itself. So there is vast room in this granary of the world for new interest and enterprise in this department.

Having in mind the present and future situation,, the Poultry Division at the College of Agriculture, Truro, is arranging for an egg-laying contest to run from the first of November, 1919, until September 30th, 1920. The conditions of the contest have been published in fuller form elsewhere. Any one who is unable to lay hands on the rules and regulations would do well to write Mr. J. P. Landry, Truro, N. S. It is sufficient to say here that plans are being made for 30 pens of fiv efemales each to be kept, fed and cared for at the College, throughout the period mentioned. The first 30 ogering, if they conform to the conditions, will be accepted. The birds will have expert handling and care, and good prizes will be offered for the competition.

Haying

(Experimental Farms Note)

The cutting and curing of hay is an operation requiring the exercise of prompt action and judgment if a maximum yield of hay of suitable quality is to be saved. Toward this end there are several factors which should receive consideration. The time or stage of cutting is of prime importance since it affects both yield and quality. Usually the most profitable yield is obtained when the crop is cut when in blossom or just past that stage, say when about one-thir of the bloom has disappeared. Ordinarily the tendency is to leave the commencement of haying too late for proper curing during the latter part of the season, due to over ripeness of the croj. It is advisable, therefore, to plan to do this work during the period when there is the least possibility of loss. Beginning haying early is good practice. Clover and alfalfa cut slightly immature will make better hay under favorable weather conditions than left until fairly ripe. Besides, an early start will allow for loss of time through broken weather during the haying season and will ensure a heavier second crop which may be utilized for hay, seed and pasture purposes.

With regard to methods of curing, no definite rule or rules of procedure can be laid down to meet all requirements. A successful hay maker so to speak "Knows his business," a knowledge that is acquired only by long experience with vagaries of weather, periods of cutting, conditions of curing, etc. To become efficient in this work requires one viligant and with abilit yto contend with emergencies.

Clovers and alfalfa are more difficult to cure than timothy and other grasses. They are more succulent, absorb rain more readily and the leaves, the most valuable part of the plant, are more easily broken off than the leaf blades of grasses. They should be cut when free from dew or other moisture, and dried for placing in cocks, by the agency of wind rather than sun as far as possible. Exposure to rain or even heavy dew will change the green leaves to dark brown and make them crisp and readily broken og by handling. Rain and dew will also extract the aroma of fragrance, a quality esential in making hay palatable and attractive.

Mixed hay, timtothy and other grasses, cure more readily than clover and are not affected to such an extent by unfavorable weather conditions. Otherwise the general principles of curing laid down for clover and alfalfa apply. Timothy grown for market purposes may be cut at a later period than is recommended for ordinary farm feeding purposes. Market conditions demand well matured. though not over ripe hay.

N. B. Cheese and Butter Board Organize

On Thursday afternoon the 12th ult. an organization was affected in Sussex that will be of far reaching benefit to the cheese and butter makers of New Brunswick and the buyers throughout the Maritime Provinces. It wil lbe known as "The New Brunswick Cheese and Butter Board." Representatives were present from practically all the cheese factories, and it was the unanimous opinion that it would be greatly to the advantage of all interested to have a "Cheese Board" that would meet at regular specified dates, and at which meetings the output of the different factories could be boarded and disposed of to competitive buyers.

After the matter had been thoroughly discused, it was decided to form an organization to be known as "The New Brunswick Cheese and Butter Board" and the folowing were elected as Board of Directors for the ensuing year:

President, T. G. Perry, Butternut Ridge.

Vice-President—O. W. Keirstead, Collina.

Secretary—H. W. Holeman, Sussex.

And as additional members of the Board of Directors—R. H. Pearson, Beleisle, and W. S. Mason, Head of Millstream.

After the organization had been completed, the new Board at once proceeded to business and five hundred cheese were boarded.

These were disposed of at 29.8 cents.

The buyers present were R. B. Colwell, Halifax, N. S.; Mr. Kennedy, of Gunns, Limited, Mr. Akerly of Swifts Canadiian, and representatives from the G.E. Barbour & Co., and Baird & Peters, St. John; and F. P. Reid & Co., Moncton.

The meetings of the Board will be held hereafter in the basement of the Agricultural School Building, Sussex, on the afternoon of the second and fourth Wednesday's of each month.

The formation of a cheese Board will bring factorymen together at regular intervals to discuss affairs, and will greatly expedite business in general. The old way of doing was for the buyers to write from Halifax or somewhere else to the factory and enquire how many cheese were on hand and the price asked for same; this letter would usually remain a day or two before being answered and by the time it reached the buyer and the purchase completed, the whole condition of affairs might probably be changed

and the markets entirely different.

With a Cheese Board a new condition of affairs is brought about and the slow unbusiness methods of the past will be suplemented by competitive buying and uniformity of prices.

Another great advantage is that it will bring the buyers and the sellers in personal touch and differences can be readily adjusted and future business gone into.

Having the Cheese Board meet in Sussex will be a good thing from a town standpoint, as it will bring here twice a month, representatives from factories all over the Province, and our merchants will no doubt reap quite a business harvest, as will our hotels and restaurants.

Buyers from all parts of the Maritime Provinces and elsewhere will also attend the meetings of the Board.

The New Brunswick Cheese and Butter Board owes its existence greatly to the efforts of H.W. Coleman, the energetic Dairy Superintendent of the N. B. Dept. of Agriculture, who has his headquarters in Sussex. Under Mr. Coleman's practical guidance, the cheese makers of New Brunswick are making rapid strides toward manufacturing cheese of a uniform quality and equal to the Ontario product. He is the right man in the right place and the N. B. Government was very fortunate in securing his services.

SECOND MEETING OF THE N. B. CHEESE AND BUTTER BOARD

The second meeting of the New Brunswick Cheese eand Butter Board was held in the Agricultural School building, Sussex, on Wednesday afternoon, 25th ult. A large number of factory representatives were present and the buyers in attendance were R .B. Colwell, Halifax; Mr. Akerly, of the Swift Canadian; Mr. Bonnel, of Harris Abattoir; Mr. Lyman, of Northrup & Co., St. John, and Mr. Robertson, of F. P. Reed & Co., Moncton.

Mr. Colwell started the bidding and called the Board at 29 cents with no sales. Mr. Akerly made four calls—29.6, 29.8, 29.7, 30. Mr. Robertson bid 30 and got first call. Mr. Colwell also bid 30.

The factories having cheese boarded and the number of cheese were as follows, all of which was sold at 30 cents per lb. f.o.b. nearest Railway station to factory:

Factoriese	No. of Cheese
Havelock	180
Lower Ridge	124
Cornhill Corner	75
Cornhill	285
Newtown	36
Killam's Mills	50
Lewis Mountain i	50
Manhurst	50
Mt. Middleton	50
Carsonville	62
Hd. of Millstream	65
Berwick	60
Collina	120
Pearsonville	77
Belleisle	160
Hammond	35
Total	1479

The average weight of cheese sold was 70 pounds each, so it will be seen that 1479 would make a total of 103,530 pounds, and at 30 cents a pound, would mean $31,059, a tidy little sum that will come into Kings County in the near future.

The buyers bought from factories as follows: R. B. Colwell—75 from Cornhill Corner, 50 Killam's Mills, 50 Lewis Mountain, 65 Head of Millstream, 60 Berwick. 80 Belleisle. Mr. Akerly for Swifts Canadian—124 Lower Ridge, 85 Cornhill, 120 Collina, 35 Pearsonville. Mr. Bonnell for Harris Abattoir—200 Cornhill, 80 Belleisle, 36 Newtown. Mr. Robertson for F. P. Reed—50 Mannhurst, 50 Mt. Middleton, 62 Carsonville. Gunn's Ltd., by request at Board price—180 Havelock, 35 Hammond.

The next meeting of the Board will be held on Wednesday, July 9th.

United Fruit Growers Hold Annual Meeting

(Kentville Advertiser, June 27.)

The most harmonious and satisfactory meeting in the history of the United Fruit Companies was held at their new offices, Webster St., Kentville on June 7th. An unusually large number of delegates were in attendance all of whom seemed well satisfied with the year's business. The turnover of the past year has been the largest in the history of the organization, amounting to about two million dollars and handled at an overhead cost of 1.31 per cent.

President F.W. Bishop was re-elected by acclamation as were the two retiring members of the board of management. The officers of the company now are:—President F. W. Bishop, Vice-President E. H. Johnson, agement C.W. McKeen, T. L. Harvey, V. B. Leonard, F. B. Johnson

It is eight years since the United Fruit Companies were organized. The years during which they were growing from a loose organization of a few companies to the large and well equipped organization of 43 subsidiary companies were dark years for the Nova Scotia apple growers. High costs and poor prices were causing much hardship among apple growers and out of sheer necessity they organized and through cutting costs in buying supplies and selling so as to have as few handlers as possible between them and the consumer have turned losses into profits. During its career many subsidiary companies have temporarily dropped out and Secretary K. L. Pineo, Board of Manmany individuals in turn have temporarily dropped out from the local companies. Almost invariably this company or the member has returned to the organi ation after an unprofitable lesson.

The United has been the main factor in causing the orchards of the Annapolis Valley to now be in the superior condition that they are. Through making profits for them during the hard years since 1912 which would, without their organization, have been losses. The major portion of the success of the United has been due to their fortunate selection of their manager, A. E. McMahon. During his years of service with the United, in various capacities, he has not only proved himself a skilful salesman, but a buyer of unusual ability, as is proved by the fact that the United now sells in many places lines to firms from whom they formerly purchased the same lines. With the membership of the United both in companies and individuals now larger than ever before and knowing that the darkest days for the apple industry in Nova Scotia are now over, and with their organization now in good shape, the future is certainly most encouraging for the membership.

Pig Pastures

The cost of production of pork can be materially reduced by the use of pastures. Under ordinary conditions where a pig is fed on grain alone, it takes careful feeding and a very thrifty kind of pig to make 100 pounds gain from 500 pounds of grain, and more frequently 600 to 700 pounds of grain are consumed. Experiments with pasture and self feeders at Brandon Experimental Farm have shown that it is possiblt to make good gains at the rate of 300 to 400 pounds of grain to the 100 pounds of pork with the addition of pasture. Pasture cannot be used satisfactorily to replace grain, but it may very profitably reduce the grain consumption by one-third . As the pasture can be grown very cheaply and the pigs do the harvesting themselves, the cost of producing a pound of pork may be reduced 20 to 25 per cent. This may mean the difference between profit and loss.

There are a considerable number of crops that may be used for pig pasture . The ordinary grain crops such as wheat, oats, barley and rye are quite suitable. Sown in the spring, these crops are ready for pasturing at the time that spring pigs born in March and April are old enough to use pasture to advantage. Spring rye is the first of these crops to be ready to use. The pigs eat it well and produce good grains on it. However, it soon passes the most palatable stage and becomes more woody as it shoots into head. Oats and barley are about a week later than rye in reaching the proper stage for harvesting but are relished rather more by the pigs and continue in a suitable condition for pasturing for a longer time. Wheat also produces good pasture but is no better than other grains and the seed is more expensive.

For later summer and fall pasture, there is nothing better than rape. Sown in early spring it is ready for pasture about the middle of July, or, if sown later, it reaches pasturing stage in about six weeks from the date of sowing. Pigs like it very well; it produces a large amount of feed and stands pasturing well. It is one of the best plants for hog pasture.

Another good fall pasture is fall rye. If sown in midsummer it is ready to pasture in a month from the date of sowing. It produces a good grade of pasture until severe frosts come and does not head out in the fall.

Perennial crops may also be used as pig pasture. Alfalfa will produce more pasture per acre probably than any other pasture crop. Pigs do very well on it, and produce economical gains. However, it costs more to start with alfalfa as the land must be prepared two years ahead and sown one year ahead of the time it is to be used. Also, its greatest growth is in May and June when on the average farm there are few pigs to use pasture as the spring litters are too small, and very few fall pigs are raised. The second crop of alfalfa comes in well for later summer pasture for spring pigs. Pigs root out alfalfa and soon destroy it if allowed to. It is advisable to put rings in their noses when they are pastured on alfalfa.

The ordinary grasses such as brome and timothy make first class pig pasture in the spring months. But, as in the case of alfalfa, there are usually not many pigs to use pasture at that time. In midsummer and fall when pigs need pasture most, the grass pasture is often dry and harsh and not suitable for piigs. Consequently, better results are usually obtained from the annual crops first described.

Pastured pigs should be confined to pens for a few weeks at the last before shipping to market. While on pasture, they take a great deal of exercise, especialy if of the more active breeds, and as a result grow well and make good frames with plenty of lean meat but may not put on enough fat. By shutting them up for about three weeks at the last, they make amazing gains in weight, thus increasing the profit, and get into a more finished condition for market. Pigs of the more sluggish breeds may be finished on pasture.—W. C. McKillican, Superintendent, Experimental Farm, Brandon, Man.

New Stock Import Regulations

The Dominion Department of Agriculture has found it necessary to amend the regulations governing the importation of American cattle for exhibition purposes.

After July 2nd it will be necessary for all American cattle imported for this purpose to be accompanied by a tuberculin test chart signed by an officer of the United States Bureau of Animal Industry stating that they have been tested by him within sixty days of the date of entry at the boundary.

This amendment was considered advisable owing to the fact that changes have been made in the American Regulations which now require that Canadian cattle shipped to the United States for exhibition purposes, must, after July 1st, be accompanied by a tuberculin test chart signed by a veterinary inspector of the Health of Animals Branch of the Department of Agriculture, stating that they have been tested within sixty days of exportation.

Live stock exhibitors should bear this in mind, and forward requests to the Veterinary Director-General, Ottawa, for the services of inspectors to test their cattle as promptly as possible after they have decided to ship them for exhibition purposes to the United States.

EXHIBITION DATES

St. Stephen	Sept. 9th to 12th
Woodstock	Sept. 9th to 12th
Fredericton	Sept. 13th to 20th
Chatham	Sept. 22nd to 27th
Charlottetown	Sept. 23rd to 27th
Port Elgin	October 1t and 2nd
Maritime Winter Fair, Amherst, N. S.	Dec. 15th to 18th

The farmer and dairyman who uses skim milk as a basis for the protein element of his feed for pigs or calves will not require to purchase so much protein on the market.

THE MARITIME FARMER

And Co-operative Dairyman
Registered Trade Mark

Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definite order for discontinuance is given.

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsible advertisers. To take advantage of this guarantee, written complaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said:—"I saw" your adv. in the MARITIME FARMER.

RATES FOR CASUAL ADVERTISEMENTS.

Contract rates on application.

BUYING FARM EQUIPMENT

With the market teeming with new or improved types of farm machinery, all designed with the one prpose in view—labor economy; with present values at skyline limits, and a period of more or less uncertainty in prospect, the art of buying carefully, of investing to good advantage, is more than ever essential to the farmer, who is running his business on modern progressive lines. Farmer-investors, good and bad, may be divided into three well defined classes. In the first class is represented the individual, who, when he runs across a piece of equipment that takes his fancy, simply buys it on the spur of the moment without a thought as to the cost, or adaptability to his particular line of work. When he gets it, he behaves very much like a boy with a new toy—super-enthusiastic for a few days and then promptly forgets all about it. This sort of business is satisfactory to neither buyer nor seller, and the reader can form his own idea as to the wisdom of such a method of making investments.

In the second class comes the man who goes the limit in the opposite direction, working on the pennywise principle. He runs across a new machine, which suits him so far as quality is concerned, and gives every indication of being all he has been looking for. He can see quite well where it can be of advantage in his business, but when the price is mentioned—presto! Everything looks different. It does not make any difference, though he may see quite clearly where he could save the cost of the thing several times over—it is all the same—the price is too high, and there the matter ends. More often than not this man falls into the hands of the wily agent, who has an inferior article to sell at a low price, and he winds up by getting an article that suits his purse, but not his purpose.

But in the other class is the farmer who places his money to the best advantage, going about it very differently than either of the other two mentioned. When the proposition of purchasing new equipment of any kind is put up to him, it must be accompanied by all particulars, including cost. If there is a chance to see the machine he is planning to buy at work under conditions resembling those which prevail in his own business, he makes every effort to see it, and judge for himself as to its merits. Then finally before deciding one way or the other, he carefully balances cost against reasonable returns, in order to be sure that his investment will have a sound financial basis. Business transacted after a careful study of this kind is satisfactory to both parties; the buyer is satisfied with his purchase, and the seller gains another good customer.

WANTED—COMMUNITY LEADERS

Every rural community should have one or more leaders of thought and action. There should be at least one intelligent and fairly educated man in each district to accept the responsibility of leadership in all progressive ideas. Around such a man many organizations can be built—fruit-growers, stock-breeders, farmers' institutes, etc., providing he can find sufficient time to act as secretary, and conduct an outside correspondence which will command attention and respect. Men of the desirable stamp are usually to be found in every district, but are geenrally of a retiring and unpretentious disposition, requiring some urging in the commencement to undertake such work.

Of course every community has its would-be leaders and leaders backward—blattant creatures, bigots (religious and otherwise), selfish, vain and ignorant. The noisiness of such should be ignored. Men of firm ideas with such ideas reasonably based, should be chosen as leaders; but when found they should not be smothered in work. It is well to rememoer that such men have their own farm work to attend to, and anything they do for the community is either out of private spare time, or to the detriment of farm work. Every natural leader is a natural worker, and his probable ability in leadershrip can be measured by what he has accomplished on his own place. His services, when rendered should not no unappreciated. If at all possible, some regular monthly money remuneration should be made. If this is not possible, the men of the district could occasionally get up the old fashioned "bees" of Ontario and New Brunswick. These old fashioned gatherings never fail to produce lasting results and are one of the most pleasant forms of social intercourse in rural communities.

Solid worth in the man, sincerity, unselfishness and intelligence are the great essentials in the selection of community leaders. On no account should such a man be condemned on account of either his politics or his religion.

DESTROY THE WEEDS

"A stitch in time saves nine". This is espeo ially true in the case of weeds. When one considers that a single specimen of many kinds of weeds may produce over 10,000 seeds, and that many of such seeds may be blown far and wide by the wind, one begins to realize just what a source of contamination is a weedy roadside, a fence corner of a waste place, says Prof. J. E. Howitt, of the O.A.C.

It is too common a sight in the fall of the year to see a farmer busy with his fall cultivation, attempting to clean his field and preparing a good seed bed for next year's crop. At the same time on the roadside near the field or in the fence corners or some waste place near it, such weeds as perennial sow thistle, Canada thistle, milkweed and wild lettuce are maturing seeds by the thousands, to be blown on to his well tilled field and dresed with enough filth to markedly lessen his crop and increase his labor next year.

When labor is so scarce and when the maximum quantity of grain should be produced from every acre under cultivation, no can can afford to allow seeds to seed anywhere in the neighborhood of his farm. A few hours spent now and again during the summer cutting weeds on roadsides in waste places and fence corners is a good investment for the future, which will pay handsome dividends in labor saved and increased crop.

FEED AND SALT REGULARLY

A cow is pretty much a creature of habit. She becomes accustomed to getting her feed at a certain time each day and if that time arrives without the feed she worries about it and this has a tendency to affect her milk production. For this reason regularity in feeding is very important. Also waterng and salting should be attended to punctually. And the water should be good. It is a mistake to require cows to drink tainted water, for it certainly impairs the health if it does not affect the quality of the milk. The man who provides properly for the wants of his cows has a right to expect that they will repay him in a more abundant milk flow.

DRAINAGE VS. GOOD ROADS

It is possible to make good earth roads but they must be well drained. But for that matter. roads of any kind cannot be made good without drainage. Roads must not only have good surface drainage, but they must also have good underdrainage. Surface drainage is secured by proper grading, adequate side ditches and by keeping the crown of the road properly dragged. Where the road does not dry out quickly lines of tile should be laid. It is important that the earth road be kept in good condition by a liberal use of the drag. To get best results use the drag after each rain. Wait until the road surface has dried slightly but when it is still wet enough that it will not crumble but will smear. Go down one side and back the other. This will drag a thin layer of earth to te centre and give the road a crown that will sed the water. To keep roads in proper condition they must be given constant attention.

PLANT LICE AND SPRAYING SOLUTION

What will destroy the small lice that get on the leaves of apple trees; also where can I get lime sulphur solution for spraying? J. A. B.

There are several good remedies for insects of this type. A very good commercial solution is nicotine sulphate, commercially known as Black Leaf 40. This can be purchased from any seed firm. Full directions for using the remedy are given on each container. Kerosene emulsion also is a remedy, and may be made at home as follows: Mix a small quantity of coal oil with a thick suds of castile soap, made with hot soft water. This solution should be diluted with eight to 10 times its volume of water. In spraying apple trees or any plants for aphis or green fly, be careful to spray the underside of all leaves, as most of the lice will be found there.

* * *
* * *

Every farmer should keep some sort of account system of his business. It should show the profit and loss of all his operations.

* * *

The end of the war failed to bring the slump in the cost of living which most people felt sure would follow.

CANNING :: By Frances Low Smith in Modern Priscilla

The past two years have seen home canning placed on a simple, scientific basis that is as easily followed by the girl of twelve, as by her mother. Before the war, rarely did a woman attempt canning meats or veegtables. To-day she puts her products in the canner with the same assurance that she puts her bread in the oven.

There are several processes in use, but the simplest, safest, and cheapest for home use is the cold-pack or hot-water bath, as it is sometimes called. The outfit may be purchased, or improvised from utensils in hand. It includes the following articles:

A large receptacle such as a wash-boiler, a fifty-pound lard-can, or a large pail with a tight cover; a wooden or wire rack which fits the bottom of canner, and allows the water to circulate freely under the containers; and a jar lifter, or one of the wire baskets divided into compartments for the jars.

Glass jars or containers are the most satisfactory for home use, and preferably those having glass tops, although screw-tops may be used safely by renewing whenever they become defective in any way, and by always using new tops for meats and vegetables. Bottles that have contained olives, peanut butter, catsup, and other commercial goods may be saved to use for pickles, juices, jellies, and similar products. Seal wtih sealing wax or paraffin.

Rubbers should be of the best quality; those that will bear the long boiling without deteriorating. It is said that 75 per cent of spoilage in home products is due to poor rubbers. Use them only once.

Special Directions for Vegetables

Add one teaspoon salt to each quart of vegetables; also two or three teaspoons sugar to such vegetables as corn, peas, and carrots. Cabbage. greens of all kinds, and string beans are often improved by the addition of a slice of salt pork, ham, or bacon.

A cup of vinegar, two or more tablespoons sugar, and two teaspoons pickle spice, added to one quart of young carrots or beets before filling jar with hot water, makes delicious pickles.

A combination of vegetables, such as succotash, corn, and tomatoes, or peas and carrots, may be canned in order to utilize left-overs. or to vary the canned products. Be sure to sterilize sufficiently. For instance, if corn and tomatoes, boil the length of time required for corn.

Vegetable Greens.—This class includes spinach, chard, dandelions, and other greens; and such vegetables as cabbage, Brussels sprouts, cauliflower, and green peppers. Can the day they are picked. Trim greens, and remove old or coarse leaves. Wash very thoroughly in two or more waters to free from sand and dust. Place in cheese-cloth and blanch in steam so as to retain the mineral salts and volatile oils that would be lost if blanched in water. Soak cauliflower and cabbage an hour in cold brine (½ pound salt to 12 quarts water) before blanching.

Root and Tuber Vegetables.—In this class are parsnips, beets, carrots, turnips, kohl-rabi, and sweet potatoes. Scrub well with a vegetable-brush. With beets leave an inch of stem and all the roots, while blanching, to preserve color and sweetness; also with young carrots. Beets will look faded when removed from canner, but in a few days will regain their color. Scrape or pare to remove skin. Kohl-rabi and turnip must be pared on account of the thick skin. Cut vegetables in slices, quarters, or cubes, or can whole.

Tomatoes.—Scald one minute or long enough to loosen skins, and cold-dip quickly. Peel, remove stems, and cut in halves if too large to go in jars. Pack closely, pressing down with a spoon. Add no water. Season with salt and sugar if desired. Complete process as for other vegetables. Imperfect tomatoes may be pressed through a strainer, and canned for soup or sauce. Blanch, peel, remove stems, cut in pieces, and cook thirty minutes before straining.

Corn.—This seems to be one of the most difficult vegetables to can successfully, but with a clear understanding of the process of canning, and the causes of spoilage, it may be canned as easily as any vegetable. The corn shoold be absolutely fresh. In picking, it is important that the corn should be between the milk and dough stage —neither too young nor too old. Remove husks and silk, blanch, cold-dip quickly, cut from cob and pack at once in jar. Add seasoning and boiling water, cover, and put into canner immediately. If working alone, prepare corn for one jar at a time, putting it at once into the canner. To can corn on the cob, follow the same method, but pack whole ears in jars.

Pumpkin and Squash.—Remove skin and seeds, blanch until soft enough to mash, then proceed as for other vegetables, or cut in cubes or sections, and can without mashing.

Pod Vegetables.—This class includes peas, green shell beans of all kinds, string beans, and okra. String or hull according to kind. Cut string beans in inch lengths or leave whole. Blanch in steam if possible.

A cloudy appearance of the liquid in canned peas or shell beans that are keeping well may be due to several cases; to the use of water of high mineral content; to the use of peas that are old; to careless blanching that cracks the skins; or to the use of split or broken ones.

Never can pod vegetables that have stood more than five or six hours; and cool as quickly as possible when removed from the canner.

Special Directions for Fruits

General directions for fruits are the same as for vegetables, except that wth many fruits no blanching and cold dipping is required. Fruits should be fresh, firm, and not overripe. Remove stems, leaves, and imperfect fruit, and wash to remove sand and dust.

Soft Fruits.—Such as sweet cherries, peaches, apricots, plums, raspberries, strawberries, blackberries, blueberries, and similar fruits. With the exception of fruits that are pared, do not blanch. Pick over and hull berries, place in strainer, and rinse by pouring cold water over them. Pack carefully at once in hot jars. Blanch and cold-dip peaches and apricots, pare, cut in halves, remove stones, and pack closely in jars.

(Use thin or medium-thin syrup according to tartness of fruit.)

Sour Fruits.—Sour cherries and plums, cranberries, gooseberries, and currants are included in this class. Blanch cranberries and gooseberries as for other products. A more satisfactory method for sour cherries is to stone them, drain thoroughly through cheese-cloth and reserve juice to can by itself. The cherries are much nicer, and the juice is a delicious drink for hot weather. Combned with apple juice the cherry also makes a delicious jelly. Instead of the usual method, try this for sour or strong-flavored plums: Wash, place in an enamel-lined basin, put in steamer, and steam until about half done. Pack at once in hot jars and sterilize for half the required time. Use the juice which collects in bowl for jelly. For sour fruits use medium-thin or medium-thick syrup as preferred.

Hard Fruits.—This class includes apples, pears, pineapple, and quinces. Blanch and cold-dip quickly, and cut in halves or sections as desired. If blanched after paring, some of the flavor is lost. Pineapple is an exception; pare, remove eyes, and cut in cubes or slices before blanching. Use medium thin or medium thick syrup according to taste.

Syrups for Canning

Syrups for canning are made by boiling sugar and water together until of the desired consistency or "density." A simple formula is three quarts water to two quarts sugar boiled to a thin, medium-thin, medium-thick, or thick syrup.

Thin Syrup.—Boil until sugar is dissolved but syrup is not sticky. (Density 12 to 20 per cent.) Use for peaches, mild apples, or pears to be used for salads.

Medium Thin.—Boil till syrup begins to thicken, and becomes stocky when cooled on finger tip or spoon. (Density 20 to 40 per cent.) Suitable for blackberries, currants, blueberries, etc.

Medium Thick.—Boil till syrup rolls or piles up over edge of spoon when it is poured out. (Density 40 to 50 per cent. Use for strawberries, red raspberries, pineapple, and any sour fruit.

Thick.—Boil till so thick that syrup pours from a spoon with difficulty, but remains smooth. This is used only for preserves.

GENERAL DIRECTIONS FOR COLD-PACK METHOD

1. Use sound vegetables and fruits. Can peas, beans, corn, string beans, and all kinds of greens on the day they are picked. Do not attempt more at a time than can be done properly.
2. Put canner with required amount of water over fire to heat. Put the jars into the canner while the water is cold, or into a large pan of cold water, so that they will be hot when the vegetables are ready. Fill teakettle or large kettle with water to heat for blanching and filling jars.
3. Wash, clean, and prepare for blanching. The time required for blanching is given in the table below. To blanch, place the prepared product in cheese-cloth or in a wire basket and put in steamer, or boiling water to cover for the reqired time. Blanching loosen the skin so as to remove it with little loss of pulp; removes strong or bitter flavors, and objectionable acids; and reduces the bulk so that there shall be no shrinkage in the jars.

   Always blanch cauliflower, cabbage, and all kinds of greens in steam instead of boiling water, in order to prevent the loss of vegetable and volatile oils.
4. Remove from boiling water and plunge two or three times into a large pail of cold water, to harden the pulp, and check the flow of coloring matter. Do not let stand in cold water.
5. Prepare for packing by removing the skins and cores, and cutting in cubes,. slices, or sections when not to be canned whole.
6. Pack closely in hot jars to within half an inch of the top. With vegetables add one teaspoon salt to a quart. For corn, peas, and other vegetables containing sugar it is an improvement to add two or three teaspoons sugar. Fill jars with boiling water. With fruit add boiling syrup.
7. Adjust rubbers and tops, and snap the top bail, leaving the lower bail loose during sterilization. If Mason tops are used, screw as tightly as can be done with thumb and little finger. If absolutely tight there is danger of breakage.
8. **Sterilization.**—When filled put jar at once into canner; the few minutes extra time for those put in first will do no harm. When all the jars are in, cover canner tightly and begin to count processing time when the water boils vigorously. Be sure that the water covers the containers to the depth of one or more inches; otherwise liquid will enter the canner from the jars. Keep water boiling hard all the time. (See time table.)

   Sterilization is sometimes called processing. It is the most important part of the work, for by long boiling all bacteria, spores, and other germs are destroyed. It is well not to cook longer than the required time, as it causes shrinkage, and softens the product overmuch.
9. Remove jars from canner, seal, and turn unside down to test for leakage. If there is a leak from an imperfect rubber, replace with a good one, and return to canner for five or ten minutes. Place jars upside down on a cloth until cold. Cool quickly as possible, but keep out of a draft to prevent breakage. Do not cover.
10. Store in a cool, dry and dark place. If exposed to light, wrap or cover with paper, as direct light often affects the color, sometimes bleaching the product, sometimes darkening it. Continued dampness decomposes rubbers, thus causing spoilage of product.

Time Table for Vegetables and Fruits

Products	Blanch or Scald	Sterilize in Hot-Water Bath
String Beans	5-10	120
Green peppers	5-10	120
Cabbage	5-10	120
Brussels sprouts	5-10	120
Cauliflower	3- 5	60
Greens, all kinds	15	120
Green shell beans	5-10	180
Peas	5-10	180
Sweet corn	5-10	180
Pumpkin and squash		
Mashed	30	90
Cubes	10	90
Kohl-rabi	5-10	90
Carrots	5-10	90
Parsnips	5-10	90
Beets	5-10	90
Turnips	5-10	90
Sweet potatoes	5-10	90

Products	Blanch or Scald	Sterilize in Hot-Water Bath
Tomatoes	1-2	22
Strawberries		16
Blackberries		16
Blueberries		16
Sweet cherries		16
Mild plums		16
Peaches	½	16
Apricots	½	16
Grapes		16
Currants	1	16
Gooseberries		16
Sour cherries, plums	1	16
Apples	1-2	20
Pears	1-2	20
Quinces	1-2	30
Pineapple	5	30

The time requirements given above are based upon altitude of 500 feet above sea level. For every thousand feet increase in altitude, add 10 per cent to the time given.

HORTICULTURE.

DISEASES OF VEGETABLE CHILDHOOD

When your seed-bed was made, plant food was doubtless incorproated in the soil. But little plants, like growing children who need slices of bread and butter between meals, demand something more than the manure you forked into the ground. You can supply that need by a tonic application of one or more fertilizers. Bone emeal, nitrate of soda, commercial fertilizers, wood ashes, sulfur and lime—all are tonic in their effeect on vegetable lifee

But in applying them you must act with discrimination, for each has its particular function in aiding plant growth, just as quinine, strychine and belladonna have each their specific use in the curing of disease. Nitrogen plays the most important part in the growth of leaves and succulent stems and therefore is particularly valuable in the production of such crops as cabbages, lettuce, Brussels sprouts, spinach, kale, Swiss chard, endive, celery, sweet corn, and asparagus. Also large amounts of nitrogen are necessary in growing onions.

However, there are many forms of nitrogen, and this fertilizere is valued largely accordinig to its availibility, that is, according to how quickly the plants can get it. Nitrate of soda dissolved in water makes a plant food that is available the minute the water has sunk into the ground. Hence nitrte of soda is the quickest of all the stimulating fertilizers named. Stable manures, dried blood, tankage, bone meal, and other organic matter that supplies nitrogen must rot before the nitrogen content is available to plants. Nitrate of soda is very costly just now, yet for the mony invested it probably gives larger net returns than any other fertilizer.

Use Nitrate of Soda with Care

When your lettuce plants are three inches high, give them a little nitrate of soda and apply more three weeks later. Scatter a pinch of the stuff about each plant and rake it into the soil. A mere pinch is enough, for nitrate of soda is so powerful it will kill the plants if you apply too much. The best way to use it is to dissolve it in water at the rate of an ounce to a gallon, and sprinkle the soil about your plants with the liquid. Even then you will have to be careful, especially if it is a wet season.

Some years ago a friend of ours had some unusually fine young plants that suddenly began to droop. There was no visible cause for the trouble, and the gardener suspected that a cutworm had been at work below the surface of the ground. With his pocket-knife he careefully scraped the earth back from the stems of the plants until he laid bare the roots. There he found the trouble. On the roots were tiny globules of nitrate of soda. He had been watering the plants with a solution of that fertilizer. It was a rainy spring, and the excesisve rainfall had carried the dissolved fertilizer down into the earth much faster than it would ordinarily have gone. The result was the accumulation of the little globules on the roots. Once these were scraped off, the tomato plants regained their vigor.

Bone meal, tankage, manures and other forms of nitrogen may be applied freely about young plants, since they give up their plant food slowly as they rot. You must be careful shrd as they rot. Yet care must be used when applying hen droppings. They are one of our most concentrated manures. The best way to handle hen manure is to pulverize the dry droppings—incidentally hen manure should be kept perfectly dry—and mix them with an equal or even greater bulk of soil. The resulting mixture can be safely worked into the soil about plants, but care must be taken to prevent any of the manure from coming to direct contact with the roots of the plant.

An acquaintance of ours tried hen manure in his garden one summer. Being unacquainted with its properties, he put a quart of pure hen droppings under each of his squash hills. They started out like Jack's bean stalk, being hustled along by the heat generated by the manure. But when the roots grew long enough to reach into the manure, the squash vines turned a sickly yellow and soon died.

The Importance of Potash

Potash is especially important for the root crops, such as radishes, turnips, beets, parsnips and carrots. Potash is particularly good for potatoes. It enters largely into the composition of many other vegetables. Just now potash is practically impossible to obtain. Potash came mainly from Germany, and we have succeeded in producing but little in this country. The liberal use of potash tends to make the soil sour. Sour or acid soil is sweetened again by the use of lime. It happens that wood ashes contain a large percentage of potash and considerable lime. Hence wood ashes will be found useful for most root crops. There is one notable exception however. This is in the case of potatoes. Potatoes thrive best in an acid soil, and neither lime nor wood ashes should be applied to them. At the Virginia Truck Experiment Station lime was applied to various crops to observe the effect. The cabbage crop was greatly increased; in fact the yield of all crops except peas and beans was markedly increased. It will be well for the home gardener to bear these facts in mind, for lime can stil lbe obtained in any quantity desired.

Garden soils are very likely to be deficient in phosphoric acid, and without this necessary ingredient plant growth is limited. Phosphoric acid is obtainable in various forms of fertilizers that are popularly termed "phosphate." The most economical and most effective way to apply any of these plant stimulants is to wait until your plants are well started, like the lettuce plants, and then apply the fertilizer either along the rows or close about each individual plant in the row, raking the material into the soil after scattering it. Thus applied, these vege table tonics will almost certainly result in strong, sturdy litplants.

Garden Children Have Their Troubles

But no matter how well and vigorous children are, they are stil liable to certain ailments, and children of the garden are no exception. Bugs and blight, including mildew, are the enemies that call for the use of the spray pump. For a small garden one can get along with a tiny hand pump that costs fifty or seventy-five cents and hold perhaps a quart of liquid. For a good sized family plot some kind of portable sprayer that holds three or four gallons will be found most suitable. These can be obtained for seven or eight dollars and will last indefinitely. If you buy one, by all means purchase one with a brass container, even though it does cost a little more. The galvanized containers will sooner or later corrode; the brass is not affected by spraying materials. These pumps are suspended from the shoulder by a strap. So supported and tucked under the left arm, they are easily handled, even though they contain many pounds of liquid. A single pumping charges them with compressed air which will force out the liquid for perhaps ten minutes. Thus one can walk through the rows of plants, applying the spray mixture as one goes. With this rapid system an entire garden can b esprayed in a short time.

Blight and mildew cause plants to turn sickly-looking and shrivel up. Potatoes are susceptible to blight, particularly the early varieties. Blight and mildew are caused by spores that multiply with incredible rapidity when wet. Hence rainy seasons are particularly bad for blight and mildew. Plants susceptible to these diseases should be sprayed when they are two or three weeks old, and thereafter spray material should be applied to them every ten days or two weeks. It is particularly advisable to spray before a rain rather than after a rain. When wet plants are handled, there is danger of spreading disease germs. Hence beans, peas, melons, cucumbers and other plants subject to mildew or blight should never be treated when they are wet.

Melons, squashes and cucumbers form a little trinity that suffer similarly from bugs and disease, hence require similar handling. For blight and mildew spray them when the vines begin to spread. Spray potatoes for blight, applying the liquid to both the upper and under sides of the foilage. Peas are also subject to mildew. Brown rot affects plums and cherriese and peaches. Blight and rust affect celery. Beans are subject t oboth blight and pod spot. Mildew also attacks the onion. For all these diseases spray with Bordeaux mixture.

Bugs Are Dangerous Enemies

The bugs that attack garden children are of two sorts; those that chew the leaves and stems, and those that suck the juices of the plants. Each sort requires a distinct treatment. Chewing insects must be poisoned. Sucking insects must be killed by some spray that will destroy them by contact, as carbolic acid will destroy

Massey-Harris

Reliability its Great Feature

The great feature of the Massey-Harris Mower is that it can be depended on to go through Haying without a hitch. It matters little how many other features a Mower has if it gives out, for any reason, during the Haying Harvest. The Massey-Harris Mower removes the fear and worry of having trouble with your Mower at that time. So in choosing a Mower get one you can depend on—the Massey-Harris.

The features that make the Massey-Harris thoroughly reliable are its strong, sturdy construction, giving durability, easy-running with the absence of side-draft altogether. It is easy to handle, a new and improved Foot Lift enabling the operator to raise the Bar easily and there is no sagging at the outer end. It cuts clean and handles all kinds of crops.

Cuts the last Swath as certainly as the First.

Eureka POTATO DIGGER

Saves Extra Help

Pay for your Eureka Potato Digger with extra money earned by getting the whole crop early and selling while prices are high. Get the crop before it freezes in, without extra help.

The Eureka works in ground and conditions where other diggers fail. Because Eureka elevator and duplex shaker provide more separation; its big wheels and main gears give big power; its high clearance over shovels prevents weeds and vines bunching. Has vine-turner attachment. Special construction prevents frequent breakage. Growers report digging 150 and more acres without repairs.

Adapted for use with tractors; with or without engine attachment. 6 and 7 ft. sizes; several styles.

In stock near you. Write for catalog.

human babies. Paris green and arsenate of lead are the favorite poisons. The powdered forms of all spraying materials are preferable to the paste forms. Mix the proper poison with your Bordeaux and so kill two birds with one stone—get both blight and potato bugs. Potatoes, cucumbers, squashes, melons and other plants that are being eaten should be sprayed with a poison. where plants are attacked by sucking insects, like scales or aphids, some spray like a tobacco concoction, or whale-oil soap, or kerosene emuls on must be used.

In an article of this length it is not possible to give in detail all the directions necessary for spraying. Every gardener should write his agricultural station or to the Department of Agricultre for free booklets on spraying and on insect and fungous enemies of vegetables. These pamphlets will acquaint one with the habits of these enemies and tell specifically how to combat them. Every gardener should familairize himself with spraying practice. In recent years there has been a marked increase in some of these plant enemies.

It is not worth while to go to the expense of buying seeds and to the labor of planting them, if in the end the gardener is to lose the fruits of his labor through lack of protection for the growing plants. And to a certain extent that is exactly what must happen in every garden unless the gardener arms himself for conflict with the marauders. Just as the gardener has his spade and hoe and fork and rake and tape line and sprinkding ca nand wheel cultivator, so he should have his spray machine and his little sheelf of spray materials. They are an essential part of modern gardening. tI is only by scientific methods that the gardener can reduce the death rate of his garden children.

THE CORE OF THE FRUIT INDUSTRY

Every apple grower knows that the core has five sections, each bearing a well-matured plump seed when the fruit is ripe. This core is the centre of reproduction. The surrouding fruit that we value so highly is but a camouflage, some say, to assist animals in distributing the innermost seeds when the ripened fruit has .fallen Now the orcharding industry has a core essentially like that of the fruit which it markets This core has to do with the essentials to the production of best crops It, like the apple core, consists of five distinct parts—to wit, first, proper variety of fruit; second, proper mechanical condition of orchard soils; third, the effective control of insects and diseases; fourth, proper supply of orchard plant food; fifth, proer marketing of the produce.

Granted that each of these essentials is given its merited attention, the growth, blossoming and fruition of a satisfactory fruit industry is assured. Space will not permit our discussing each of these essentially important factors but we shall confine our remarks to that factor which has to do with the early feeding of the crop, which function latest orchard investigation has shown absolutely determines the strength of "set" of fruit and the development of the fruit itself.

The long-time orchardist will possibly be inclined ta ask why the orchard should not need feeding. Its trees send out their extensive root systems far and deep into well prepared soils. Proper pruning prevents excessive drafts upon the root system of the tree, while care to other essential factors, with the exception of plantfood, keeps the tree in a comparatively healthy condition. But this is the very point. . A man may be healthy and may not overtax his strength, but if he does not have a better balanced supply of plantfood than he can get from hunting and fishing under normal conditions, he is unable to keep up his maximum energies. Just so with the orchard. The growing tree, although it seems a much stronger plant than the flowering plant of the home or the tomato of the garden, is bulit up of cels just the same as are the tender plants. These cells are equipped esentially the same as the cells of other crops, and require like nourishment if they are to thrive and reproduce both in foilage and fruit.

Starved Orchards

A notable instance of orchard starvation is reported by the Ohio Experiment Station. This station some years ago inaugurated a study of the extensive orchards of the Ohio Valley, which orchards had ceased to produce a satisfactory return. The fruit trees blossomed in profusion. Their foilage was beautiful to behold, but when it came to setting of fruit there was not sufficient strength to maintain the draft upon the soil. The result was disappointment and loss instead of a thriving orcharding industry. The Ohio Experiment Station found that the shortcoming of this section was lack of plant food. In view of this fact it inaugurated an extensive fertilizer demonstration, which, in the course of a litle over seven years, brought back many of the orchards, reviving them, and in fact developing them far beyond the former important orcharding industry of that territory. Two systems of orchard practice were investigated, the sod and the cultivated orchard. In both instances, what were considered suitable fertilizers were applied in sufficient quantity to materially nourish the apple trees. In fact in 1914 the rows of Ben Davis apple trees shown on the front cover of this issue of the Canadian Horticulturist, containing 12 trees each, produced 49 barrels of large marketable apples, where fertilizer was applied, but only 20 barrels of inferior fruit where nothing was added. In 1915 these same rows yielded as follows: Fertilized, 46 barrels; unfertilized, 9 barrels.

Maintaining Humus

There were two things to which the orchardists paid special attention. One was the upkeep of humus, which was accomplished by the addition of one bale of straw around each tree annually and a proper supply of plantfood, which the station supplied in 12½ lbs. of mixture of fertilizer made up of 5 lbs. of nitrate of soda, 5 lbs. acid phosphate, 2½ lbs. of potash. This same uqantity of plantfood is supplied by 12½ lbs. per tree of a fertilizer analysing 6 per cent, ammonia, 6.4 per cent. phosphoric acid and 10 per cent. potash. Quickly available ammonia caused rapid tree growth, along with vigorous twig and bud production. Phosphoric acid hastened ripening and helped the setting of fruit, while potash assisted in laying down starch and gave general vigor to the tree. The Ohio Station, in speaking of the effects of fertilizing this orchard, says: "The first noticeable effects of fertilization in these starving orchards were discovered within two weeks from the date of application where the quickly soluble promptly available nitrate of soda had been applied around the trees, either alone or in mixture with other forms of plantfood. Dark green circles or "belts" around the trees caused by the thin mixed growth of weeds and grasses, taking on a much deeper, richer shade of color were distinctly outlined. . . . These changes were remarkably noticeable within a month, as the fertilized rows of plants were compared with those left unfertilized."

Orchard fertilization has also been extensivly examined by Pennsylvania Agricultural Experiment Station, who have reported on their tests in bulletin No. 153 of that Station. The Pennsylvania orchardists made tests of the application of ammonia and phosphoric acid and of complete fertilizers. When applied to old orchards they found that in one orchard the increase per acre per annum from the addition of nitrogen and acid phosphate was 265 bushels per acre, while that on another orchard was approximately 309 bushels per acre. When plantfood was applied to young growing orchards, the following results were obtained:

Gain Over Normal Years

Nome of Orchard	Nit. & Phos. Acid	Complete Fertilizer
Strode	45.9 bus. acre	46.4 bus. acre
Tyson	55.1 bus. acre	89.9 bus. acre
Wertz	15.9 bus. acre	59.0 bus. acre
Mynard	17.1 bus. acre	69.7 bus. acre

This station. too, has been able to demonstrate that trees can be profitably fed like tender plants and growing animals. The station says: "The crops on these plots (Brown orchard) in 1917 were 25.3 bus, per acre on the unfertilized trees, and 662.6 bus. on those reeceiving fertilizers.

The Value of Tests

Tests and findings in nearby or distant locations are of precious little use unless applied to our local conditions . A great deal is being said about soil characteristac and their influence on crop production, and we do not for a minute wish to minimize the importance of the soil type; nevertheless, the soil side of the question is but half of the problem. Apple trees use the same essential plantfoods whether they are grown in the eastern counties of this province, or elsewhere. This is a point which should constantly be kept in mind by business orchardists. Moreover, it should be kept in mind that the soil analysis of the sections where the Ohio and Pennsylvania experiments were carried on, do not differ materially from the analyses of the soil in many of the orcharding sections of this province. The only material difference is that in Ohia and Pennsylvania the apple crops have a much longer growing season in which to mature, which fact in itself only emphasizes the greater need of paying attention to the fertility side of orchard management in Canada.

DAIRYING

FITTING COWS FOR LACTATION. A GOOD RATION AN EXERCISE ARE ESSENTIAL

All animals, when in proper environment and under normal conditions, naturally take on flesh during pregnancy, the reserve being used in milk production when the young is born. As we expect a dairy cow to give much more milk than her calf requires, it is only reasonable that she should be in extra good condition of flesh at calving time. A further consideration is the procuring of strong, well-nourished calves which cannot be expected from poorly-nourished cows. Grain fed during the dry period has been found to give greater returns than the same amount of grain fed after calving, these returns being in the form of a more vigorous calf and increased milk production. To have the cows in proper condition of flesh, one of the first requisites is to give them sufficient rest between lactation periods . The cow that is milked up to within two or three weeks of calving may pile up quite a record for that year, but she will surely fall off in the next lactation period Each cow should have from six to eight weeks of a rest period.

The feeding of the cow during this period will depend upon her condition when dried off. If she is in good condition of flesh then very little more than a maintenance ration is necessary, but the feeder should watch that she does not lose her thrifty condition. If she has become thin and run down then a liberal ration should be allowed. The character of the ration need not differ materially from that fed to the milch cows. Pasture, supplemented by silage or soiling crops in summer, and roots or silage and legume hay in winter should be sufficient for the cow in good condition. Those in poorer condition should receive grain in addition up to six or seven pounds per day if necessary. It is important at all times that dairy cows receive a laxative ration but particularly so just at calving time. To this end, the grain ration should consist of such laxative feeds as wheat bran and oil cake together with either ground oats, barley or corn, preferably the former, in equal parts. For every 100 pounds of the above grain mixture there should be added 1 pound of ground rock phosphate, charcoal and common salt. The salt is a necesity in the ration while the other ingredients act as a tonic. Cows not receiving the grain should be fed some of this tonic mixture separately, or the last day or two before calving the regular ration should be replaced by bran alone which should be fed up to calving time and for a few days afterwards.

To ensure the best results from the above method of fitting the cow for her lactation period she should be allowed plenty of exercise. Running with the milch cows in summer and being turned out in the barnyard for an hour or two daily in winter will meet requirements in this regard. This exercise will be found to do away with many of the calving and udder troubles experienced with cows high-fed on heeat-producing foods just previous to calving.

ADVERTISING IN BEHALF OF IMITATION BUTTER

One of the aproved methods of "putting anything across" in Canada is to circulate through the press of the country carefully designed articles without any indication of being advertisements, which are calculated to spread a false impression of the question, and bolster it uy from beneath without attracting the opposition of those who are opposed, until the damage is done and a great "public opinion" is developed which can not be easily shaken or moved.

A fair illustration of this principle is found in the oase af the 1911 federal election, when the tariff issue was obscured by the patriotism cry. Today it comes up in another form, in the campaign being waged from behind the scenes to make the people of Canada favorable to a continuation of the market here for imitation but-

There's Nothing Like It.
THE FAMOUS
RELIABLE CHURN

If you are tired of "SHAKING" the butter from your cream, investigate the "Reliable" Churn.

It "CHURNS" for you just as effectively as did mother's old fashioned "Dash." Gets "all of the butter from the cream," and many times more easy.

Its clever mechanism gives that efficient perpendicular stroke, but with a high-geared rotary drive, and it is easier to keep clean, too, just lift out the smooth, white, [illegible] glazed jar and rinse.

You can get a book which illustrates every part, gives you full information of hand drive (which can be operated by a child of six) belt drive and electric drive Reliable Churns.

ter, which can scarcely be called oleomargarine, because no "oleo" enters into the composition of the latest margerine, which is composed of vegetable oils entirely.

(Incidentall, this is one of the ways in which the industry works. It got a footing on the ground floor of cheapness, but Canada's animal husbandry was protected against the vegetable product, by its explicit exclusion. Later the packers were able to have this restriction quietly withdrawn, without attracting public attention in any way.)

It has been found that law-breaking is continually associated with the oleomargerine industry, because its very life depends upon the fraud that it is as good as butter, and may sell as such to the unwary. This has been the history of the industry in the United States, in spite of repeated attempts to kep the industry in hand.

The intent to defraud comes to light again when one buys any oleomargarine in Canada. Coloring matter in it is explicitly forbidden by our Canadian laws, but every seller of oleomargarine will tell his customer that he can go to the drug store and buy the coloring matter, so that it can be passed on as butter.

Fraud is also evident in the number of reading notices which are cropping up in the papers of Canada, in regard to the general advisability of having the spurious butter in the Dominion. Spacious arguments are therein advanced in its favor, and everything possible is done to remove the prejudice. But not all newspapers are willing to pass this fraud on as their own opinions, but insist on labelling the articles as advertisements, nominally, at least. This was done by the Calagry Albertan in a recent issue, when at the close of an article a half column long, it placed the letters, ',Advt." Not everybody would recognize this calabistic sign as indicating the fact that the news item was paid for by some one, but it goes as a salve t othe printer's conscience, and is vastly better than the practice of others of allowing it to go out as the editorial and unbiassed opinion of the paper itself, and not, ts in fact, a part of the wealthy packers of Canada and the United States.

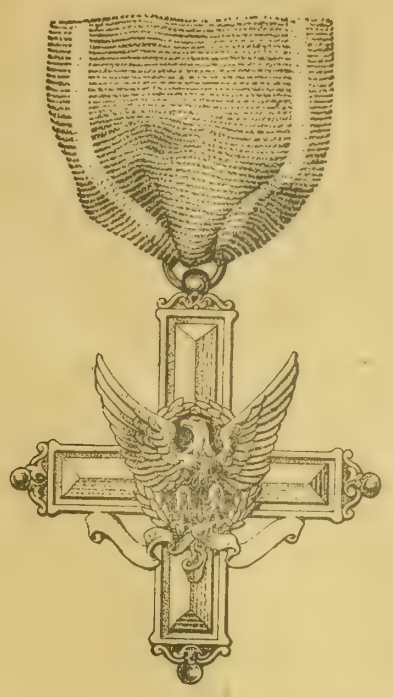
The news item in question blandly closes with the peroration: "If oleomargarine is made so good that its competition is feared by the butter industry, if it is clean, wholesome and nutritious, and is sold on its merits at reasonable prices, it clearly has a high and legitimate place among our standard food products.—Advt."

But when the product which it lauds is recognized as a fraudulent imitation of butter, of lacking in the growth element necessary for children, and flourishing in fraud and illegality, its legitimacy is obscured.

CANADA'S 50-lb. COW

Rolo Mercena Dekol, owned by J. B. Hanmer. Norwich, Ont., has recently completed a seven-day test, which makes her the first fifty pound cow in Canada, the second fifty pound cow in the world, and, which will give even more satisfaction to Canadian Holstein breeders, she exceeded the 50-lb. mark by a sufficient margin to make her the world's greatest seven day producer of butter fat. The following, we believe, are all world's records: 51.92 lbs. of butter in seven days; 200 lbs. butter in 30 days; eight pounds buteer in one day. In her best day she gave 125 lbs. of milk. It is especially worthy of note that Rolo Mercent DeKol was in thin condition at time of calving and was being milked only twice a day when the supervisor arrived. The record is, therefore, in no sense an artificial one, as was the case with the former title holder who had been dry a long time before the test started, was loaded with fat and went through her test in a thoroughly equipped test barn.

The new record gives to Canada the disctinction of owning both the butter and milk champions of the breed in official tests from seven to thirty days the milk records already being held by Mayo Echo Sylvia. This is a record of which Canadian Holstein men may well be proud.



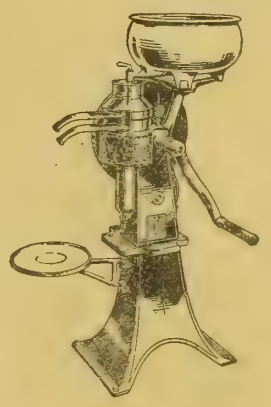
DE LAVAL

"The Distinguished Service" CREAM SEPARATOR

There is service built into every part of a De Laval. Forty years of leadership in cream separator construction have made it the unquestioned leader in close skimming, light running, easy cleaning and durability.

The De Laval is sold through local agents who are well informed with regard to the machine and Company's policy. These agents localize the Company's service. They carry repair parts in stock and are trained to give intelligent advice and prompt help, in order to insure complete separator satisfaction and continuity of service.

There is a De Laval agent in every dairy community throughout the world—a constant reminder of the fact that when you buy a De Laval, the Company feels that its obligation to you has just started.



It is because of these facts that the De Laval has been justly called

"The Distinguished Service Separator."

LIVE STOCK.

NO BETTER TEST OF REAL STOCKMAN THAN THE MANNER HE CARES FOR YOUNG ANIMALS

It has been truly said of the newly weaned animal that upon the care and management it receives during the few months after it has been deprived of its mother's milk and summer pasture, both of which are usually taken from it at the same time, depends to a great extent its future usefulness. If the change made is too violent and the treatment given without very much consideration, a serious setback is bound to occur, for the young animal is passing through one of the most critical periods of its life. Neglect at this particular time is largely responsible for the great loss suffered by the live stock industry. Discussing this subject, Prof. B. E. Carmichael, of the Ohio Experiment Station, says:—

"What are the needs of the rapidly growing yongster that is deprived of the abundant and efficient supply of milk that nature has provided through its dam? The fact that the young animal is growing rapidly should supply more than a hint that there is need for a generous amount of feed, since rapid growth or rapid production of anything by farm animals, is impossble without an abundant supply of feed. If there is any one attempted economy which is generally poorly advised it is the one which limits the food supply for growing animals to so low a pont that it is not possible for them to grow normally. While it is not necessary for the breeding or work animal to carry through its life nor even through the period following weaning, the large surplus of fat with which the sucker is often provided, yet there should be maintained a reserve supply of fat that will prevent the animal from becoming much emaciated by hardships which are sometimes encouraged in the form of accident or disease, or attacks of parasites, internal or external.

Feeder's First Lesson

The well nourished calf or foal, or any other youngster about the barn, gets abundant supply of nutriment and gets it at frequent intervals. This is the first lesson to the caretaker who is to look after the welfare of the farm weanlings. Never more frequent feeding of the newly-weaned animal than is given to the older ones is, as a general thing desirable. Whatever the kind of animal that is being weaned, care should be exercised to keep it doing well and it is well worth while for the owner to watch it closely and give the little attentions here and there as needed. While it is not literary true that "the eye of the master fattens his cattle," yet the owner who does not keep an eye on the stock during critical times is likely to have stock which is far from prosperous.

Careful attention should be given to the kind of feed that is supplied the youngster that is newly weaned. Growth should be promoted by the use of feeds which carry an abundance of protein and mineral matter without which normal growth is not possible. Such nutriment is provided by various kinds of green forage, skimmilk, tankage or meatmeal, linseed meal and leguminous hay, and these or similar feeds should be used in connection with the farm-grown grains that are most abundantly available, if the best results are to be secured.

"How often it is found that the youngster comes out of the winter conditions weighing less than it did when it left its mother six months before. The loss of weight that so often accompanies the weaning process may be avoided, or at least reduced materially, if the young animal is taught to eat grain before it is weaned. If not accustomed to grain before being weaned, care should be exercised in introducing grain into the diet of the young animal. Overfeeding is to be avoided, even though generous feeding is desirable as soon as the animal has become accustomed to the new ration. Many good young animals are given a setback by the combination of neglect and laik of suitable feed which makes ti difficult to get them into desirable condition before the trying winter months are well over.

A Dry Bed and Dry Back

"Shelter from extremes of temperature and from storms, especially the storms which combine cold, wind and rain, should be provided. No animal should be subjected to exposure of this kind, and the weanling is especially susceptible to its damaging influence, particularly if not well fed and in good condition. 'A dry bed and a dry back' are needed even during te moderately cold weather of fall and early winter. Providing them will save much feed and may avoid serious loss from diseases that result from undue exposure.

"Every unthrifty weanling causes an important economic loss. Whatever the animal, if it is worth developing it should be so handled that it will be able to perform well the service for which it is intended. Both humane and business consideration make it imperative that the weaning animal be given adequate feed, shelter and care. It is probable that there is no better test of the real stockman than the manner in which he cares for the young animals in his herds and flocks. No breeder or feeder who neglects the animals in his care is doing his full duty, and the man who fails properly to develop the animals he raises is doing much to counteract the good work that has been done in bringing farm animals to a high standard of utility. The whole matter is one in which thoughtful foresight, instead of heavy expenses, counts.

Starvation Breeds Parasites

"There is a particular need for guarding the young animal from the damage that results from heavy infestation of parasites. Though there is but little doubt that a large amount of the damage credited to parasites is due to partial starvation, yet more than good feeding is often needed. There is no easy and effective way to avoid all of the losses from parasites. It is advisable to give the young animals access to pastures and quarters that have not been used by animals that are infetsed by the kinds of parasites that are likely to attack the young ones; useful though this precaution is, it alone will not always suffice, and it is frequently necessary to give the animals definite treatment in order to free them from the parasites that they harbor in sipte of the careful precautions that it has been undertaken to follow. Seldom indeed does a single treatment rid an animal of all the pests for which it is administered. Enormous losses may be at least pratly avoided by giving careful and persistent attention to the holding in check of the parasitic enemies that are so harmful when harbored in large numbers by young animals."

TEASING BULLS AND STALLIONS

Many good bulls and horses are spoiled every year by thoughtless children and grown-ups. An animal once spoiled by careless handling or tinkering, is hard to be broken of it, so strong is habit, and usually is sold at a reduced price because "his conditions" are no good.

Most horses are ruined while they are still colts. Running from them while they are playing is bad policy

Standard Stock Feed For Sale

A Valuable Feed for all Classes of Stock

THREE thousand tons of this stock feed is still available for distribution, and farmers should order now before supply is exhausted.

This Standard Stock Feed which is in store at Ft. William, consists of recleaned elevator screenings.

By actual feeding tests at various Dominion Experimental Farms it has been proved excellent for dairy cattle, while for finishing pigs it is equal to barley. For fattening lambs it gives very satisfactory results, as well as for fattening steers. It also makes an excellent poultry feed. It contains 14% Protein, 5% Fat and 8% Fibre.

Over fourteen thousand tons of Standard Stock Feed have been sold and distributed by the Feed Division, and have given excellent results. Order a car load now as the quantity is limited. Be sure to state whether you require it *ground* or *unground*.

UNGROUND
In Bulk, per Ton
$26
f.o.b. Fort William

Payable on Arrival

Orders should be sent direct to Feed Division, Live Stock Branch, Ottawa, for straight car lots only—(about 30 tons to a car.) Join with your neighbor: and order a car on shares. Terms—Sight draft with bill of lading attached, payable on arrival of car. Orders filled strictly in turn as received.

GROUND
Per Ton, in Bags of 100 lbs.
$34
f.o.b. Fort William

Pamphlet No. 18 giving full particulars sent on request with samples of the feed.

W. A. DRYDEN, *President*, Brooklin, Ont.
G. E. DAY, *Secretary*, Box 285, Guelph, Ont.

Shorthorns

and may result in making a very vicious animal. Fences should be kept up around young stock. When driving load light, rest often, and see that the collars fit perfectly.

Bulls that have been teased and become vicious are a source of danger as well as annoyance about the place. Careful handling will keep them from becoming dangerous, but many a man who carelessly handles the bull has to pay the price for it with his own life, in doctor bills, or lawsuits.

Children should never be allowed to throw sticks and rocks at the young bull. Boys should be kept from worrying him, by driving him hither and thither in the fild.

It is needess to say at all times to keep a high, strong woven wire fence around his pasture. Have the posts of good sound timber set at least two or two and a half feet in the ground.

Don't let the young fellow learn of his enormous strength. Use a good bull nose leader to handle him by at all times. Never use just a common halter. Breaking away a few times will make his unruly.

Never go into the pasture unprepared to defend yourself from his attacks. You do not know when he will take a vicious notion. Do not use a dog unless absolutely imperative, then use one that will catch and hold until you say to let loose.

THE HIGH PRICE OF OIL CAKE

The high price of Oil Cake and Cotton Seed Meal can be largely offset by the regular use of Herbageum. It enables the feeder to use more roughage and reduce the ration of expensive meals while maintaining his animals in prime condition. Cornstalks, coarse hay and straw contain a large amount of food that animals are unable to fully asimilate and they can only be given in limited quantities. Regular use of Herbageum overcomes this difficulty and much larger quantity of roughage can be profitably used and the animals maintained in prime condition with their maximum production of flesh, milk, butter or wool.

Herbageum given regularly twice daily as directed requires but 1-lb. per month for a horse, cow or hog and the cost is only 25c. per lb., which is less than one cent a day per animal.

As good calves can be raised on skim or separated milk seasoned with Herbageum as on new whole milk without it, and the pork will be firmer than flaxseed or oil cake for calves. Try it. Pigs will thrive on fresh whey and Herbageum. As good weights can be asured with hogs at six months with Herbageum as at eight months without it, and the pork wil be firmer and sweeter and the lard of a better quality.

Herbageum is without equal for poultry and when given regularly to sheep there is no trouble with ticks and sheep dips are not required, the wool clip is heavier and in every way superior.

Herbageum has been in regular use during over thirty years and all we claim can be substantiated by thousands who use it.

The Beaver Mfg. Co., Sole Manufacturers. Galt, Canada.

SHORTHORNS FOR GRADE BREEDING

After all it is the man who is breeding grade cattle and raising animals for the butcher, who decidse which breed shall flourish and which shall be discarded. It is here that the Shorthorn makes a particularly strong bid for favor, and is accorded general recognition. The meanest scrub cow is mated with a good Shorthorn bull, will produce progeny that will grow to good size and make a reasonably good feeder. For example, the second prize grade yearling steer at the 1918 Ontario Provincial Winter Fair, who was beaten in his class only by the grand champion of the show, was out of a mean little Shorthorn bull. One has only to study the grade herds of this or any other country to become convinced of the merits of the Shorthorn. Those big, roomy, square-ended grade ecows, many of them deep milkers, just the kind you would select from which to breed profitable steeers, are difficult to find outside of our grade Shorthorn herds.—G. E. Day, Sec. Dominion Shorthorn Breeders' Assoc., Guelph.

THE AGE OF CATTLE

The art of telling the age of cattle is best learned by carefully examining the teeth of numbers of calves and cattle of known age. Experience then makes perfect in "reading" the teeth. The calf has eight small white milk teeth in the front of the lower jaw. Cattle have no teeth (incisors) in the front of the upper jaw. At from 19 months to two years, the central pair of milk incisors is replaced by permanent incisors, which are much larger and broader than the first teeth. The next pair comes in at from 2¼ to 2 years 9 months. Between 3 and 3½ years, the third pair comes in and the fourth pair at 3 years 9 months to 4 years when the mouth is said to be full. Precocious, heavily fed or pampered show cattle may have their permanent incisors come in a little earlier than we have stated here, whilee stunted cattle have a somewhat later eruption of teeth. Afte four years the pincers gradually become more and more worn until at 12 to 15 years, the broad part is gone and the small necks of the teeth apper as rounded knobs in the gums.

BRITISH FRIESIAN SOCIETY

The report of the annual meeting of the British Friesian Society shows that it now has a membership of 833, and that its assets now equal nearly sixty thousand dollars. The president stated that the average price at which 931 lots sold in 1918 was seven hundred dollars.

At the meeting a resolution to permit the registry of grade cows of Friesian type and superior merit was defeated. Another resolution was offered providing that no bull shall be eligible to registry unless "out of a cow that shall have given at least 10,000 lbs. of milk in a year, or out ol a first calf heifer that shall have given at least 8,000 lbs.milk— all yileds to be certified by some milk recording society approved by the British Friesian Society." This resolution was referred to the Board of Directors for further consideration.

PRICES FOR WOOL

There has been much speculation, not only in Canada but throughout the whole sheep breeding world, in respect to the price which will be paid for the farmers' wool clip this year. It was currently reported during the early part of the winter that prices might drop as low as 40c and 50c. A little clue to the prices that seem likely to be received may be taken from the report just received from the headquarters of the Canadian Co-operative Wool Growers Limited, which company markets the wool for the Co-operative Sheep Associations in Nova Scotia and other parts of Canada, who have just sold two carloads of Maritime wool at 73c. f. o. b.

This will be very graifying news to the sheep breeders of Nova Scotia and should have a stimulating effect on sheep breeding in the Province and should also put a premium upon the farmers taking the best possible care of their wool and thoroughly posting themselves on the prevailing market prices.

Good drying winds and plenty of sunshine are ideal for hay making.

To be sure some farmers do use poor, out of date farm implements, but instead of saving them money it costs them money.

Dependability

ALPHA Trade Mark

THE KEYNOTE of the ALPHA Engine is dependability. It *runs* when you want it to, day after day, and you never need to worry about it. Its simple, sturdy construction makes it dependable.

The ALPHA power rating is *dependable*; if it is a 1½ Horse Power it will deliver *at least* one-and-a-half horse power; if it is a 28 Horse Power you can bank on getting more than 28—never less.

The De Laval Company is *dependable* — the largest manufacturers of dairy supplies in Canada.

If you don't know who handles the ALPHA in your vicinity, write nearest sales headquarters for his name.

THE HORSE

DISEASES AND DEFECTS IN EYE OF HORSE THAT LESSSEN HIS REAL VALUE

The eye of a horse is more naturally disposed to disease than that of any other farm animal, yet few horse owners or cartakers are aware of this fact . Not only is the horse very liable to have eye diseases, but he is often —more often than is supposed—afflicted with defective sight, which in it. self is more dangerous than total blindness . A blind horse will resign himself to the guidance of his driver, but against the misconception of a horse that only partially sees the surrounding objects there is practically no defence. Many horses are born with defective visions and heredity plays an inmportant part in its appearance, a fact which all horse breeders should consider. The maladies of this organ, though few in number, are frequent in their appearance, and are also very hard to control.

Common Inflammation

There are two forms of inflammation to which the eye of the horse is liable, viz., the common variety that is easily controlled, and the specific that is generally fatal to the eyesight. Common inflammation is generally sudden in its attack; the lids will be found swollen, the eye partially closed, with some weeping. It may be caused by a catarrh or cold, a blow or the presence of a hay seed or similar substance. The muscles of the eye of a horse are so adjusted that it is almost impossible to remove any foreign matter by an operation, as the horse can turn the eye completely round in the socket, thus preventing the removal of the irritating substance. In this case the best thing to do is to apply a cooling lotion made up of half an ounce of laudanum to a pint of water, when the inflammation will gradually subside. Should the inflammation or the injury be so severe that it has involved the inner structures of the eye, great advantage will be derived from smearing the eyebrows and outside of the eyelids with extract of belladonna, one ounce, mixed with half an ounce of honey.

Ophthalmia or Monnblindness

If the eye continues inflamed for three or four days, and begins to get a clouded appearance, then a more obstinate form of inflammation has commenced, and one that wilyl maintain its ground in spite of all efforts to combat it. For three or four weeks the inflammation will continue, or if it appears to yield on one day it will return with redoubled violence on the next. At length, and often unconnected with any means used to ally the disease, the eye begins to bear the light, the redness on the membrane of the lid disappears, the cornea clears up, and the only vestige of disease which remains is a slight thickening of the lids, and apparent uneasiness when exposed to strong light.

If the owner of a horse that has shown the above symptoms imagines that the disease has finally gone, he will be sadly disappoited, for in the course of six weeks it will return either in the same eye with a similar attack or the other eye may be affected. The attack again runs its usual course, and goes away again suddenly, but leaves the eye in somewhat worse shape than the former attack. This disease got the name of monnblindness, from its periodical return and some supposed influence of the moon. That planet, however, has not, and cannot have anything to do with it.

When a Horse is Most Subject to Moonblindness

The horse is more subject to this disease from the age of four to six years than at any other period. He has then completed his growth; he is full of blood and liable to inflammatory complaints, and the eye is the organ attacked from the peculiar disposition in it to inflammation, the nature and cause of which cannot be explained. Every affection of the eye appearing at this age must be regarded with suspicion. As this malady so frequently destroys the sight, and there are certain periods when the inflammation has seemingly subsided, and the inexperienced person would be deceived into the belief that all danger is at an end, the eye should be most carefully examined at the time of purchase, and the examiner should be fully aware of all the minute indications of previous or approaching disease.

How to Examine the Eye

There is nothing which deserves so much attention from the purchaser of a horse as the perfect transparency of the cornea over the whole surface. The eye should be examined for this purpose, both in front, and with the face of the examiner close to the cheek of the horse, under and behind the eye . The examination of the horse should not be in the open air, but in the stable, standing in the doorway and a little within the door. If any small, faint, whitish lines appear to cross the cornea, or spread over any part of it, they are assuredly the remains of previous inflammation. The other sign of apparent disease is a slight thickening of the lids or puckering towards the inner corner of the eye; a cloudiness, although perhaps scarcely perceptible, of the surface of the cornea, or a hazy circle round its edge; a gloominess of the eye generally, and a dullness of the pupil; or a minute, faint, dusky spot in the centre, with or without little fibre s or lines diverging from it.

General Sign of Defective Sight

Good judges of horses are very often deceived when the blindness is confined to one eye. A horse blind in both eyes will usually have his eras in constant and rapid motion,

ABSORBINE STOPS LAMENESS

from a Bone Spavin, Ring Bone, Splint, Curb, Side Bone, or similar troubles and gets horse going sound. It acts mildly but quickly and good results are lasting. Keeps Harness New and Axles Strong

Imperial Eureka Harness Oil

—gets into the leather. Keeps it supple—looking new and strong as new. Keeps insects and moisture out. Prevents drying and cracking. Keeps breakage and repair bills down. Sold in convenient sizes.

Imperial Eureka Harness Oiler

—makes oiling easy, quick and thorough. Should be in every barn.

Imperial Mica Axle Grease

—prevents spindles wearing thin and hubs getting loose The powdered mica and grease coats both spindle and hub lining with a covering of perfect lubrication that fills all pores and smooths all rough places. Makes loads easier to haul, reduces strain on harness and horses.

Sold in many sizes—1 lb. to barrels.

AMHERST, N.S.

directing them in quick succession to every quarter; he will likely hang back in the halter in a peculiar way; and will lift his feet high as if he were stepping over some obstacle, when there is actually nothing to obstruct his passage, and there will be an evident uncertainty in putting down his feet. These signs are very often overlooked by the carless and inexpert, and a blind horse has been bought as a sound one. In blindness of one eye, litle or nothing of this characteristic gait or manner can be perceived. Although a one-eyed horse may not be eabsolutely worthless for common work on the farm, he is not nearly of the same value as one that sees well with both eyes, being more liable to get into accidents.

One way to ascertain defective sight or blindness in one eye, is to carefully note the pupils of the eyes before the horse is removed from the stable, and as he is led to the door, observe whether they both contract, and equally so, with the increase of light. If the horse should first be seen in the open air, let it be observed whether the pupils are precisely of the same size; and then let the hand be placed over each eye alternately, and held there for a while, and watch if the pupil dilates with the abstraction of light, and equally dilates in each eye.

The eye of the horse is also indicativie of his age and temper. There is placed at the back of the eye a considerable quantity of fatty substance, on which the eye may revolve easily and without friction. In aged horses and in diseases attended with general loss of condition, much of this fat disappears; the eye becomes sunken, and the pit above it deepens. One can also make nearly accurate guess at a horse's temper by a study of his eyes. A small cornea and therefore a large portion of the white of the eye visible, is looked upon with suspicion by some men wro claim from experience that such horses are dangerous. The mischevious horse is slyly on the outlook for the opportunity to do mischief, and the frequent backward direction of the eye is a certain sign that care has to be exercised in handling him. A study of all these signs and symptoms is useful alkie to breeder and purchaser, for many of the diseases and temperaments they indicate are hereditary.

MORE WORK OUT OF TEAMS

Some of the tractor boosters have done horse users a good deal of good by charging the horse with inefficiency. It has made many users of draft horses think more about the matter than they have perhaps in many a day. And they have learned a good many things which will help them to get more out of their work teams without working the teams any harder.

One of the things that nas come out of the agitation for more power on the farm is that more power can often be gained by increasing the number of horses on a machine. There was a time when all the talk was the other way—it was to use the minimium number of horses. It was quite a common argument of implement dealers that their make of grain binder or gang plow could be run with only three horses where the competitor's machine took four. Now we see it is a mistake to operate machines with only three or four horses if a fourth or fifth will get more ground plowed or grain cut. It is not necessary to buy the extra horse, so there is no advantage in saving him. On many farms this extra horse has been turned out to pasture and perhaps got in mischief, whereas he might have been helping in the field.

Care is always a big factor in getting the best work out of teams. Who has not observed that some men have their teams in good shape and seem to get just as much work out of them as others whose horses always show their ribs and seem worked to death? A good horseman will find lots of ways to keep his horses in good temper and condition. You will find such a man on the best of terms with his charges. He will talk to them kindly, worry them as little as possible, adjust the harness properfly, devise a hitch so th elazy horse is made to keep up his end of the evener, lift their collars when they are pulling hard, especially when they start spring work, feed and groom them well, and in numerous ways make their work as easy as possible, at the same time getting the most work out of them.—Drover's Journal.

RIGHT WAY TO PICK UP A HORSE'S FOOT

There is more than one safe way to pick up a horse's foot.

"In picking up a hind foot," says an army officer, "the man should stand with his outside foot advanced and his inside hand on the point of the horse's hip; run the outside hand down the outside of the leg, working to the back of the leg, below the hock, until the hand is just above the fetlock; push slightly against the hip with the inside hand to induce the horse to shift his weight, and raise the foot by pulling it forward and up. When the foot is raised swing the inside foot forward—to the horse's rear—and support the horse5s foot on the knee.

"If an extended examination or one in which it is desired to use both hands, is necessary, the outside foot can be brought alongside the foot supporting the horse's foot and the latter can then be rested on both knees. I never place the hind foot between the knees—only the front foot.

"In raising a front foot use the hand nearer the horse and induce him to shift his weight by leaning as heavily as necessary against his shoulder."

WATCH THE SHOULDERS

As hot weather is now coming on, farmers will have trouble with their horses' shoulders galling. In case of severe gall, many farmers turn their horses out till they heal, thus causing inconvenience and expense to the owner of the horse, as he cannot well agord to lose the service of his horse at this time of the year.

We find in the case of a gall it is not necessary to lose the service of the horse, but it can be worked every day and shoulders cured by using a good grade of talcum powder. When working the horse, watch the shoulders closely, and every time the galled place shows signs of dampness sift talcum powder on it till it becomes dry. Keep the part of the collar pad that rests on galls thoroughly clean. By following above direction the farmer can work the horse every day and cure the galled shoulders.

Avoid all grease and salves of every kind while working the horse, as it only tends to irritate the place.

Horsemen Attention !

Dr. J. Woodbury's Horse Liniment and Dr. J. Woodbury's Condition Powders will save and preserve the life of your horses. Their use will cure and prevent the disease common to horses, such as Cough, Colds, Distemper, Spavins, Pinkeye, Splints, Curbs, Enlargements, Cracked Hoof, Kidney Trouble, Fevers, Cuts, Sores and will remove bunches of all kinds.

BEFORE USING

Why have a sick or lame horse, when you can get a reliable and warranted remedy? The leading horsement of the Dominion endorse Dr. J. Woodbury's Horse Liniment.

FOR SALE ALL DEALERS

PRICE 35 CENTS

Do you know that "Dr. J. Woodbury's Horse Liniment" is endorsed by all the leading horsemen of the Dominion. Save and preserve the life of your horses by its use. It will cure and prevent disease common among horses.

DEMAND

POULTRY.

FEEDING YOUNG TURKEY POULTRY

Turkey poults should be fed often—four or five times a day—and just a little at a time for the first few weeks. Cracker crumbs, oat meal, cracked corn, wheat, stale bread soaked in milk, etc., are excellent at first. Gradually add wheat middlings (sorts), mixed moist but not sticky. Add oats to the grain ration, and begin to use whole corn instead of cracked as soon as possible. The poults should have ground bone or meat scraps and green food for vegetables suplied to them regularly if their range does not afford a plentiful supply of these materials. Sour milk or buttermilk is good for them at all times.

While turkeys being fattened should not have such a large range that they can "run off" their fat, they do not do well when confined to small coops such as may be used in fattening chickens. Limited range is better. Turkeys are great bug, worm and seed eaters and if allowed to wander a long way from home for feed they do not fatten so well as where their roaming is curtailed by liberal feeding. Especially when the weather begins to turn cold and insect food scarce in the fall, and increased grain diet must be provided for the growing turkeys.

As soon as the turkeys become accustomed to a heavier grain feeding, they may be fed once or twice a day on ground oats, middlings and corn meal moistened with milk. Corn and oats (also wheat when it is not too expensive) should be given in addition to the mash. Provide the birds with plenty of drinking water at all times.

Some successful feeders use a mixture of equal parts of ground oats, barley and corn, with table scraps, boiled vegetables mixed with milk. Vegetables fed freely have a tendency to make flesh plump and white.

In marketing turkeys it pays to have them well fattened and well dressed, so they will look better than the average. Attractiveness goes a long way in selling market fowls. Do not give food to the turkeys for twenty-four to thirty-six hours prior to killing; full crops and entrails taint the meat and prevent its being kept for any length of time without spoiling.

In dressing turkeys for city markets do not remove the head, feet or entrails, but have the whole carcass, including head and feet, perfectly clean. Kill by sticking a sharp knife into the base of the fowl's brain, through the mouth, instead of chopping off the head.—B. Sando.

GIVE TRAVELLER CHOICE OF ROUTING TO WESTERN CANADA

Additional facilities are now offered passengers who desire to travel between Eastern and Western Canada via Montreal and Toronto. The traveller may leave points in the Maritime Provinces via the "Ocean Limited," daily except Saturday, and connect at Montreal with the "International Limited" of the Grand Trunk Railway System for Toronto. An exchange system has been arranged between the Grand Trunk and Canadian National Railways with regard to tickets between Toronto and Winnipeg and beyond. The traveller now has the choice of routes and may travel on the famous train "The National," via North Bay and Cochrane or on train "Number One" via Capreol and Port Arthur. "The National" leaves Toronto 9.15 p. m. Monday, Wednesday and Friday, arriving in Winnipeg 6.00 p. m. Wednesday, Friday and Sunday. Train "Number One" leaves Toronto 9.15 Tuesday, Thursday and Saturday, arriving in Winnipeg 6.00 p. m. Thursday, Saturday and Monday. Both these trains carry Standard and Tourist sleeping cars, dining car, first class and colonist coaches. This exchange system of tickets provides a daily, except Sunday service from Toronto to Winnipeg. Ticket exchanges are made without charge by the Agent at Toronto Station. In adition to this the Grand Trunk operates a double daily service between Montreal, Toronto, Detroit and Chicago, where convenient connections are made for points west, affording passengers a wide choice of routes to Western Canada.

FOWL CHOLERA AND ITS TREATMENT

Fowl cholera and roup usually make their appearance at two seasons of the year, spring and fall. Many times fowl cholera will make its appearance when the weather warms up and we have a thaw. This is especially true where the birds are turned out on nice days. Roup is apt to appear any time when the birds catch cold.

This year, however, we are beginning to receive a great many letters from practically every part of the country giving symptoms of sickness in poultry. In practically every case it is very easy to see that fowl cholera is the cause of the trouble.

It is almost impossible to diagnose an acute case of fowl cholera outside the laboratory and be absolutely certain. However, if the birds are lost according to the description given and others continue to be taken sick, it is quite certain that fowl cholera is in your lot. It is well to open the birds that die and look for the following symptoms, although in very acute cases these symptoms are not found. Liver enlarged, very soft and flabby. It may have small cheesy white spots. A large amount of blood around the heart. On the inside of the intestines a reddened condition and congestion of the blood.

The best method of treatment and one that has been used with satisfactory results, is as follows: The houses are thoroughly cleaned and sprayed with a five per cent. solution of standard stock dip. The outside of the house and the ground for a distance around the house are sprayed with the same solution. The chickens are confined so that it is impossible for them to get other drinking water and given only that which has been treated with one 7.3 grain tablet of bi-cloride of mercury to each gallon of water. Care must be taken that metal drinking vessels are not used as bi-chloride of mercury readily attacks metal. Cement, earthenware, wooden, enamel or stone vessels can be used. With this method of treatment in some cases the loss was stopped from the very first.

Three Destroyed
One Roof Escaped

The picture tells the story.
Mr. Offer's letter confirms the fire-resistant qualities of

Brantford
Asphalt Slates

He says:

"I covered the roof of 201 Marlborough Ave., Toronto, with your Asphalt Slates some time ago. This house is one of a row of four, the remaining three were covered with Cedar shingles.

"These houses were close to a railway track and on the night of August 15th, 1918, these roofs caught fire from a spark from a passing train.

"As you can see in the picture, the roofs on three houses were completely burned through, including the sheeting boards and rafters. The boards and rafters on 201 were also burned through, so that the fire passed over and under your slates without harming them in any way.

"I have rebuilt the roofs and covered them with your Asphalt Slates since I have had such good proof that if the four roofs had been covered with your slates no fire would have occurred."

And here is another letter, from G. F. Wingrove of Walsingham, Ont., dated December 2nd, 1918.

Mr. Wingrove says:

"The house I live in is a large frame with dry pine rafters and sheathing. I covered same with Brantford Roofing last May.

"On November 24th, at eight in the morning, we discovered that it was all aflame inside of roof of one part, 18 x 30, with a fine breeze fanning it. But by the use of the telephone and the splendid fire-proof qualities of your roofing, we got the fire out and found spaces where the rafters and lumber were burnt out from in under the roofing and the roofing still doing its duty of resisting fire. Also remember this is out in the country where it took the best part of half an hour for help to arrive."

The Inspector of the Waterloo Mutual Fire Insurance Company, has this to say about Mr. Wingrove's fire:—

"I inspected this risk after the fire. It was particularly evident that the fact that the roof was covered with Brantford Roofing kept the fire confined below the roof. If it had been possible for the fire to break through I do not see how they could have saved the building. As it was the loss was comparatively trifling."

When roofing a building, it pays to put on a fire-resistant roof as well as a beautiful one. Brantford Asphalt Slates (individual size shingles) and Brantford Asphalt Slab Slates (four shingles in one) are fire-resistant, durable, economical and beautiful.

Samples and prices furnished on request.

OVERCROWDING CHICKS

Avoid overcrowding growing chicks. A coop, brooder or colony house that was large enough to hold the baby chicks is not large enough after two or more months, depending on the breed and growth. It is absolutely necessary that growing chicks have

plenty of room to grow. Cockerels that are sufficiently large should be disposed of. Chicks that have not shown proper growth should also be separated and leg or wing banded. Many of these chicks, even the pullets, should be marketed. Only the good, strong, vigorous speciments should be retained as breeders and layers, as these are the only ones that can return a profit.

Growing chicks will not eat too much if they can have plenty of range so they can get the desired exercise. A good growing mash should be accessible at all times to growing chicks. Such a mash should contain plenty of bone meal, ground very fine, and fine-ground oats and barley. Be sure to have the mash ground very fine.

Growing chicks that are kept closely confined need much greater attention along all lines than those that have range. See that they have plenty of green feeds that have not wilted down to almost the decaying point and that the yards are kept sweet. Culling also is more essential when chickens are closely confined.

A CORRECTION

In our issue of June 24th, page 950, in an article, "Does it Pay to Keep Pure Bred Fowl?" the average profit from 29 hens and pullets during 12 months was fixed at $1.17. The gross was $178.94, so that obviously the average was $6.17, not $1.17. We regret the typographical error.

WHITE DIARRHOEA TROUBLING POULTRY

Is there a cure for whitie diarrhoea in hens that are well fed and have a free run on the farm?—R. R.

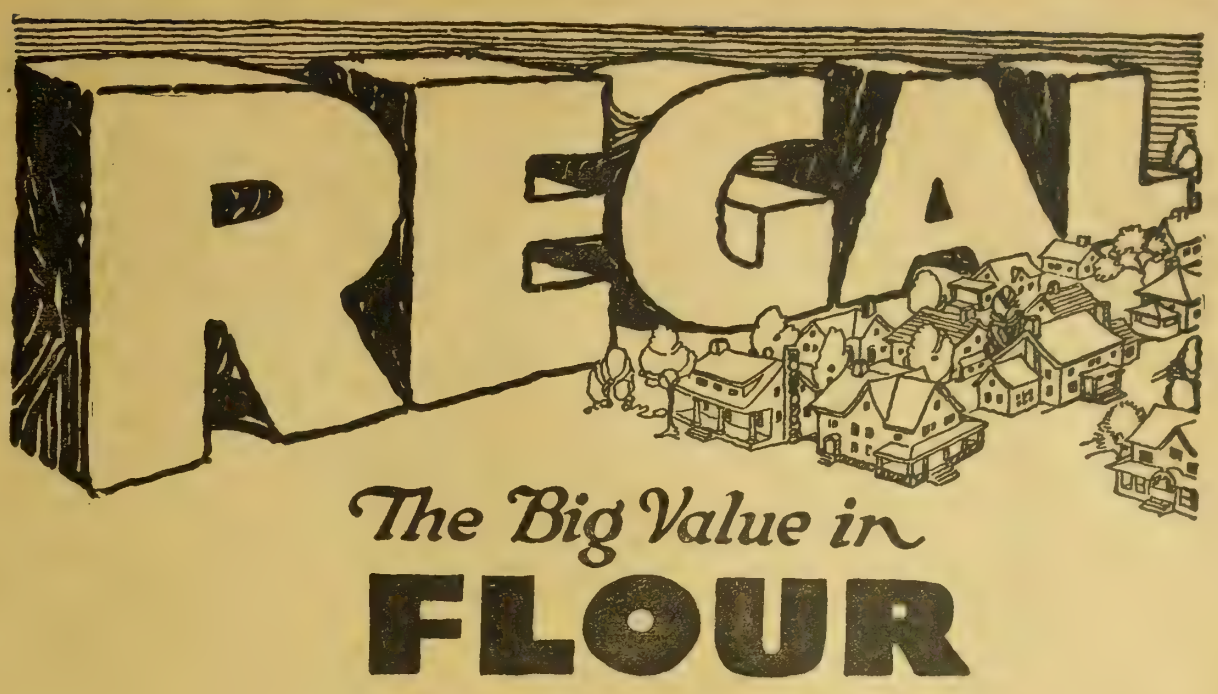
There is no known method for treating poultry affected with white diarrhoea. To keep the disease out of the flock one should never set eggs from hens that had white diarrohea when they were chicks. Eggs for setting should not be sold from a flock where the disease has been present during the former season. Several remedies are recommended, but cases of guaranteed cure have not yet been reported. Care should be taken to isolate all sick birds and burn all those that die.

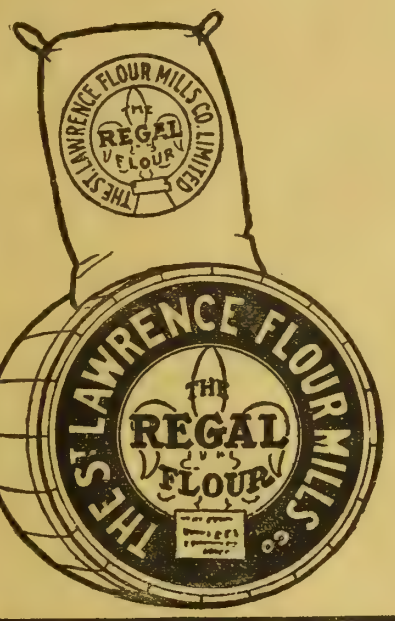
The use of sour milk has been found beneficial, also crystals of permanganate of potash in drinking water to make it a cherry red color. Clean all coops, feeding troughs, and poultry fitings, and then thoroughly spray with chloride of lime dissolved in water to make it a cherry red color. Clean all coops, feeding troughs and poultry house fittings, and then thoroughly spray with chloride of lime dissolved in water. For your young chicks that are affected, put ten grains of iron sulphate to the gallon of drinking water, and feed them with food that has been softened with whey, buttermilk or sour milk.

ROBBING THE FAMILY

When eggs are selling at the grocery for 50 and 54 cents, it is a temptation to the farmer's wife to rob the family of this nourishing food and sell her weekly poultry prduct at the city grocery . But it must be remembered that eggs are necessary food for the farmer's family as well as that of the city man. Especially should the children have plenty of soft-poached or soft-boiled eggs. Eggs, too, should be used in abundance for cooking, such as making custards, puddings and similar foods. It is not the part of wisdom to rob the family of eggs and sell them to purchase other foods not so nourishing and necessary in the family ration.

Mary had a little hen,
But she was very queer:
She laid like fun when eggs were cheap,
And quit when they were dear.





IN THE HOMES of the people, far and near, "REGAL FLOUR" is known for its high and uniform quality; it is known as the most important factor in bread baking success.

THE ST. LAWRENCE FLOUR MILLS CO.
LIMITED
MONTREAL

GOOD TIME NOW TO SELL OLD HENS

Poultry raising in Canada is essentially a farm industry. An average sized flock is easily managed and is not expensive to feed, because so many waste products are consumed. During a part of the year the laying hens and the growing stock can be kept on free range, thus greatly reducing the cost of feed. When given good attention poultry thrive well upon the farm and give good returns.

Up to the present, however, there has been a general lack of appreciation of the value of a farm flock and the importance of the poultry industry. There are too many mongrel flocks in the country today and the result is very low production. One thing which is very apparent among the poultry of the country is lack of vigor. There are few farmers who adopt a system of breeding and as a rule no selection is practised. Rigorous selection should be practised every year, and the conservation of vigor should be the poultryman's standard in selection, which should proceed continually from the time the egg is laid until the birds are dressed for the market or sold for breeding purposes. All cripples and weaklings should be removed from the flock as sheuldbe removed from the flock as soon as they appear to be affected. There is no greater mistake made by poultry raisers today than the practise of keeping old hens and non-layers over the summer. It is bad enough to keep them over winter but there is no excuse for allowing them further feed, care and shelter for which they will never repay. If they do not lay at this season of the year their chances of profitable egg production are gone forever. It is not a very difficult matter to tell the layers at this season, and there is no better time to cull the flock than right now. Prices for pou'try are high and old hens are very much in demand at present, consequently it would seem like profitable business to have a regular clean-up before the warm weather arrives and prices fall. Old hens are useless as far as egg laying is concerned, and they should be replaced by younger and more profitable stock. Their value as breeders is not desirable for since they themselves are poor layers there is little chance that their offspring will be much better. The profitable laying hen is short lived pends largely upon rigorous selection but the poultry industry appears to demand the closest scrutiny of all. The profitable layinghen is short lived and selection is thus an endless process.

Young turkeys should not be allowed to run with mature birds if any of them have previously shown any symptoms of having had the diseases known as blackhead.

"Alfalfa should be cut for hay when the shoots are starting from the crown, which is usually when it is one-tenth in bloom," says the Extension Division of North Dakota Agricultural College. "If cut too early. weeds may develop ahead of the alfalfa, and if cut so late that the young shoots will be clipped off the next crop will be injured.

It requires careful management to keep the capital invested in farming alive.

PILES Do not suffer another day with Itching, Bleeding, or Protruding Piles. No surgical operation required. FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N B. solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

CAN—AND DON'T BE DISCOURAGED

A Practical Article to Help Women Who Have Had Trouble with Last Season's Canning

(By Helen Christine Bennett)

I know a number of housekeepers who "just can't wait" to see how their canned goods turn out and who after canning a lot, say eighteen jars of a product, set them aside for several days and then open a jar just to see that everything is all right. I, myself, never do this. If anything is wrong with the goods I have canned in hot July I can stand that knowledge better next winter when I have literally cooled off from my canning excitement. I don't want to know it in Summer just because if anything did go wrong it might discourage me and make me can less. The best thing you can do with your canned goods when they are done, is to forget them. But if you do open a can or if you merely display them with pride to some city visitor, there are certain things that may have happened to them that may cause you needless anxiety just because you do not understand them.

If you find a cracked jar here and there, do not worry. A crack may mean an air leak and it may not. To be safe, get out your parraffin, melt a bit and apply with a clean camel's hair brush across the crack. Put the jar where you can see it and unless little bubbles appear near the crack or at the top of the goods put your faith in that jar and store it away for next winter.

If Peas Are Cloudy Looking

If you are inspecting your canned peas and the jars look muddled or hazy, and the water in which the peas have been canned appears clouded, do not assume that your peas have spoiled. They probably are all right. This clouded or hazy appearance may be due to one of several causes. Perhaps in packing the peas you rubbed off several of the outer skins. As a result, the soft inner part of the peas has cooked to pieces and clouded the water, but it has not harmed the can a bit. To get a clear can of peas, every split, broken or doubtful pea must be removed when preparing for the cans. If the peas to be canned are pretty old, it is next to impossible to blanch a large quantity so carefully that the skins will not crack. Cracked skins make clouded jars. Even in bought canned peas of the lower grades this cloudy appearance is noticeable, and if the professional canners can not avoid it, it is hardly likely that amateurs can hope to. The bought peas are in tin and the clouded appearance is less likely to be noticed than in glass. And even if peas are carefully prepared and are young, it sometimes happens that the water in which the peas have been canned is responsible. Hard water containing certain minerals will give this clouded appearance to canned goods but will not injure them.

Corn is another tricky vegetable. Canned corn often has a cheesy, doughy appearance. It may even stick in little lumps in places on the sides of the jars. But even so, it is not dangerous and will taste quite as well. The cheesy appearance means that the corn was packed when it was a little too old for perfect results. But for making soups and fritters or for baking as a pudding that cheesy part will be just the thing wanted. If, on the other hand, the corn appears watery and pale it means that it was blanched and packed too slowly and that the packing was too loose, allowing too much water to be used. The best results on corn mean quick work, rapid moving from blanching to cold dipping and from that to packing. Do a jar at a time and put it at once into the canner. Two women should work together at this job for good results.

If canned beets are sickly looking and rather pale, they will probably taste just as well as if they were a vivid crimson. The fading means that they were old when packed, although certain varieties of beets hold their color at any age. To prevent faded beets, use smal beets, as small as 40 to quart, and can them whole. When they are blanched, leave on all of the tail and an inch of stem. Scrape them, never peel them, after cold dipping them and then cut off your inch of stem and the beet tail. Do this if you want perfect beets. But if you are hurried and busy, and your beets are too big for this, why just leave on the skin and tail, blanch them and cold dip them, and then cut off the ends and peel them and cut them into pieces—after which can them as fast as you possibly can move and when you have finished them shroud them in paper bags. All authorities to the contrary, I have had beets cut in this way a perfect crimson on the table. Be sure the water you pour on the slices is boiling hot.

Nearly every housekeeper I know worries because her jars are not full after canning. I have canned a few jars where the product did not shrink, but when one is hurried and is trying to conserve fuel, perfect packing and keeping the water just one inch above the canning product is something of a task. I have watched the demonstrators pack so as to avoid shrinkage and if I had to spend that much time packing a jar I would have to give up canning. Also I confess that the water in my homemade canning outfit sometimes boils under the jars before the jars are done. I tried adding water, but several times I cracked jars when I poured water into the canning outfit, so now I let it alone. As a result most of my jars have a vacuum at the top, of which I am supposed to be properly ashamed, but of which I am not. For unless you are trying for a prize at the fair that vacuum is not going to hurt you or anyone. @reens, such as spinach are likely to shrink tremendously unless the blanching is very carefully done. To blanch greeens properly they must be done in steam and never touch water and this means using a steamer or some specially constructed vessel with a rack that keeps them well above water. I am bound to say that care in this matter of blanching greens pays, as the canned greens are much better in flavor and are higher in nutritive value than greens that are blanched in water.

When Food Seems Spoiled

One of the greatest worries a housekeeper has about canned goods is the uncertainty as to whether canned goods are actually spoiled and unfit to eat. I do not want to run the risk of poisoning any family by advocating certainty before throwing away a can, but if a can seems doubtful, the best test is to heat the contents slowly and for a long time. The heat nearly always makes the spoilage a certain thing, and if after long heating the contents taste all right they are fairly certain to be safe. Heating a long time at a simmer, is also fairly certain to destroy dangerous bacteria and so make a safer content.

To Cure "Flat Sour"

The re is one defect in canned foods which no doubt has caused the throwing away of thousands of cans, a defect which does not seem dangerous, but which does affect the flavor of the canned goods. This is what is technically known as "flat sour." The goods which are "flat soured" seem all right, only they have a sourish odor and taste. "Flat sour" affects peas, corn, beans, and asparagus more than other vegetables and is particularly offensive when masticating the skins of these vegetables. It may be due to many causes, principally to canning vegetables that have been picked for some time and upon which bacteria has had a chance to work. It is not always possible to get strictly fresh vegetables to can, so that I am going to suggest that housekeepers who can these products do what professional canners do when they can not obtain a strictly fresh product, that is, use sugar or a thin sirup made with sugar to pour over the produce in place of plain boiling water. I put 1 tablespoonful of sugar to a quart in doing this, but I am not certain that this just the right amount, although the jars thus treated were much better than those untreated with sugar. The housekeeper who tests this out may experiment a little to find her right amount. Corn, almost all corn, I found much better and much less likely to "flat sour" or to taste "flat sour" when so treat-

ed. I have had no trouble with beans, but I do intend to use sugar with all asparagus, as I have had a good deal of trouble with "flat sour" with it.

Rapid blanching and cold dipping, that is, doing these full time but not losing any between operations, and rapid packing and immediate putting in the canner help in avoiding "flat sour." Another great help is the rapid cooling of the jars when they are taken from the canner. It is a common practise among my neighbors to tighten the lids, but to let the jars remain in the boiling water, standing there on the false wooden bottom until they are cool enough to handle with no danger to the hands. This slow method of cooling not only tends to help "flat sour" but it is apt to result in cloudy cans, in mushy contents, and badly shaped contents as well.

For this reason wire racks with handles which permit the hot jars to be lifted out are well worth their price.

As you read you will wish, I suppose, that I had given all this advice earlier in the season.

But even if you have cans and jars that have "flat soured," do not despair, and do not throw them away. I take all my "flat soured" cans and sweeten the contents and cook them slowly. The addition of some definite flavoring helps. Chopped mint added to peas gives a flavor which many people like. Onion juice or browned onion cooked with any vegetable helps with the flavor. Pimentoes or Spanish peppers help flavor beans. One of my own favorite flavorings is made from dried celery tops kept until they have fallen to small pieces. This celery flavor seems to fit many vegetables. Flavoring is also needed with vegetables which have not "flat soured" but which have a flat taste, rather flavorless. This indicates that blanching was not properly done or that cold dipping was omitted or that too much water was used with the vegetables to be canned. ometimes it means none of these, but simply that the vegetables to be canned never had a very good flavor. The wise woman keeps at least one bottle of first class kitchen sauce upon her shelf for just such emergencies. In addition, there are the helps I have already indicated. Because of the need of these, it is a good plan not to wait until the last minute to open your canned goods, but to open the jars a few hours or even a day before using.

This last year, when we practically lived on my canned goods, I found that the leftovers from the day before tasted much better than the freshly opened goods, and so I fell to opening my cans a day before and to treating them. if treatment was needed, ahead of the time they were to be served. Even fruits appear to benefit by the chemical action of the air upon them.

Mold on Canned Goods

If your fruits show mold, do not be discouraged about that. Mold isn't dangerous. It is a vegetable growth, usually harmless, although I do not advise eating it. Scrape off the mold, cook the jar contents slowly and you will find them safe. Even if a jar has started to ferment, and is caught in time, there is nothing but a rather pleasant taste, the result of the formation of a small quantity of alcohol, and the canned goods are not harmful. Mold usually develops because the seal is defective. If mold is spreading through a large quantity of jars it may be entirely possible to scrape off the mold, remove the contents, re process them in clean jars with good rubbers, and have them keep well. Opening the jars after canning to put on the rubbers is responsible for much mold. Housekeepers must learn to keep rubbers on jars while they are being boiled. They must also be sure to use good rubbers and test them if they are in any uncertainty. The Department of Agriculture attributes thirty-five per cent. of the spoilage of jars last year to the use of poor rubbers. I buy the best rubbers I can buy, boil them hard for some time, say twenty minutes, and then I cool them and pull them about. If they do not seem elastic I do not use them. It pays to be certain of your rubbers.

Jar breakage is very often not due to defective jars, but to poor handling. Pouring boiling water into the jars is a dangerous process, and the

Children's Diseases Are *Not* Necessary

They Add Nothing to the Well-being of the Child and Invariably Leave the System in Worse Condition Than Before They Came

IN fact, they often sow the seed which, in adult life, develops into disorders of the heart and blood vessels and degenerative diseases of the kidneys.

So if children escape any child's disease they are the gainers in general health by just that much. It may be that years are added to their lives or chronic invalidism avoided. Then there is the enormous risk which every child runs who has measles, whooping cough, scarlet fever, or other diseases.

Perhaps this does not agree with your idea of letting your children have these ailments when young, with the belief that they must have them some time. This old idea has cost many thousands of lives. It is time to forget it, and to put forth an effort to save the children from these ailments.

All these children's diseases are known as germ diseases, and germs are harmless to a body strong enough to fight them!

Rich blood is the greatest of germicides. Therefore, seek to keep your children's blood rich and pure by giving them wholesome, nourishing food, and by allowing them to exercise freely in the open air.

If they grow pale and weak and languid —if they fail to derive proper nourishment from the food they eat—if their nervous systems get run down from the tax of school work—use Dr. Chase's Nerve Food as the best means which medical science affords to enrich the blood and build up the exhausted system.

Children whose blood becomes thin and watery are helpless before an attack of measles, scarlet fever, whooping cough, or other contagious disease. They seem to "catch" everything that is going. They are always "catching" cold. Their resisting force is nil.

But their young bodies soon respond to the nourishing, invigorating influence of Dr. Chase's Nerve Food. As their blood is enriched they become healthy, robust and rollicking—they enjoy their food—their play—their work at school, and grow into strong, healthy men and women.

Dr. Chase's Nerve Food, 50 cents a box, 6 for $2.75, all dealers, or Edmanson, Bates & Co., Ltd., Toronto. On every box is the portrait and signature of A. W. Chase, M.D., the famous Receipt Book author.

Table of Sirup Density

Per cent. Density	Part sugar by pounds	Part water by quarts	Use for

IS YOUR LIVER OUT OF ORDER?

HOW TO TELL.

Unless the liver is working properly you will find that a great many troubles will arise, such as constipation, heartburn, the rising and souring of food, which leaves a nasty bitter taste in your mouth; then again there is a sort of watery substance, that comes up in your mouth from time to time and which has a sweetish taste; specks float before the eyes and for a few seconds you feel as if you were going to fall down in a faint, your tongue is heavily coated, your head aches, you become bilious on account of too much bile forming in the stomach; your food does not agree with you and a thousand and one other things seem to be the matter with you.

YOUR LIVER IS OUT OF ORDER

Milburn's Laxa-Liver Pills are a specific for all diseases and disorders arising from a slow, torpid, lazy or sluggish liver, as they clean away all the waste and poisonous matter from the system. Price 25c. a vial at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

water should should always be poured on the par contents, not on the jar itself. But many jars are broken in cooling. I have advocated rapid cooling of jars, but this does not mean that they are to be taken from the hot water and carried to a cool pantry nor should they be set in a draft. Cool them in a warm kitchen first and much breakage will be avoided.

The matter of sirups on fruits has worried me for some three years. I could not seem to get the matter of sirup density straight. So I have made a table which it seems to me fits better than any table I have yet seen. It is not scientifically accurate to the elast ounce, but it will work well. It includes the amount of sugar for sirups of different densities and the lists of fruits for which these sirps are used. It is given in the accompanying table:

You will not need all this advice perhaps, just now. But when company arrives this summer, and you are in a hurry, you will find yourself opening a jar now and then and I am so afraid that if the jar is not all that it should be, yo uwill become discouraged and not can any more this fall. I have known so many housekeepers to give up. You cannot afford to give up.

There is no royal road to canning and you must learn the ordinary pathwaq, for the country is going to need your help in keeping foods for some years to come. The sooner you make up your mind to master the trade, the better.

SUMMER BEAUTY HELPS

(By Alice Lane))

This is the time of year when the woman over thirtty has to be doubly careful in the little things that go toward making her well groomed.

The girl in her twenties can let her hair fly wild, she can expose her skin to the winds and sun because youth has many weapons to fight the elements, but once you are thirty, the little thiings are really more important than the big ones.

Where beauty is concerned, cleanliness is the greatest thing in the world. Never fail to take a daily bath; shampoo your head a little oftener than you do in the winter and use your creams and lotions many a time and oft.

Perspiration is one of the greatest annoyances we have to encounter once the hot, sultry days are with us. But the point in favor of that is that we can buy a bottle of an astringent lotion that stops all excessive perspiration. I think there are still some women afraid to use these lotions, but such women are back numbers. Properly applied they are wonderful. You apply the lotion under the arms— on the palms of the hands if they perspire, and I knew a woman who used it on her upper lip for years. Many women use it on the back of the neck. In fact this lotion is perfectly safe and efficacious to use on any part of the body where you have excessive perspiration. First apply it, and let it dry for a few mintes; follow with a goodly dusting of talcum, and you will have no trouble. But you must let it dry, or else it will play havoc with your dainty summer underwear. When first you begin to use this lotion, it may be necessary to apply it every day, butafter a while you will find t wo or three aplications a week are sufficient.

If you are inclined to have the slightest odor from perspiration. you can absolutely kill it with a lotion, salve or powder, all manufactured expressly for that purpose.

Manicuring at Home

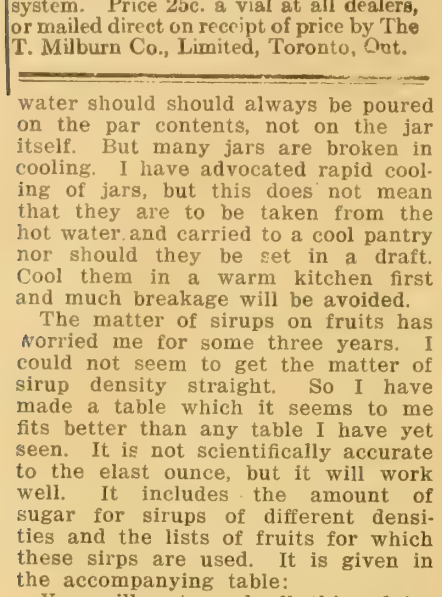
Now is the time you are apt to abuse your hands. You are digging in the garden, working over the automobile, and doing all sorts of odd jobs that are fatal to the appearance of the hands unless you take good care of them. Hence you must do a lot of home manicuring, and do it every day. Ugly, red, and rough hands do not go well with a dainty summer frock. Keep the nails filed round, following the shape of the finger tips, but do not use a file under the nail. Orange sticks must be used for that. Wrap a piece of cotton around the orange-stick and dip in a solution of peroxide or any good nail-bleach and clean the nails in that manner.

Do not be so old-fashioned as to attempt to cut your cuticle. In the first place you can not do it properly yourself, and in the next place it is not necessary, for you can get a bottle of cuticle-remover for a small cost. Use your orange-stick with cotton, dip in the cuticle-remover, and run around the edges of your nails. Let it remain on a few moments, then scrub the nails in soap and water and dry thoroughly, pushing back the cuticle about the base of the nail. Ten minutes a day spent on your nails with the proper kind of a home-manicuring set will keep them in perfect condition.

When you come in from a long automobile ride and your face is dirty, don't rush to the basin and scrub it with soap and water. To be sure, you will succeed in getting it clean, but your skin will be dry, your face will be red, and you will have a burning sensation. Wash the face in witch-hazel, pat it dry, and then apply some cold-cream. This should be wiped off with a soft piece of linen. Then dust with a good face-powder.

I doubt if there is any preparation that will permanently remove any superfluous hair on the arms upper lip, etc. But there are any number of harmlss preparations that will remove it for a time. Bleaching the hair on the upper lip makes it less conspicuous, and is a perfectly harmless thing to do. Mix equal parts of ordinary household ammonia and peroxide. With one hand hold your nose so you do not breathe the fumes, and with the other rub this mixture on with a piece of absorbent cotton. Let it dry on the lip—do not wipe dry. Do this once a week.

And, finally, how many of yoh have a piece of pumice stone on your wash stand, and how many of you know of its many uses? A lot of women have hair on their legs, and it does not look very pretty showing through thin, white silk stockings. Every time you take a bath, when the skin is still wet, rub the salves of the leg with the pumice stone. You will be surprised to know how efficacious this is. if you keep on doing it, and surely the treatment is perfectly harmless. If you have to stand a good deal during the day, and your feet ache, be sure you bathe them every night in hot water in which a sprinkling of washing soda has been dissolved. Then rub the soles and any callous spots with wet pumice. If your feet perspire exessively, any druggits will sell you a powder which can be dusted into the sole sof your shoes to offset that nuisance.



Clean to handle. Sold by all Druggists, Grocers and General Stores.

ON CANNING AND CURING OF MEATS

To can pork and beef cut the pieces as you do when serving for the table. Pack them closely in two-quart jars, putting in also one tablespoonful of salt in the centre of the jar. Cut up pieces of suet and put on top to prevent moulding. Do not put a drop of water in the jar as it gets plenty of juice from the meat, which makes a good gravy when weakened with water. Put the rubbers and lids on the screw tightly. It sometimes happens that the rubbeds pull out. When they do so, is it all right to take off the lid and put new rubbers on. Have a board that fits the bottom of the boiler. If you have no board, put a thick layer of rags on the bottom, as otherwise the jars will crack. Pour in cold water until it reaches the lid of the jars. Cover the boiler, anw after water once begins to boil keep the jars in three hours. The jars may be left in until cool but some prefer to take them while hot and see if any rubbers have pulled out. Placed in th ecellare the meat will keep just ah well as does fruit.

As to a meat -curing recipe, the meat should be allowed to get thoroughly cold, but be sure it is not froz-

I KNOW A WOMAN'S SUFFERINGS

I am a woman.

What I have suffered is a far better guide than any MAN'S experience gained second-hand.

I know your need for sympathy and health.

And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.

Are you unhappy, unfit for your duties? Write and tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.

If you suffer from pain in the head, back, or bowels, feeling of weight aud dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creeping feeling up the spine, palpitation, hot flashes, weariness, sallow complexion, with dark circles under the eyes, pain in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your own home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

Read My FREE Offer:

To Mothers of Daughters. I will explain a simple home treatment which speedily and effectually dispels green-sickness (chlorosis), irregularities, headaches and lassitude in young women, and restores them to plumpness and health. Tell me if you are worried about your daughter. Remember it costs you nothing to give my method of home treatment a complete ten day trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. Is health worth asking for? Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your feelings, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

MRS. M. SUMMERS, Box 309 Windsor, Ontario

Kidney Disease
WAS OF A
DROPSICAL NATURE.

No one can be healthy with the kidneys in a diseased or disordered state. The poisonous uric acid which it is their duty to filter out of the blood is carried into the system, and produces all kinds of kidney troubles, such as backache, weak, lame or aching back, rheumatism, swelling of the feet and ankles, urinary disorders, bladder troubles, headaches, etc., and unless these are attended to promptly, serious complications are sure to arise and perhaps develop into dropsy, diabetes, Bright's diseases or other serious kidney trouble.

Mrs. Abel Corkum, East Berlin, N.S., writes:—"I was a great sufferer from kidney disease, headache and constipation. The trouble was of a dropsical nature as my legs would swell up and I could scarcely walk. The doctor did not seem to help me, so I started to use Doan's Kidney Pills. It took about five boxes to effect a complete cure, and I am satisfied that the cure is thorough."

Doan's Kidney Pills are 50c. a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

en. If it does freeze, thaw it out in the house. Cut the meat in small pieces, pack in layers in stone jars, putting enough salt on it to cover it. Put another layer of meat in, more salt, and so on until full. Make a brine of cold water and salt so strong that a fresh egg floats on top. Cover all the meat pieces, and add a tablespoonful of saltpeter with each three gallons of brine. When the meat has been in this brine it will turn red and thick. The meat will spoil if left in this when the weather is warm. Boil it up in the spring before hot weather. The sediment will rise to the top as soon as the brine is heated, and can thus be skimmed off. Watch it closely because as soon as it boils the sediment will sink to the bottom; keep it skimmed off until no more rises. When you have heated all of your brine in this way and skimmed it all well, pour it on the meat.

Go through this same procedure several times in the summer and pouwill have no trouble. It is a good idea to put the meat to soak over night in skimmed milk, as it gives it a better flavor- I have kept meat that has been handled in this way for twenty-two months.

Nova Scotia Man Is Enthusiastic

FOR DODD'S KIDNEY PILLS HAVE MADE HIM WELL

A Year of Growing Kidney Trouble Brought Bright's Disease but He Found a Help in Dodd's Kidney Pills.

Belleville, Yarmouth Co., N. S.,—(Special)—"You can tell everyone that it was Dodd's Kidney Pills that made me well." This is the joyful remark of Mr. Alcide Meuse, a well-known and highly-respected resident of this place. Mr. Meuse, who suffered for a year from kidney trouble, is enthusiastic in his praises of Dodd's Kidney Pills. "I think everybody ought to use them all the time," he says. Then he gives the reasons for his enthusiasm.

"I first caught cold," Mr. Meuse states, "and kidney trouble followed. My sleep was broken, my eyes were puffed and swollen and I had dark circles around them. I was often dizzy and always thirsty. My skin itched and burned at night. I was troubled with nervousness and my limbs were swollen.

"I had cramps in my muscles, backache and headache. Then Bright's Disease developed. A doctor attended me but the first real relief I got was from Dodd's Kidney Pills. I took eight boxes of them and they cured me."

All of Mr. Meuse's troubles came from sick kidneys. Dodd's Kidney Pills cured his kidneys and he felt well all over. That's why he's enthusiastic. For sound kidneys make pure blood and pure blood is the foundation of health.

SPICED RHUBARB MARMALADE

Wash the rhubarb and cut up without peeling. Cook in very little water until soft. For each quart of rhubarb add 1 pound of sugar, 1 teasponnful cassia, ½ teaspoonful cloves. Stir the sugar and spice into the rhubarb and cook very slowly until evaporated one-half its bulk. Put in jelly glasses and cover with paraffin. If desired, raisins may be used with the rhubarb. Use 1 cupful raisins to one quart of rhubarb.

SUN COOKED STRAWBERRIES

Take equal parts of berries and sugar. With one part of berry juice cook the sugar until a thick syrup is formed. Put the berries on shallow trays and pour the syrup over them. Place in the hot sun and cover with glass. Keep in the hot sun until the berries are plump and the syrup jellied. If requiring two or thrre days, take in at night. If rain comes during that time, place the fruit in a very low oven. In this way the process will not be retarded.

STRAWBERRY JELLY

1 pint of juice.
3½ cupfuls sugar.
Juice of one lemon.
1¼ tablespoonful gelatine.
1/3 cup cold water.

Soak the gelatine in cold water. Heat the juice very hot, pour on the gelatine and add the sugar. Stir until dissolved.

Strawberries will not make jelly without either gelatine or pectin, but often a little juice map be made into jelly in this way and used as a dessert if chilled and garnished with whpped cream.

STRAWBERRY AND PINEAPPLE CONSERVE

2 cupfuls strawberry.
Sugar.
2 cupfuls shredded pineapple.

Cook the shredded pineapple in the least possible quantity of water. When tender add the strawberries and cook until they are soft. Measure the fruit and add three-fourths as much sugar as fruit. Cook until it falls in heavy drops from a spoon. Pour into sterilized glasses. Seal with paraffin and cover.

APRICOT PRESESRVE

1 pound apricots.
1½ quarts water.
2 pineapples.
Sugar.

Wash the dried apricots and soak them in water. Cook until tender, using the water in which they were soaked. Press through a strainer. Cook the shredded pineapple until tender, using as little water as possible. Combine the fruits. Measure them and add ½ as much sugar. Cook until mixture fals in heavy drops from the spoon. Pour into sterilized glasses; seal and cover.

RHUBARB JELLY

Wash, cut and cook the rhubarb with very little water until soft. Drain the juice and add equal parts of sugar and the juice of one lemon to every quart of juice. Cook as any other jelly. This is a very sour jelly for meats.

FLEET FOOT

brings City Styles to Country Homes

FLEET FOOT Shoes enable women and girls on the farms to wear the same smart summer footwear as their sisters are wearing in the cities.

FLEET FOOT Shoes are restful, comfortable, and carefully made for sturdy wear—and their low price enables you to have several pairs for the price of one pair of leather shoes.

There are also FLEET FOOT Shoes for men and boys, for work and play, for every member of the family.

CANADIAN CONSOLIDATED RUBBER CO. LIMITED
DOMINION RUBBER SYSTEM
AND ASSOCIATED COMPANIES

Ask your dealer for FLEET FOOT Shoes.
The name is stamped on each pair.

21

SPICED CURRANTS

4 pounds curants.
2 pounds brown sugar.
1 pint vinegar.
1 tablespoonful allspice.
1 tablespoonful cloves.
1 tablespoonful nutmeg.

Wash the fruit, then stem it. Prepare a syrup of the sugar, vinegar and spies. When the sugar is dissolved, add the currants; cook the mixture for 30 minutes. Pour into sterilized jars or bottles; seal and cover.

RHUBARB AND FIGS

5 pounds rhubarb.
5 pounds sugar.
1 pound figs.
Juice and rind of four lemons.

Cut the rhubarb into inch pieces; chop the figs, and cut the lemons in thin slices. Remove the seeds. Add the sugar and cook slowly one hour. When done, put in jelly glasses and seal with paraffin. This combination of rhubarb and figs makes a delicious preserve.

RHUBARB AND ORANGES

1 quart rhubarb.
1½ pounds sugar.
5 oranges, pulp and grated rind.

Cook very slowly about one hour.

RHUBARB JUICE

Cook the rhubarb unil soft; strain. For every quart of juice use 1 pound sugar and the juice of one lemon. Boil slowly ten minutes and bottle. This is a delightful summer drink.

RHUBARB CONSERVE

3 pounds rhubrb.
3 oranges sliced fine.
3 pounds sugar.
1 pound raisins.
½ pound pecans or other nuts cut fine.

Cook slowly three-quarters of an hour or until very thick. When the conserve has reached the desired consistency, put in jelly glasses and cover with paraffin, Store forwinter use in a cool, dark closet.

Minard's Liniment Co., Limited.

Dear Sirs,—This fall I got thrown on a fence and hurt my chest very bad, so I could not work and it hurt me to breathe. I tried all kinds of Liniments and they did me no good.

One bottle of MINARD'S LINIMENT, warmed on flannels and applied on my breast, cured me completely.

Rossway, Digby Co., N. S.

HINTS FOR MOTORISTS

by ALBERT L. CLOUGH

Editor Motor Service Bureau Review of Reviews...

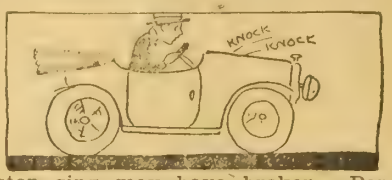
YOUR CAR'S PRIVATE FIRE DEPARTMENT.—BETTER TO BE SURE THAN SORRY

You probably carry a fire extinguisher on your car. If you do not, you are grossly negligent and are paying unnecessarily high for for your fire insurance on this account. Have you looked recently to see if there is anything in your extinguisher? Sometimes the fluid leaks out gradually and all escapes and sometimes a meddlesome person or a practical joker discharges the fluid, returns the extinguisher to its place and does not tell the owner to whom "ignorance is bliss" until a fire starts. Are you sure that the extinguisher will work properly? You can find out by removing it from its bracket, discharging its contents into a can and then returning the discharged liquid. An extinguisher that has been carried for a long time ought to be tested, so that unjustified dependence may not be placed upon it. Do other people, who drive your car, know how to detach the extinguisher, how to operate it and how to place the liquid most effectively, If not, they should be instructed. Is the extinguisher kept where it can instantly be reached. It should be, for a few seconds delay may be decisive as to whether your car will be saved or not. If your car takes fire, do not be deterred from trying to save it, by feear that an explosion is imminent, such a thing is very rare. The thing to do is to "go to it", discharging the liquid on the seat of the flames, and the chances are in favor of success.

PLUNGER OIL PUMP MAY CAUSE TAPPING

B. T. W. writes: My engine has a faint knock or tap, which is to be heard at al ltimes, but is most noticeable at very low speeds. The car is a new one and, so far as I know, everything is in good condition . Listening to the engine from various points, gives no clue to location. What do you supose causes this sound?

Answer: As this is a new engine, it is not likely that looseness due to wear can account for it. Have you inspected the valve gear carefully to see that the adjustments are not such as to cause any undue clearance at push rods, tappets or elsewhere. Of course, there is a possibility that a



piston ring may have broken. Perhaps a valve stem may be sticking slightly in its guide. The fan belt coupling may tap on the pulley. If your oil pump is of the pulnger variety, you may find that it is to blame, if there is excessive clearance between the plunger and the cam, which operates it. You would hear such a noise more distinctly at low speeds, because at high speeds other noises would rown it.

STORAGE BATTER INQUIRY

E. E. R. asks: Would three battery cells, taken from an electric vehicle, injure the ignition coil of my car, if they were used in place of the 6-volt lighting battery, furnised with it,

Answer: As they would furnish

the same voltage as the battery originally installed, we do not see how they could. It may be well to remember that these electric vehicle cells are capable of furnishing a much heavier maximum current than three ordinary lighting cells and it might be wel to protect the system against its effects, by the instal tion of suitable fuses, if there is not already some such protection provided.

TEST FOR PROPERLY GROUND VALVES

O. L. asks: What is the best way to tell whether a valve has been ground so that it will be tight,

Answer: The usual way is to take a lead pencil and make a series of

marks, quite close together, directly across the full width of the valve surface. The valve is then placed in position upon its seat and rotated upon it, under light pressure. If, on removing the valve, any of the pencil marks remain intact, it is evidence of the valve to touch its seat at such points. All the marks should be partly erased if the seating is perfect. Another method is as fololws: Apply a light, even coating of prepared prus-

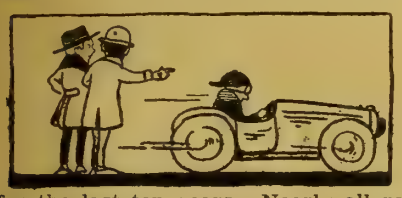
Just like getting a check
-30 cents of each dollar saved!
HASSLERS for all Ford Passenger Cars
HASSLER
TRADE MARK REGISTERED
Shock Absorber
PATENTED
The Hassler Guarantee: "Absolute satisfaction or your money back."
SUPPOSE your garageman gave you a check for 30 cents every time you spent a dollar for tires and repairs? Suppose he gave you a check each year for a third of the depreciation you know has taken place in your Ford Car or Ford One-Ton Truck? It amounts to exactly the same thing when you equip with Hassler Shock Absorbers. At least 30% of your tire and repair cost is saved outright, because the road shocks and vibrations are cushioned before they reach the vital and weighty parts of the machine. This elimination of vibration also reduces the depreciation loss in the same proportion. There is real economy—a real worth while saving! Of course, you know how much more satisfactory your car will ride if you have Hasslers on it. The added comfort alone is worth far more than they cost.
10 DAY TRIAL OFFER
Don't ride without Hasslers because someone tries to discourage you. They are a quality product- worth their price. The Hassler dealer in your vicinity will put them on for 10-days' trial. Your money refunded if you say so. Write for name of dealer and Trial Blank.
HASSLERS "DOUBLE or TWINS"
For Ford One Ton Trucks, Too!
ROBERT H. HASSLER, Ltd.
122 Sherman Ave., North
Hamilton, Ontario, CANADA

sian blue to the valve seat, put the valve in position and rotate it. If contact is good there will be found a continuous blue band around the whole valve face. A blue band with breaks in it denotes a poor job. Valves locater in cages are sometimes tested by pouring a little gasoline into the cage over the valve. If it does not escape betweent the valve face and seat the job is considered tight.

DURABILITY OF HIGH SPEED ENGINES

G. H. B. writes: I am thinking of buying a ————car, but friends tell me that it is drivenu by a very high speed engine and that engines of this type wear out rapidly as compared with those intended for lower speeds. Is this true

Answer: Practically speaking, it is not true. There is no distinct line of demarcation between low and high speed engines. Engine speeds have been increasing gradually and final gear ratios have been growing lower



for the last ten years. Nearly all recently designed cars carry engines that may properly be classed as of high speed. Such engines are mostly of small bore, with very light pistons and connecting rods and well balanced crank shafts and can be operated with at least as low wear and tear, at the higher speeds they are designed for, as the older, heavier, lower speeded engines can be at the speed for which they were intended. You need not worry as to the durability of any of the modern high speed engines so long as adequate lubrication as always provided. Experience shows that, in general, other parts of a car fail before the engine and that the majority of cars become obsolete before their engines are worn out.

VALVE COVER PLATES

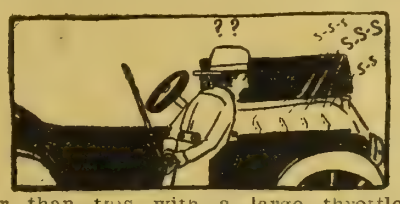
L. P. writes: The engine of my car was built before they had begun to cover in the valves and these are quite noisy. Is it practical to make an arangement to enclose them?

Answer: We have seldom seen an old engine to which it was really feasible to apply valve gear cover plates. There is usually something in the way or there is no good way of fastening them. Still, by taking sufficient pains, a sheet metal cover can usually be designed to afford at least partial enclosure. If you will let a competent sheet metal worker examine your engine, he may be able to work out something for you. Our advice, however, is to keep the valve gear in good adjustment, clean and well lubricated and tolerate the noise.

SPARK TIMING SUGGESTIONS

B. E. S. writes: I am just learning to run a car. How can I tell how to manage the spark to the best advantage?

Answer: You better have the correct position of the spark-lever, for a high gear speed of 20 miles per hour, marked upon the quadrant, by some competent person, when running slow-



er than this with a large throttle opening, the lever should be retarded beyond the emark and always, when the engine knocks. When running much faster than 20 miles per hour, the lever may be set in advance of the mark. Some engines, with certain ignition devices, require hardly any timing of the spark, while others call for considerable.

REPAIRING CRACKED FRAME

The W. M. Co. whites: One of our deliveries skidded down a bank shortly ago, and was badly used up. After making al lthe repairs that seemed

to be required, we noticed that the machine sagged considerably to one side and discovered that one side piece of the frame was cracked. Is there any way that this can be permanently repaired or is it necessary to replace the frame?

Answer: Sometimes an injury of this kind can be effectually repaired by riveting a reinforcing plate over the break and then applying a truss to the under side eof the broken member, with its strut or center piece coming nearly at the break. This truss would be of the kind often used under rear axles, to stiffen them, and would have a turnbuckle in its tension member to adjust it. If the break is where eit can be readily gotten at to bolt or rivete an the rein-

forcing plate and if there is room for the underrunning truss, such a repair is not difficult and is very effective. When applying the plate, the broken member should be jacked up a little ebeyond plumb, before the holes are drilled, in order ta allow for a little sag under load and any sag which later develops can be taken up by tightening the tension member of the truss. We cannot give you details of this repair, without a diagram, but an intelligent repair man can do this work without any trouble, we think, unless the conditions are especially unfavorable.

OPERATIVE COSTS OF CLOSED V. S. OPEN CARS

A. W. C. asks: How much more exensive is the operations of a sedan than that of a car with open body uopn the same chassis?

Answer: Very slightly as a rule. The sedan body usually weighs a few hundred pounds more than the open body, making the closed sar weigh perhaps one-tenth more than the open car. Tire expense increases very nearly in exact proportion to the total weight carried, but fuel expense increases in a lower ratio and you would find the difference, in this regard, rather small in favor of the open car. Interest and depreciation upon the larger investment in the closed car is in excess of of that for the lower priced open car and this item, with the added tire expense, would form the main items on the exces maintenance cost, which we believe you would not find burdensome in view of the advantages of the closed car. . You can readily ascertain just how much heavier the sedan you are considering is than the open car and make your own figures on tire costs.

Better Spark Plugs
For Every Purpose
There is yet to be found a type of motor, a condition, use or industry, where spark plugs are required, that has not been served successfully and efficiently with Champion Spark Plugs. In aeroplanes. In high and low powered motor cars. In low speed tractors with heavy load. In gas engines on farm or in factory. In speedy motor-cycles or motor boats, and in the slower moving trucks, with ever-changing load and road conditions, a "plus service" is rendered by
Champion Dependable Spark Plugs
This "plus service" is made possible by the "Champion" No. 3450 Insulator which has demonstrated its ability to withstand shock, vibration and quick temperature changes to a degree that makes it practically indestructible.
Our patented Asbestos Lined Gaskets are another exclusive feature that cushion the insulator, absorb heat expansion and eliminate compression leaks.
When you see "Champion" on the insulator "that's the plug" that will give dependable service, satisfaction and economy. Every "Champion" is guaranteed to give "Absolute satisfaction to the user or full repair or replacement will be made."
"Aero" Truck JAS 43, ⅞-18, Price $1.00.

THE CARE OF THE FRUIT INDUSTRY

(Continued from page 975)

Some men are disposed to dismiss the question of fertilizers by saying: "My orchard does not need fertilizers." We quite agree with him; in fact, we never knew an orchard or a field that did "need" fertilizers. In fact, the field does not "need" tillage, nor does the orchard "need" care, but the farmer and the orchardist find it profitable to apply proper tillage and proper care. This is the crux of the matter. The use of fertilizers on crops of any sort, including orchards, is not a matter of sentiment or prejudice, but is a cold dollars-and-cents proposition. It should be placed on just the same basis as improved machinery for spraying or tillage. If fertilizers will pay on the orchard, the orchardist should study them carefully and apply them abundantly so that his trees may produce the largest quantity of best uqality fruit.

Ontario orcharding is extensive; in fact, the figures reported by the Bureau of Statistics show that in 1916 over 313,000 acres were given up to the growing orchards, small fruits and vineyards. Now, the yield of apples per tree in Ontario is not by any means as large as it should be. In fact, if an increase in Ontario orchard production equivalent to that obtained on commercial orchards in Ohio Valley could be obtained it would increase the returns in orchard crops in Ontario five-fold, not saying what it would do in the improvement of the quality of the fruit gathered.

Methods of Application

What to apply, when and how to apply it, are interesting points for the Canadian horticulturist. As to the time of application of fertilizers the Pennsylvania Agricultural Experiment Station says: "To increase the crop of the current season the right time to apply fertilizers appears to be about the time the buds are beginning to open in the spring or slightly later. Applications made much later, however, are often useful in steadying the yield from year to year, and hence should not be neglected.

In general practice best results are obtained from fertilizers on orchard trees from applying the fertilizer around the tree, covering an area out from the trunk of the trees about equal to the spread of the overhead branches. This application should be made about the time that the grass is becoming green and taking on a vigorous growth.

What to Apply

As to what to apply, it is generally conceded that a fairly available nitrogen gives quickest results. This should be accompanied by a good supply of phosphoric acid and potash. In Nova Scotia practical orchardists report the use or 500 to 1,000 lbs. per. acre of a high grade fertilizer. This available plantfood assists in early branch growth and bud formation and feeds the developing fruit at a time when the ordinary suply of soil plantfood falls short of the great draft which a heavy crop of fruit makes upon the soil.

Many an acre of unprofitable home or commercial orchard can be brought into profitable yielding by closer care to the five factors at the core of the orcharding industry. None of these factors can be omitted, but not all of them are receiving the attention that thep merit from aCnadian fruit growers. Indications are that considerable opportunity wil develop in the near future for export fruit trade from Canada. Whether or not we shall be able to hold this trade will depend upon the magnitude of the supply of A1 stock. This is why intensive orcharding is of such vital importance to the Dominion.—Canadian Horticulturist.

THE CATTLE MARKET

Montreal, July 5.—At the Canadian Pacific Live Stcok Market the offerings today amounted to 150 cattle, 200 sheep and lambs, 950 hogs and 700 calves. A feature of the trade this week has been the continued demand from American buyers for calves, and shipments of several car loads were made to New York which cost $12 to $14.25 per 100 lbs. This has tended to create a stronger feeling in the market as all surplus supplies of good to choice stock have been taken care of. Another feature has been the demand from Toronto packers for live hogs here and shipments of twelve carloads have been made to them so far this week. This, coupled with the shortage of supplies here to local requirements and the renewed strength in the Toronto market resulted in prices being advanced today 50c per 100 lbs. The demand was good and an active trade was done with sales of selected lots at $23 per 100 lbs. weighed off cars. There was no important change in the condition of the market for cattle, prices being firm under a good demand and small offerings, and a fairly active trade was done with sales of odd choice steers at $13.50 to $14, good at $12 to $13, fair at 11.$50 to $12, and the lower grades down to $8.50, while cows brought from $7 to $11.50 per 100 lbs. There was a good demand for lambs and all the offerings met with a ready sale at $18 to $20 per 100 lbs., but the trade in sheep was rather slow at $8 to $10 per 100 lbs. The market for calves was active at prices ranging from $7 to $14 per 100 lbs. as to size and quality.

MILLFEED AND ROLLED OATS

Montreal, July 5.—The condition of the market for millfeed is unchanged. Supplies of all lines are ample to meet present requirements owing to the fact that the demand is somewhat limited on account of the good condition of the pastures throughout the country, and in consequence the volume of business is rather small. Car lots of bran were quoted at $42, and shorts at $44 per ton, including bags, ex-track, while small lots of bran in mixed cars sold at $43 and $43.50, shorts at $45.50 to $46, feed cornmeal at $70, pure barley meal and mixed grain moullie at $56 to $58, dairy feed at $48, and oat middlings at $44 per ton, including, delivered to the trade. There was no change in prices for rolled oats, and the market was quiet with broken lots of standard grades quoted at $4.25 to $4.40 per bag, of 90 lbs., and Golden cornmeal at $5.25 to $5.35 per bag delivered to the trade.

MALTESE CROSS TIRES
The Farmer's Best Non-Skid Tire
Farmers know that non-skid tires only are safe for wet, slippery or sandy roads. The real, road-gripping kind are the new "continuous tread" Maltese Cross Non-Skid Tires. They have wonderful strength of construction, making them endure to the limit the hard pounding and bruising of rough roads. Made in Non-Skid, Paragon, Ribbed and Plain Treads. Ask your Dealer; he has them or will get them for you.

DAIRY PRODUCE TRADE

Montreal, July 5.—The receipts of butter for July 1st were 5,346 packages, as against 2,276 for the same dap last week and 2,233 for the corresponding date a year ago, while the receipts today were nil as compared with 278 for the same day last week and 479 last year. At Gould's Cold Storage on Tuesday there were 800 packages creamery butter offered, which sold at 52½c per lb. f.o.b. country points, showing an advance of 2c per lb. as compared with the same day last week. There were no new developments in the market today, the feeling being firm, but the demand for round lots was somewhat limited and the volume of business small. The trade in a jobbing way was steady and prices were maintained with sales of finest creamery at 56c per lb. in 1-lb. blocks, and at 55c in solid packages.

We quote wholesale jobbing prices as follows:

Pasterized creamery	53c to 53½c
Finest creamery	52c to52½c
Fine creamery	51½c to 52c
Finest dairy	47c to 48c

The receipts for cheese for July 1st were 30,108 boxes, as compared with 26,104 for the same day last week, and 25,908 for the corresponding date a year ago, while the receipts today were nil as aginst 7,364 for the same day last week, and 9,695 last year. At Gould's Cold Storage on Tuesday the offerings amounted to 6,000 boxes, for which there was a steady demand from exporters and all sold at 29¾c per lb. f.o.b. country points, showing a decline of ¼c to ⅜c per lb. as compared with last week. A steady trade continues to be done over the cable, but on account of the limited amount of ocean freight space available of late the shipments have been light.

Peterboro, Ont. July 5.—There were 1,724 boxes of cheese boarded. Sales: 923 at 30½c; balance at 30 7/16c. A resolution was passed accepting Montreal weights.

New York, July 5.—Butter barely steadp. Receipts 19,721 tubs. Creamery, higher than extras, 59¼c to 51c; creamery, extras, 92 score, 49½c to 50c; firsts, 48c to 48¼c; packing stock current make, No. 2, 44½c to 45c. Cheese firm. Receipts, 5,417 boxes. State, whole milk, flats, current make, specials, 32c to 32½c; do., average run 31c to 31¾c; State, whole milk, twins, current make, specials, 31¾c to 32½c; do., average run, 30¾c to 31½c.

THE PROVISION MARKET

Montreal, July 5—The feature of the live hog trade today was the stronger feeling which developed in the market and prices scored an advance of 50c per 100 lbs. This was attributed to the renewed strength in the Toronto market and the fact that the offerings here today were not sufficient to satisfy the requirements of the trade. The demand from packers for selected lots was good and an active trade was done with sales at $23 per 100 lbs. weighed off cars, with a cut of $2 per 100 lbs. for light weights, $1 to $2 for heavies, $5 for sows, and $7 for stags. There was no change in the condition of the market for dressed hogs, but the undertone was very firm with a steady demand for small lots to meet immediate wants and sales of city abattoir fresh-killed stock were made in a wholesale jobbing way at $31 to

$31.50 per 100 lbs.

The condition of the market for smoked and cooked meats was unchanged, but the feeling is very firm in all lines on acocunt of the continued heavy demand for supplies for local consumption and for shipment to country points, consequently an active trade is passing in a wholesale jobing way and stocks on spot have been reduced to a low level. Sales of 8 to 10-lb. hams were made at 44c to 45c, 12 to 15 lbs at 42c to 43c, heavy weights at 40c to 41c, cottage hams at 41c, picnic hams at 32c to 34c, cooked hams at 64c, and cooked shoulders at 51c . Breakfast bacon sold at 46c to 56c. per lb., as to quality and brand, Windsor selected bacon at 50c and Windsor boneless bacon at 54c to 55c per lb.

There was no important change in the market for lard, prices being firmly maintained under an active demand from all sources for supplies and a large volume of business was done with cales of Canadian pure leaf grades at 38c to 38½ per lb. in 20-lb. wood pails, and at 39c to 39½ in 1-lb. blocks. The trade in sortening is also fairly active and prices are unchanged with sales at 31c to 32c per lb. in 20-lb. wood pails, and at 32c to 34c in 1-lb. blocks.

The receipts of provisions today were 11,633 packages lard, 2, boxes hams and bacon, and 1,954 packages tinned meats.

EGGS MORE ACTIVE AT FIRMER PRICES

Montreal, July 5.—The egg market gathered considerable strength as the week advanced, due to a falling off in receipts and a material advance in the British market, resulting in considerable export business for prompt shipment. Country track shippers reported marked improvement in the demand. They say they have been able to make sales from one to two cents in advance of the previous week. Production is reported to be declining and quality improving since the weather has become cooler. Storage space is very scarce. Only a few private operators who did not buy heavily early in the season have room in their coolers. They are taking a few off the market for storage purposes, in addition to their immediate trade requirements. Generally speaking, the outlook is much more healthy, and if the export demand continues a further advance in prices may be looked for. There is practically no change in the western situation beyond a further decline in British Columbia. Receipts are of poor quality and the country has not got back to normal in the handling of freight and express.

Several cars have been sold for export to Great Britain during the past week for prompt shipment and the market seems to be broadening. Most of these sales, it is understood, have been made on an f.o.b. basis, subject to buyer's risk from damage in transit. There is also reported to be considerable enquiry for fall shipment and some further business has resulted.

The receipts of eggs for July 1st were 2,019 cases, as against 2,184 for the same day last week and 1,452 for the corresponding date a year ago, while the receipts today were nil as compared with 1,235 cases for the same day last week and 1.053 last year. The total exports of Canadian eggs from March 1st 1919, to June 28th, 1919, were 37,628 cases, or 1,128,840 dozen. There was no change in local jobbing prices today, but the tone of the market is firmer with a fair trade passing in a jobbing way for domestic consumption.

We quote wholesale jobbing prices as follows:

Strictly new laid eggs.....00c to 54c
Selected stock.....00c to 52c
No. 1 stock.....00c to 48c
No. 2 stock.....40c to 42c

Receipts of live and fresh killed poultry were about the same as a week ago. In Western Ontario shippers diverted a large portion of their shipments to Buffalo, as that market was offering better prices than Toronto. Arrivals consist principally of old fowl, spring chickens, and cocks with a sprinkling of ducks.

Storage stocks are moving about the same and are now getting into very small compass. Prices have been slightly reduced on one or two varieties to meet the reduction in prices of fresh arrivals. Generally speaking, the poultry situations is in excellent shape.

The receipts of live and fresh killed poultry in the United States are increasing, particularly live, and prices are lower and easy.

Storage poultry stocks have been reduced in the States, it is said, to a point where it leaves the situation in a very healthy shape. Stocks, however, are still much in excess of these at the same date last year.

THE FARMER'S AUTO SERVICE

The Maritime Farmer's auto department is rapidly coming into favor; it is something in which every subscriber to this paper is vitally interested. We are prepared to help you with your auto troubles. Not only that but you learn from the experiences of others much concerning your own difficulties. The department is conducted by an expert, who is at your service.

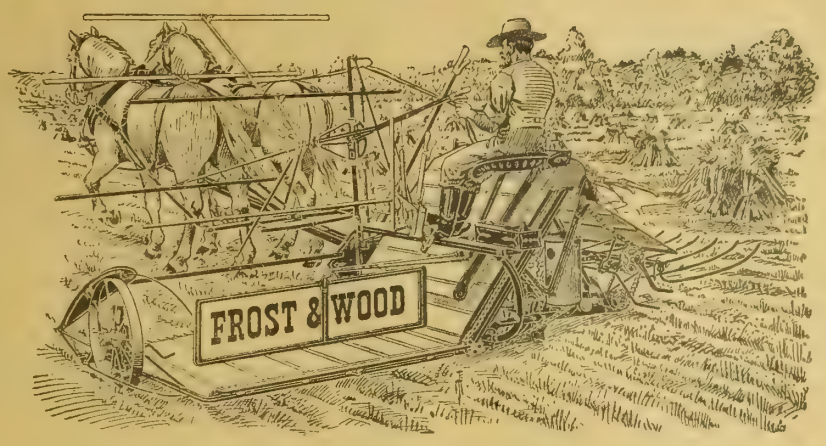
Then we can supply you with tires and inner tubes. If you are in need of them write us, that is, if you are a subscriber to this paper. We are not in the tire business but we are conducting a service for the benefit of our subscribers. If you are an auto owner and a subscriber to the Maritime Farmer, write us and we will be glad to advise you to your advantage.

The stones you throw at others today you will find in your pillow tonight.

Butchers in Birmingham, England, have undertaken to buy bones back after the housewife has made full use of them, paying the customer half of proceeds of their disposal. They are used for the extraction of glycerine and for the manufacture of phosphate for fertilizer and a valuable pig and poultry food.

FROST & WOOD BINDER

A Binder is a mighty important purchase. Let the example of thousands of satisfied and successful farmers who have bought Frost & Wood Binders influence you.



Light draft and fast, clean, easy work, guarantee more acres cut per day—the F. & W. Binder is the result of many years experience with Canadian conditions.

Remember, your PROFITS lies in the last few bushels

As in every other business, the bulk of your output goes to pay for labor and expense of all kinds which must be paid before you get your profit. This means that it is the bushels "at the end" that bring your net profits. Therefore, in justice to yourself, use a Binder that will harvest every possible head of grain —no matter what the crop is like, heavy or light, tangled or lodged or straight. That means just the one make—FROST & WOOD. It has the light draft, the big elevator capacity, the sure cutting and binding attachments, and the wide and easy reel adjustment that brings every possible straw to the knives.

The Frost & Wood is the Binder of the day. See it at our nearest Agent's or write for our Binder folder and you'll readily see why.

FEEDS FOR SEASON 1919-20

(Continued from page 969)

SANDS OF DOLLARS FOR THE FARMERS OF THE MARITIME PROVINCES LAST YEAR. WE EXPECT TO PERFORM A SIMILAR SERVICE IN 1919-20. If your society has not been organized for wholesale buying, get busy. Possibly you may have heard of how much some other society saved. We can place you in the same enviable position. AND REMEMBER WE WILL SELL YOU FEEDS THAT ARE SOLD ON THEIR ACTUAL CASH VALUE, MEASURED BY THE PROTEIN-FAT UNIT COST TEST. THAT IS HOW YOU SHOULD BUY FEED, HAVING IN MIND, OF COURSE, THE PALATABILITY OF THE GOODS. WE HAVE IN MIND BOTH DESIRABLE FEATURES. AND, MOREOVER, WE HAVE FAITH IN THE GOODS WE SELL, ALL OF WHICH ARE GUARANTEED TO BE AS REPRESENTED.

OBTAINING RESULTS WITH CANE AND BUSH FRUITS

(Pro. O. M. Taylor, Geneva, N.Y., at Ontario Fruit Growers' Assoc.)

Other things being equal, currants and gooseberries are at their best in cool, moist, retentive soil of rather heavy clay-loam type, quickly deteriorating in hot, dry, sandy soils. None of these fruits will thrive in wet soils, a soggy condition being especially favorable to winter injury of cane fruits. All soils should be well drained. There is but little danger of over-feeding bush fruits but heavy applications of nitrogen may at times cause excessive growth of cane fruits which do not fully mature, resulting in winter injury.

The pruning of cane and bush fruits is important. The old canes of raspberries and blackberries should be removed as soon as the crop has been harvested, thus destroying insects and diseases which may have infested the fruiting canes, and giving more room for the new growth. No further summer pruning is required with red raspberries. In the spring, the canes are cut back to a desired fruiting height. Summer pruning of black raspberies and blackberries depends on the method of culture. Usually the new growth is stopped at a desired height by pinching out the succulent tip. In the spring the lateral branches are shortened back, depending on the vigor. The vinelike growth of dewberries must be supoprted by stakes or trellis. In the Hudson Valley, where berries are grown intensively, stakes or various forms of trellis are in isommon use. but ini western New York the trellis seldom seen.

Systematic pruning of currants is essential to improve the fruit and to renew old and weak wood. Most of the wood over three years old should be cut out and only enough for the yearling wood left to maintain an annual supply of the younger wood, leaving from five to eight canes per bush. The tops of gooseberries should be thinned and occasionally cut back when necessary to encourage new growth. Varieties that sucker freely may be pruned much like currants.

Few, if any, growers spray the canefruits. As a rule, insects do not appear in injurious numbers in New York, although there may be occasional infestations of the snowy treecricket, the raspberry caneborer and the raspberry sawfly, only one of which may be controlled by spraying. Unfortunateiy, there are several fungus troubles or diseases which are difficult to control, such as anthracnose, orange rust, cane blight, crown gall and raspberry yellows. The most common insect enemy of the bush fruits is the currant worm and San Jose scale, which readily yield to proper spraying.

All efforts come to naguht with the selection of an inferior variety. Some varieties are almost cosmopolitan in

Cletrac
TANK-TYPE TRACTOR

Gets the Hay in Quickly

You don't want to take a lot of time to get your hay in. You don't want to take a chance on the weather. Let the Cletrac Tank-type Tractor do your haying.

A Cletrac Tractor will pull the mower at more than twice the speed of a horse. It will pull a hay-loader at an even, steady speed. *And no matter how hot the weather, it won't worry the Cletrac.*

Cletrac owners are finding that they can do twice the work with half the help. Economical, too, runs on kerosene (coal oil).

You can't beat the Cletrac for summer fallow. Plows fast—and and plows well—without ever packing the soil.

Later on you'll need its fine belt-power for threshing and silo-filling. See the Cletrac Tank-type Tractor now. There's a Cletrac dealer near you. Write him or us for our book written by farmers, "Our Owners Say."

Dear Sir,—

In reply to yours of the 31st ultimo, I have three tractors working in ploughing and preparing land for flax and other crops. They are as much superior to the wheeled tractor, which I used before, as a twenty-horse-power steam engine is over the old horse-power.

Our experience is that the plowing cost per acre for fuel and oil is around 25c. on an average of over 300 acres; the general average of a little over one acre per hour plowing, with three 12-inch bottoms, giving a perfect job.

We have found it delivered on the belt over 30 horse-power and is actually quicker to set and easier to tighten on the belt than any other rig we know of.

I have sold four teams of horses, which we used for this last year for about one quarter the acreage I will be running this Spring with two tractors.

Yours very truly,
(Signed) A. L. McCredie

adaptability but others are at their best only in restricted areas. The question of what to plant is difficult partly on acocunt of the great number of varieties available but more so because of the fact that under different environments and under unlike surroundings the same variety may change both in plant and fruit-habits. The best varieties in one place may be all but worthless elsewhere. Adaption should be determined before planting extensively.

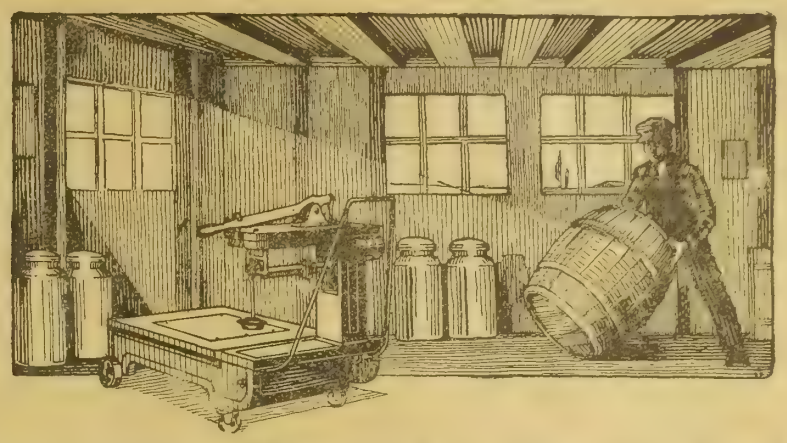
The testing of the newer, most promising kinds should be encouraged and every effort made to develop a plantation especially for home use of choice varieties, high in quality, of all the classes of both cane and bush fruits, including the red raspberry, black raspberry, yellow raspberry, purple raspberry, blackberry, dewberry, the red, white and black currant and especially some of the European varieties of gooseberries. When grown for home use, the fruits may be left on the bushes until the highest degree of flavor and quality has been developed—giving the grower a product tempting to the eye, and delighting all by the handsome appearance, delicate aroma and pleasing flavor. With the many varieties at our disposal, and with a better knowledge of their adaptabilities, intelligent effort cannot fail to suply our tables with fruit most acceptable to both sight and taste.

WHAT THE COW TESTING ASSOCIATION CAN DO

The cow testing association takes the guesswork out of dairying. No longer can the camoflage of a fine appearance protect the low-producing dairy cow. Confirmation indicates performance, but the Babcock test and the milk scales always tell the true story. Knowing the true feed and production records of each cow, the dairyman practices selective breeding, eliminates with certainty all low producers, and feeds the remainder according to known production.

WATER SUPPLY FOR DAIRY COWS

During the summer months especially during the dry time of the season, look well to the water supply for the cows. The water in ponds may become so low and of such poor quality that it is not fit for cows to drink, and the same may be true of running streams in the pasture, especially the small streams. Water furnished by ponds or streams is all right as long as it is clean, but it is difficult to keep it clean when the cows have free access to it, for they will wade and stand in it for its cooling effects and not only soil the water, but while in the water will switch their tails at flies and thus plaster themselves with a very bad sort of dirt, much of which may get into the pail while milking. Water from the wells is best for cows in summer and, if watered regularly at the well, they will come to it when they want a drink rather than drink dirty water in the pasture.



Fairbanks Portable Farm Scales

—the handy scales for the barn, the dairy, in the granary and the house.

These are the scales designed for the farmer and adapted to every use to which medium sized scales can be put. No detail which would make them the complete farm scales has been overlooked. Fairbanks Portable Farm Scales have a capacity of one ton in divisions of half pounds. They are equipped with a 26x34 inch platform, 11½ inches off the ground, with ball-bearing swivel casters, low weighing post, convenient handle, and bag rack for the weighing of vegetables. These compact and complete scales are a correct part of the equipment of every farm. Their accuracy is unquestioned.

Fairbanks Union Scales

are economical, convenient and accurate for household and store use. Capacity 240 pounds. Write today about scales for your farm or home.

BEDDING MATERIALS AND RELATIVE VALUES

There is much argument as to the relative value of the different kinds stockmen seem to think that wheat straw will go further than oat straw of bedding amterial for stock. Most for this purpose, and it has been commonly believed that shavings and sawdust will go much further than either kind of straw.

A test of different kinds of bedding materials at the Illinois Experiment Station, conducted in the spring of 1917, had interesting results. It was conducted primarily for the purpose of determining what kind of bedding material is most economical to use at the experiment station. A test of the water-holding capacities of the materials showed that when soaked for 24 hours oat straw retained about 19 per cent. more water than wheat straw, and twice as much as ordinary mixed shavings.

From this it would be expected that more shavings than wheat straw and more wheat straw than oat straw would be required to keep animals bedded. Such proved to be the case. With comparable lots of beef cows, dairy cows, and brood mares, 40 to 82 per cent. more shavings than oat straw and 9 to 18 per cent. more wheat straw than out straw was used.

From the standpoint of fertility value of the manure oat straw is somewhat better than wheat straw, and either kind of straw considerably better than shavings. The amount of animal excreta saved in the test with each kind of bedding was just about the same but the straw in straw-bedded manure is considered to have as much fertility value, pound for pound, as manure, while shavings have little or no value. They are so much inert material.

The amount of bedidng required and the fertilizer value of the manure saved are, of course, not the only criteria of the value of a bedding material. On an ordinary farm they are most important, but under some conditions the cleanliness of the animals is the first consideration, and under some the freedom of the bedding material from weeds seeds is an important factor. It is here that shavnigs and wheat straw have an advantage. Shavings kept the animals, especially cattle, noticeably cleaner than either wheat straw or oat straw. Wheat straw was somewhat better than oat straw in this respect. Shavings again have an advantage in being entirely free from weed seeds. Straw, and especially oat straw, may be a carrier of a variety of weeds.

Sizing up the whole situation, the bedding materials rank oat straw, wheat straw, and shavings in economy of amount required to keep animals bedded, and in the value of the manure produced, but the rank is just the reverse in efficiacy in keeping the animals clean and in freedom from weed seed.—J. W. Whisenand.

When the haying season has started, a very important task is under way, which means steady and careful work until the finish, or there will be a big loss, therefore everything pertaining to the hay crop should be put into the best possible condition beforehand.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The aderess must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on, as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue which will always be found on the editorial page of the proceeding issle. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. MARITIME FARMER, Sussex N. B.

FOR SALE—One pure bred Holstein Bull, dropped last August, two more dropped in January, good stock.—W. G. CAMPBELL, Salisbury, N. B.

LADIES WANTED to do plain and light sewing at home, whole or spare time, good pay, work sent any distance, charges paid. Send stamp for particulars. NATIONAL MANUFACTURING, COMPANY, Dept. A, Montreal.

CROCODILE WRENCHES—One of the most useful tools on the farm. Cuts a thread in three sizes, will hold a pipe or turn a nut. While they last, sixty cents each. Made of chilled steel. We pay postage.—THE MARITIME FARMER, Sussex, N. B.

GREAT WHITE LIGHT BURNERS—The lamp burner that doubles the light you get from your oil lamps. We have a few dozen to offer at 18c each, postpaid. They are a big investment for any person using oil lamps. In large size only. —THE MARITIME FARMER, Sussex, N. B.

THREE HUNDRED KEGS first quality wire nails, mixed sizes, suitable for repair work around farm buildings and other premiscs. Price $3.50 per 100 lbs. Apply by mail to "NAILS," care of Office Maritime Farmer, Sussex, N. B.

FOR SALE—Four very highly bred Guernsey bulls, one 20 months, two 6 months, one 3 months; also five heifers, 6 months. Dams cost $295, $275, $265, $175 and $150. Three have high records. Prices and full particulars from J. MILLIGAN & SONS, Kings Head, N. S.

WRITE ME for new Price List of Wire Fences, Gates and many other useful lines. I have taken over the business of The Page Wire Fence Co. in these Provinces and will keep for prompt delivery, a large stock of everything. W. C. ROTHWELL, No. 11 Water St., St. John, N. B.

POULTRY FOR SALE !

15 White Wyandottes, 6 S. C. Brown Leghorns, and 15 Utility Barred Plymouth Rock hens. $2.00 and $3.00 each. These will make the best of breeders for next season. Orders booked now for cockerels and pullets to be delivered in August and September. Prices $2.00 to $5.00 each. Special rates on mated pairs, trios or breeding pens. Satisfaction guaranteed. KEEP

Holstein-Friesian Cows

1. The Holstein-Friesian is a large vigorous cow, full of energy and abounding in vitality.
2. Her physical organization and digestive capacity are such that she is able to turn to the best advantage the roughage of the farm, converting the same into merchantable products.
3. She yields large quantities of most excellent milk, fit for all uses and especially suited for shipping purposes.
4. Heredity is so firmly established through her long lineage that she is able to perpetuate herself for the production of strong, healthy calves.
5. When for any reason her usefulness in the dairy is at an end, she fattens readily and makes excellent beef.

If you can't buy a herd, buy a heifer

WALLACE MACHINE WORKS REORGANIZED

Home of Sussex Little Giant Threshers Ready for Largely Increased Production to Meet Demands.

A business deal of interest in the Maritime Provinces was recently effected, when the Wallace Machine Works acquired control of the agricultural implement business of the Sussex Manufacturing Co. Limited, Sussex, N. B. The head of the new firm, Mr. H. W. Wallace, was formerly manager for the Sussex Mfg. Co. Mr. Wallace is a young man, a worker and a hustler. He has completely re-organized the business of which he is now the head. This has enabled the firm to prepare to handle the largely increased business which is now offering for the well known Sussex Little Giant Thresher. The orders received this year are in advance of anything experienced in the history of the firm, but the business growth will be readily handled. The Wallace Machine Works will also manufacture the other well known line which have been in their factory for years. The business announcements of this enterprising firm will appear in the Maritime Farmer from time to time and should be read carefully. They will carry an interesting message from a firm prepared to guarantee its output and stand behind that guarantee.

Fertility in the soil can be aptly compared to one's checking account in a bank. It is always easier to draw out than to put back. This is true of the growing of crops and of the fertilizing of the soil.

Red Clover and Its Impurities

Importance of the Clover Crop

From the standpoint of maintaining soil fertility there is no more important crop than red clover in those parts of Canada where it may be successfully grown. It is unexcelled as a forage plant and has great value as a soil renovater. By the proper use of clover in rotations it is possible permanently to maintain the supply of nitrogen in the soil. The value of clovers and other leguminous plants as soil improvers is due to their ability to use the free nitrogen of the air through the agency of bacteria living in the little tubercules on their roots.

Canadian-Grown Red Clover Seed

Success in clover gorwing is much more certain if Canadian-grown seed is used. Imported seed, especialy from a southern country, is likely to have been produced by varieties too tender for the Canadian winter. When Canadian-grown seed is used the risk of losing part of the crop from winter-killing is very much less than with imported seed.

One factor that discourages the production and use of Canadian-grown seed is that so much of iti has high seed is that so much of it has high a great extent, is due to the fact that the area of cultivated land per agricultural worker in Canada is very high.

It is quite possible, however, to improve the purity of our seed without materially increasing the labor applied to its production if correct principles are understood and aplied.

Weed seeds lower the value of seed by making it necessary to waste so much of the clover seed to remove them. Some weed seeds are about the same size as the smaller clover seeds and to take them out, much small seed must be wasted. Other weeds have seeds the size of the larger clover seeds. To eliminate these, much of the plumpest and best clover seed must be sacrificed. If No. 1 seed is selling at $12 a bushel, a rejected sample that must be reduced by one half to Make it No. 1 will be worth much less than $6, as the time, labor, power, etc., to clean it must be taken into consideration as well as the dockage. Indeed, few rejected samples be cleaned to No. 1. If, after reducing a lot of seed by 1/3 or ½, it will grade only No. 3, its original value must be uiqte low since this grade is in small demand and consequently sells at a price considerably below that for No. 1. Some lots of rejected seed cannot be made saleable by any amount of cleaning. Clover that will yield such seed should never be left for seed.

The weeds that cause trouble in clover seed production are not, as a rule, those which are seriously injurious to ordinary crops, and for this reason farmers are not in the habit of giving them much attention. Most of them are weeds that grow up from seeds during the summer, mature seeds in the fall about the time clover seed ripens, and then die. A few live two or three or more years. They make a start during the year the clover is seeded, live through the winter and are ready to produce seeds the next year, and in many cases every subseuenqt year until the field is broken up and the plants destroyed.

Two classes of weeds are injurious in growing clover seed. The first are those whose seeds are in the soil ready to grow if the clover fails to make a good stand. In spots where the clover has been killed out or makes a thin stand, they will grow and produce seeds to pollute the clover seed crop. An even, vigorous stand of clover throughout, either smothers out this class of weeds or prevents their seeds from germinating.

There is another class of weeds, however, which are able to compete more or less successfully with the clover plants and therefore occur wherever they have been introduced and allowed to spread. A good stand of clover tends to hold them in check, but not to the same extent that it does those of the first class. Once introduced into a field, weeds of this second class grow in the clover seed crop until they have been destroyed by proper cultivation and crop rotation.

Weeds of the second class include ribgrass, night-flowering catchfly, wild carrot, and black medick.

To prevent weeds from maturing seeds in clover seed crops the following precautions must be taken:—

1. Eradicate ribgrass, catchfly, black medick and wild carrot before the clover is seeded.

2. An even, vigorous stand of the clover seed crop will down greene foxtail, plantain, lamb's quarters, ragweed, docks, etc.

There are always plenty of seeds in the soil ready to produce weeds to occupy space where through any cause cultivated plants fail to make a good stand.

3. If the first crop of clover is taken for hay, cut it as early as possible. If this is done, the second crop is not only able to get a good start towards producing such a stand as will keep the weeds in check but it is ready to be cut for seed before some of the weeds are sufficiently matured to cause trouble.

4. Weedy patches should be cut green or if allowed to mature, should not be raked up and included with the crop drawn in and threshed for seed. Wherever the clover fails, weeds usually grow profusely and it is these spots in a field that often contribute largely towards the impurities found in the threshed seed.

Weed Eradication

To combat weeds one should know their life histories, that is, how they are propagated, the nature of their rootsystems, when their seeds mature, how long they live, etc. Each weed has its own way of winning in its struggle with the farmer's crops, and its habits must be learned in order to know how to get the better of it.

In studying the life history of weeds they are usually considered in groups or classes according to the length of time they live: as annuals, biennials and perennials.

Annuals.—Examples, green foxtail, ragweed.

Annual weeds complete their entire life history in one year. The seeds produced during the late summer or autumn lie dormant in the soil over winter and germinate in spring, blossom, mature their seeds and then die, root and all. Some plants that complete their life-cycle in a year are known as winter annuals; ;the seeds that have matured during the summer germinate in the fall, make a certain growth before winter sets in, complete their development and mature their seeds the next summer.

Annuals may be eradicated from land, however badly infested it may be, through any method by which germination is hastened and the young plants destroyed before they produce seed. The weeds of this class that give trouble in clover seed crops are those whose seeds ripen in the fall, at the time red clover seed matures. They make little growth in the early summer, shooting up unmolested after harvest when other farm work is so pressing, and producing seeds that are returned to the soil to lie dormant until conditions are favorable for their growth a year or more in the future.

To reduce the number of these weed seeds in the soil bare stubbles should have surface cultivation directly after harvest to prevent the further ripening of seed as soon as the grain crop is removed, and to encourage the germination of seeds already in the soil. The young plants that start from the seeds brought to the surface by cultivation may be killed by the harrow or ploughed under. In hoed crops, tillage should be continued late, as it is the plants that bloom and fruit after cultivation has ceased which are most likely to polute the land. The hoe should be used to destroy the late plants after cultivation of the crops becomes impracticable. Any practice that will prevent an annual weed from seeding will reduce and ultimately eradicate it. Fields seeded to clover should be clipped with a mowing machine a few weeks after the nurse crop is harvested to prevent the seeding of autumn weeds.

Biennials.—Example, wild carrot.

Biennials require two seasons to complete their growth, the first being spent in collecting and storing up a supply of nourishment, which is used the second season in producing flowers and seeds. Biennials must be either cut or ploughed down before they flower. Mowing at short intervals in the second year, so as to prevent the development of new seeds will clear the land of this class of plants; but a single mowing will only induce them to send out lateral branches, which, if not cut, will mature many seeds. Where ploughing is impracticable, such plants should be cut off below the crown of the root.

Perennials—Examples, Canada thistle, ribgrass, docks, sheep sorrel, plantain.

Perennials are plants that live for many years. They are propagated in several ways, but all produce seeds. Annuals and biennials, which live only for one or two years and are reproduced only by seeds, may be eradicated by preventinfi them from maturing their seeds, but in combating perennials it is necessary to destroy the plant. On account of the variety of life habits of the plants belonging to this class, no general treatment for their eradication can be given except that fields in which they are prevalent must be broken up and worked under a crop rotation that provides opportunities of attacking the weeds when they are most easily injured. Methods of eradicating the different weeds belonging to this class are outlined in circulars describing individual weeds.

The Red Clover Plant and its Culture

Botanical description.—Red Clover is mainly biennial. The year the seed germinates, only short leaves and stems are produced and no flowers. The second year the flowers are developed and the seed formed, and after ripening the seed the plant dies. As with most biennial plants, the root is a tarpot; that is, the single main root gradually tapers downward and produces numerous side branches. On these are developed the small, rounded or egg-shaped nodules which contain the bacteria necessary for the proper development of the plant. From the upper end of the tarpot, which is somewhat enlarged and generally known as the crown, are formed more or less numerous buds which develop into leafy stems. These as a rule are from one-half or two feet high, strictly upright or ascending from a decumbent base, the latter being the normal growth of stems developed from the outer margin of the crown. The stems are generally branched above the middle and the leaves are single at each joint. The three leaflets of which each leaf consists are oblong or egg-shaped and usually marked with a white spot of varying size and shape.

Biology of flower.—If Red Clover is isolated during flowering time, so that no insect can visit the blooms, no seeds will be formed, as it depends upon insects to transport the pollen from one flower to another. Bumble bees. which visit the flowers in order to secure the nectar, are especially active in this transportation. As the insect travels from one plant to another, carrying pollen from different individuals, the pistils of one are apt to be fertilized by pollen from another. Such cross-fertilization, in

fact, must take place before seed can be developed.

Cultural conditions.—Being a resident of the temperate zone, Red Clover succeeds best where the summers are not too hot nor the winters too severe. Although the roots go rather deep, the plant is injured by long and continuous drought. It needs sufficient rain during the growing period to enable it to flourish during the whole season. As Red Clover is rather cosmopolitian, a great number of varieties, adapted to different climates, have been developed. The suitability of a variety for a northern climate like that of Canada depends to a great extent upon its hardiness. Chilean Red Clover or other varieties originating in countries with a mild climate are invariably killeed by the Canadian winter, except in the southern parts of the country. It is, therefore, important to secure seed of northern origin. If possible, Canadian-grown should be obtained because as a rule home-grown seed gives the best results.

Soil.—Red Clover can be successfully grown on many kinds of soil, the most suitable being clay loams with a certain amount of lime and plenty of organic matter. Sandy loams also give good returns, especially on limestone foundation; but generally speaking, Red Clover prefers the heavier soils. It can be grown even on stiff clay, provided the subsoil is open. For its proper development Red Clover, like Alfalfa, depends a good deal upon the subsoil. This must be open and well-drained. Stagnant water near or on the surface is decidedly injurious. Water-soaked soil excludes the air necessary for the respiration of the roots and is in a bad physical condition to meet the alternate thawing and freezing of early spring. As is well known, water expands when changing into ice, and if the surface soil contains an abundance of water it will consequently expand when freezing. The overground parts of the plants will be lifted up with the freezing soil. As the lower roots are anchored in the subsoil and therefore unable to follow the upward move- they will be stretched and broken. The disastrous ...rnate thawing and freez- ... evident that one of the first ... tions of successful clover growing is well-drained soil.

Habits of growth.—Being a biennial, Red Clover devotes the first season's growth to the development of its root system and the accumulation of strength to meet the winter's hardships. It therefore produces a strong tap root, which, if soil and weather are favourable, penetrates to a considerable depth. The overground parts of the plants consist at first of only a few short, upright stems which carry leaves but no flowers. Later in the season, short leafy shoots are developed which generally lie flat on the ground and are known as the winter tuft. At the same time the tap root begins to contract until its original length is reduced by more than ten per cent. As the end of the root is firmly anchored in the ground, the result is that the overground parts of the plant are pulled down. This process, which has been observed in other plants such as carrots and parsnips, is evidently meant to bring the stems and leaves into close contact with the ground where they are best protected against frost and wind. Early in the spring of the second year, the branches of the winter tuft develop into flower-bearing stems, which, if not cut or pastured, produce seed and late in the fall die. The great mass of clover plants are thus biennial. Red Clover types exist, however, which show a decided tendency to live longer, especially if the plants are kept from seeding by continual cutting or pasturing.

Seed.—Except in southwestern Ontario, Red Clover seed is only grown to a very limited extent in Canada. The Maritime Provinces have been producing small quantities in certain localities during the past three or four years. Whether or not a field should be used for seed production depends on conditions. If these are favourable, all or certain parts of the field are commonly left for seed. Success depends on many factors. If the latter part of the summer, when the seed is ripening, is rainy, there is far less chance of producing good seed than if the weather is warm and dry. Cold, stiff soils, which may produce luxuriant growth, are not as a rule satisfactory for seed production. The best soils are sandy loams with an abundance of lime and a fair supply of potash and phosphates. A thick stand of clover improves the quality of the hay but produces only a scant amount of seed. A relatively thin crop will give a heavier yield and the seed produced is of a better quality. A smaller amount should therefore be sown for seed production than for hay or pasture.

Red Clover should be cut for seed when most of the heads have turned brown and the stems begin to dry up. The seeds in most of the heads are then ripe and of a pronounced color. By cutting earlier, a large proportion of the seeds will be immature and shrunken, the vitality will be low and the general colour and appearance inferior. It can be cut with an ordinary mowing machine. The heads and flowers are easily broken by careless handling, especially in dry, hot weather. Threshing should be done in cold, dry weather as it is difficult to seeds from the pods when it is damp.

Quality of seed.—The colour of ordinary commercial Red Clover seed is mixed, some seeds being yellow, others purple, and others bright in one end and dark in the other. In some samples the bright colours prevail while in others the dark seeds are most common. It is a popular belief that bright coloured seeds are not fully mature and that samples which contain a large proportion of them are inferior. This, however, is an error. All seeds gathered from any individual plant are of the same general colour. In some plants all the seeds are yellow, in others deep violet and in others uniformly two-coloured. Bright yellow seeds are just as ripe as dark purple ones. The mixed colour of the ordinary commercial sample therefore does not mean that the seeds are not uniformly ripe. It simply means that it is composed of seeds of different types, each type having its own colour. Although the darker seeds are more popular, the colour should not be taken as an index of value as the most desirable plant types may have pale yellow seeds. Good red clover seed should have a shiny lustre and contain only a small portion of undeveloped, shrunken seeds. The legal weight is sixty pounds per bushel.

The seeds of many of the weeds that grow in red clover and ripen at the same time are of such size that they are difficult or impossible to remove by sieves in an ordinary fanning mill. Few fanning mills are fully equipped with siever for cleaning small seeds; indeed, most of them are not designed for this work. However, seed that contains a very large number of small weed seeds or that contains only a few more weed seeds than are permitted in seed that may be legally sold under the Seed Control Act may often be cleaned to grade without heavy dockage, provided the proper sieve is available.

If there is a properly equipped and operated power cleaner within a reasonable distance it will usually pay to have seed cleaned by it.

For cleaning small quantities, hand sieves may be found to be most satisfactory and economical.

A sample usually contains few weed seeds larger than the clover seed. Ragweed if none of the outer hulls has been removed in threshing, should be separated from the clover by a 1/15-inch perforated zinc riddle. Sticks, pieces of straw and anything larger than the clover run over this sieve.

A long mesh woven wire screen is better than one made of square mesh wire cloth for cleaning red clover seed. The 2 by 24 is often employed for this purpose, but the exact mesh required will depend on the size of the clover seed and the kind of impurities to be removed. A long mesh sieve will hold all the good clover, allowing the smaller impurities to apss through. This sieve, assisted by the air blast, should take out practically all of the pale plantain, much of the mayweed and lamb's quarters, and many of the ribgrass as well as shrunken clover seeds. Besides the 4 by 24 sieve, the 4 by 25, 4 by 26, 4 by 28, 6 by 28, etc., are also recommended as lower sieves for cleaning red clover, their efficiency depending upon the size of the seeds composing the sample.

The 22 by 22 woven wire screen is very useful in the lower shoe for taking out sheep sorrel and seeds only slightly smaller than the clover. In some cases the 20 by 20 or 18 by 18 may be required, but this will allow considerable of the smaller clover to pass through.

Hulled ragweed, docks, catchfly, foxtail and black medick are very nearly the size of clover and are impossible to remove by means of an ordinary fanning mill. Fields must be cleaned of these weeds before clover seed can be grown with profit.

REWARDS FOR OFFICERS AND SOLDIERS

For Services in the Field, and for Services rendered in captivity, or in Escaping or Attempting to Escape therefrom

1. Recommendations for reward for services in the field unconnected with capture and rendered prior to 15th November 1919, may now be submitted; and if the individual recommended was captured in subsequent operations, the fact must be stated.

2. Restrictions whereby recommendations in respect of services connected with capture could be considered if such services were rendered prior to 15th July, 1918, have been removed. Such services will now be considered irrespective of date, provided that, in the matter of capture, the individual has been absolved from blame by competent authority.

3. The following srevices are eligible for such forms of reward as may be considered appropriate, provided that no blame has been attached to the individual in respect of original capture:

(a) Exceptional services rendered by officers and soldiers whilst prisoners of war or interned.

(b) Exceptionally gallant conduct or determination displayed by officers and soldiers in escaping or attempting to escape from captivity.

When merited services of this nature will be eligible for such "gallantry" distinctions as normally reserved for "services under fire."

4. The facts supporting each recommendation must be substantiated by statements of evidence from at least two witnesses, who have first-hand knowledge of the circumstances of the case; and, except under para 3 (b) above, one of the witnesses must be an officer.

5. Each statement of evidence supporting a recommendation must be made out in the handwriting of the witness who signs it. A single statement signed by two or more witnesses will not be accepted.

6. Recommendations will not be accepted unless they reach Militia Headquarters by 31st August, 1919.

For officers and soldiers who are serving, they will be submitted through the usual official channels.

For officers and soldiers who have been demobilized, they will be forwarded through the District Officer Commanding, in whose command they are resident.

In forwarding recommendations, District Officers Commanding will add such comments as they think appropriate.

Forms of recommendation may be obtained at Militia Headquarters, M. D., No. 7, St. John, N. B.

MEETING OF THE N. B. CHEESE AND BUTTER BOARD

The regular semi-monthly meeting of the New Brunswick Cheese and Butter Board was held in the Agricultural School Building on Wednesday afternoon, the 9th inst. Representatives from the different factories were present and the buyers on hand were R. B. Colwell, Halifax; Mr. Stubbs, representing H. W. Cole & Co. and Mr. Bonnell, Harris Abattoir Co.

The cheese boarded were as follows:

Factories	No. cheese
Havelock	50
Lower Ridge	50
Cornhill Corner	65
Cornhill	125
Newtown	48
Killam's Mills	50
Lewis Mountain	50
Mannhurst	50
Mt. Middleton	25
Carsonville	55
Hd. of Millstream	100
Berwick	50
Collina	60
Pearsonville	50
Belleisle	65
Hammond	60
Clover Hill	25
Penobsquis	25
Total	1003

The price offered by the buyers did not come up to the expectations of the salesmen and of the above only 165 cheese sold on Board at highest price offered, 28.2. Several important points came up for discussion before the Board.

One of the buyers, Mr. Colwell, of Halifax, said that cheese from New Brunswick was invariably short in weight, averaging one pound or more. He felt that the scales at the factories should be inspected and this evil remedied. Attention was also called to the fact that water proof covers should be kept on hand by factories to cover cheese which is being moved from factories to railways for shipment in wet weather.

The next Board meeting will be held on July 23rd.

CROP REPORT

The cutting of hay has become quite general in Carleton County. The crop is generally below the average. The cold dry weather of June, accompanied by several frosts, was responsible for the lack of growth. In the northern counties reports indicate a very poor hay crop. Some reports state that old weadows are hardly worth curring. In the eastern section, the crop is later and will be helped some by recent rains. In the southern counties and York the crop varies from average to poor, according to whether the meadow is new or old.

Grain Crops generally have a good color and promise well at present. With a few good rains when the crop is heading and filling, there should be a good average crop. Pastures are good and recent rains will hold them for a time longer.

Cattle are generally in good condition.

The season for the berry crop has been lengthened by the rains. Prices have advanced considerably during the past week.

The shoes should be removed as soon as field work begins. There is no earthly reason for shoes on a horse with sound feet, while he is working in the field. A horse that is used for driving to town may be kept shod.—Geo. F. Glover.

The soils most benefited by wood ashes are light, sandy, and gravelly loams and mucks and peaty soils.

Gleanings From the N. S. Agricultural College

SEASONABLE HINTS

Don't let the hoe get rusty. Whether it be of the hand variety or the horse cultivator it should be kept moving at every opportunity. It destroys weeds, conserves moisture, and sets free elements of fertility in the soil which otherwise would not be available to the growing plant. Experiments have proven that a surprising percentage of increase in crop results from each trip of the cultivator.

DAIRY NOTES

We are now coming to the crest of the wave for the year in Dairy products. The hot weather is on and a great deal depends on the manner in which cream is kept. The creameries are having a big season and the bulk of butter now made goes into cold storage. Creamery men have more difficulty in getting sweet cream now than at any other season. The creamery patron is directly affected also by the treatment he gives his cream. There is bound to be a considerable variation in the July tests on account of delays in delivery or carelessness in handling. If the cream is kept cool and delivered sweet the variation will be slight.

All our creamery managers are glad to give any assistance they can in the way of advice and otherwise. It is in their own interest to do so, and in many instances conditions can be much improved with little or no increase of labour or expense. The price of butter fat was never nearly as high as this year for the month of July, and the consumer who pays will expect, and has a right to expect, that what he buys at such prices will be of the finest possible quality. The whole matter is summed up in a word:—Keep the cream clean and cool and do not delay delivery.

Many different means are in use for simplifying the work of caring for cream. Where natural conveniences are not at hand the most practical of these is the insulated tank. Plans of this device, or any information desired may be obtained from any creamery manager or from the Dept. of Agriculture, Truro.

STUDENT PROSPECTS

Applications have begun to come in to the Agricultural office from students who expect to join the classes in Agriculture next November. There never has been a time when the profession of farming offered such opportunities as the present. It is not to be expected that many students will take up the general courses unless it is their intention to farm. But the man who wants to farm needs scientific education now more than ever, and to have it pays better than ever. The difference between good and poor farm practice is accentuated by the higher scale of prices, and the enlarged vision which technical training gives a man opens doors of opportunity which he never before dreamed of. The Province of Nova Scotia, and the Maritime Provinces generally, have at Truro an institution of which they may well be proud. It is not merely a school of farming; it is also a College where the highest ideals of citizenship are stimulated. The attendance this year should be larger than ever.

A GOOD TRACTOR TEST

The management of the Horticultural Division at the College have recently been clearing a tract of land, which had never been plowed, and was heavily overgrown with small birch, Laurel and blueberry. A tractor drawing a western breaking plow was tried out. The College authorities are most enthusiastic over the results. The land was hillocky, and the growth very tough, presenting a pretty hard proposition. The growth was completely turned under, and a splendid seed bed formed with half the labour usually required for breaking such land.

THE POULTRY PEN

Now is the time to weed out the poultry flock. The old hens must be disposed of without sentiment or pity. They will lay few eggs after this, and will probably spend the major part of the summer occupying nests that should be better used, and doing their best to spoil the good work of younger fowls. Kill and eat or market every hen that is two years old or more, unless there is very special reason to keep her for breeding purposes, and even that is a doubtful measure.

Swat the rooster! In olden days, before the invention of the clock, he had an important function as a kind of town crier to tell the time, and ancient literature has frequent references to the time of the cock-crowing. The modern world has no need of him for that purpose. It has much more reliable and musical means to awaken us to the new day. His crow is all he has to offer for his feed from this time forth until next Spring, and it is not worth it. The hens lay just as well—indeed experiments have shown that they do better—without his attentions. The infertile egg is the only one that is fit for market or even for food at home in warm weather. It is a well-known and a somewhat inappetizing fact that a few hours of warmth produce an amazing development of the life germ. A general rule is that the fertile egg becomes unfit for eating purposes almost as quickly as milk, if lying in a warm place, while infertile eggs have been used and betrayed no taint after 14 days in an incubator at 103 to 104 degrees. In other words the keeping qualities of fertile and infertile eggs is as 24 hours to at least two weeks.

Kill, sell, or confine all mature male birds as soon as the breeding season is over. "Swat the rooster!"

The idea is common that the cellar is the place to keep cream while ripening. It is in many cases a mistaken idea. Unless the cellar is perfectly ventilated and free from all roots and vegetables there is almost sure to be a taint on the cream. In the matter of cooling, cream left in the open air will cool very slowly. When taken from the separator it should be immediately placed in cold water. If our memory is correct it takes just about seven times as long to cool off any warm substance or liquid in the open air at, say, 40 degrees fah., than it does in water at an equal temperature.

The egg-laying contest announced by the Poultry Division, N. S. Dept. of Agriculture, is getting well under way. Quite a number of entries have already been made. The top limit is thirty pens, and any one wishing to make entry should do so at once and avoid disappointment. The management wish to make it clear that this is not essentially a test of breeds, although that may incidentally come into prominence when results are given out. The central dea is to stimulate a higher production per hen than now obtains in most quarters.

When spraying for bugs, spray also for blight and kill the two great foes of the potato crop with one does. Any arsenical poison may be mixed with Bordeaux mixture to accomplish the double function. By the way, persuade your dealer that you are not anxious to pay three times as much for a green poison than for a white one that does the work better. The cheapest buy poison at present is arsenate of lime, and it is being manufactured in enormous quantities now on account of its efficacy against the boll weevil, the foe of the cotton grower. If you cannot get it this year, however, use what is at hand.

While the number of those who manufacture butter at home is much less than it was years ago home made butter is still a considerable item, and when it can be obtained of good flavour and quality is preferred by many consumers to the creamery product. There is a surplus of Dairy butter at this time of the year also, and it must be made with the expectation of keeping until winter. This is not at all a difficult matter. Butter that ies carefully made and put down will turn out in equally good order whether used next week or next winter.

Cream kept in stone crocks or wooden churns while ripening is almost sure to convey a tainted flavour to the butter. The writer has again and again been victimized in greater or less degree by good looking and cleanly made butter, which at first had only a faint flavour of the receptacles in which the cream had been kept, but which rapidly deteriorated in quality until unfit for table use. In hot weather it is particularly necessary to exercise care in this matter. To get best results, and it will pay in the long run, keep the cream in clean tin dishes large enough to hold a complete churning. Keep it cool and well stirred. Do not add fresh cream to the old until thoroughly cool. The quality of the finished product, apart from this question of the kind of dish to use, will be largely determined by the treatment the milk and cream receive during the first half hour.

Why Not Name the Farm

It is rather unfortunate that more farmers in Maritime Canada have not adopted names for their farms. The average farm is usually referred to in some such way as Lot 21, Cincession 3, Township of A——, a description which, to say the least, is a perfectly definite and accurate way of locating it; but the question naturally arises, does it give any touch of "individuality" or "personality" to it? Does it bring out any feature which serves to distinguish the farm from lot 20 or lot 22 adjoining? Evidently not! The only way of giving the farm individuality is to name it. The ramshackle summer cottage is deemed worthy of a name, while the city resident often sports a name plate bearing some such inscription as "Inglewood," even though the owner himself is the only person who can explain the adaptability of the name to the house, or the house to the name. If such are worthy of special names, does not the farm merit one as well?

What's in a Name?

To use a military term, it might be said that giving a name to a farm improves the "morale" of the staff. The moment that "Riverside Farm" is painted on the end of the new barn, or appears on a nameplate at the front gate, automatically a sort of responsibility is placed upon all hands to keep things looking just a little bit better than before. The fact that the attention of the passerby has been directed to the farm an account of its name invites an effort on the part of every member of the farmer's family to keep everything looking spick and span. To have the name "Riverside Farm" connected with a poorly tended lawn, a dingy unpainted barn, a muddy lane, straggling fences, a weedy garden, or a shabby looking farm home is not a very welcome idea to the owner and his family, and they will be prepared to do everything possible to prevent such an impression from getting abroad. This brings to light one way in which the farm name claims value on a cash basis, as well as merely catering to sentiment. A farm where the buildings and equipment are in good repair is of more value and brings a higher price on the market than a place in bad repair. Giving the farm a name adds interest to the sort of humdrum task of keeping repair work promptly looked after, and hence adds value to the farm.

An Advertising Scheme

Naming the farm is a pood stroke of business for any farmer, no matter what his particular line may be. The breeder of pure bred stock, however, has a much better chance of reaping benefits from the use of a farm name, than a farmer who is not specializing along any particular line. He has the chance to turn it to good advantage as an advertising dodge—one which though it costs him nothing to carry on, keeps his name before the public, and in all likelihood, long after he has handed over the reins to more youthful hands, and exchanged the worries of business, for slippers and the easy chair. We refer to the plan of working the farm name into the pedigrees of live stock, born and reared on the farm. In the natural course of events representative animals from the farm herd will find their way into the stables of various stock farms here and there throughout the country. Some of them, if they fall into the right hands, will probably win honors in the show ring, others may perhaps come to the fore as efficient milk and butter producers. One thing certain, whatever may happen them, wherever they may go, they will reflect one way or the other on the farm they came from, and the breeder who bred and developed them, adding to or detracting from his reputation just according to their deeds.

The advertising feature of the farm name may be exploited in a rather more direct way than the one mentioned above. Letterhead stationery bearing the name of the farmer, and some sort of a business add outlining the sort of stock he may have for sale, along with perhaps an engraving of some exceptionally fine animal may be used. Then, too, if his banker is of the accommodating sort with an eye open for good business, he will supply him with prifate cheques with his name printed on them. Better still he might be persuaded to make up a special cheque carrying the name of the farm. The banker would not be in the least reluctant about doing this for a good customer, and in assisting his farmer customer to adpertise he would also be doing his bank a good turn.

THE MARITIME FARMER

And Co-operative Dairyman
Registered Trade Mark
Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definite order for discontinuance is given,

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsible advertisers. To take advantage of this guarantee, written complaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said:—"I saw" your adv. in the MARITIME FARMER.

RATES FOR CASUAL ADVERTISEMENTS.
Contract rates on application.
Address letters and make all checks, money orders, postal notes, etc., payable to

THE MARITIME PUBLISHING CO. or
R. D. Robinson Publishing Co., Limited
Sussex, N. B.

NOTICE TO ADVERTISERS.—Changes of ads. should reach this office one week before date of issue, in order to insure insertion.

RECEIPTS FOR FARMER SUBSCRIPTIONS

The Maritime Farmer, instead of giving you one receipt in the year for a paid subscription, sends you 24, or one every two weeks. You will find it on the GREEN COLORED LABEL on which your address appears. The date printed thereon is that on which your subscription terminates. If on payment of your subscription the date is not changed within two weeks, please notify us. No other receipt will be sent.

JULY 22, 1919

WHAT COLORADO FARMERS THINK OF THE SILO

The following opinions from Colorado farmers were obtained by sending questionnaires to a number of silo owners. They are Colorado testimonials to the value of the silo.

"Ensilage has cut the cost of butter fat production in my herd 25 to 40 per cent."—W. C. Swinehart, Adams county.

"Ensilage feeding caused increase of 48 ibs. of butter fat per cow in my herd."—W. C. Swinehart, Adams county.

"I sold silage at $10 per ton on the place this year."—C. J. Birgasil, R. F. D. 1, Fowler.

"Harvesting the corn crop all at once instead of all winter with the wind blowing one-third of it away" is the testimony of W. A. Hobson, Swallows.

"My two silos have enabled me to increase the amount of stock that I can feed."—Victor Akin, beef feeder, Fort Collins.

"I like silage because it can be fed economically in any kind of weather."—F. P. Breniman, beef feeder, Fort Collins.

"Bigger cream checks and healthier cows," is the evidence of W. A. Atkinson, Hoehne.

"Silage keeps cows in healthy condition and increases efficiency of other feeds."—H. F. Lombard, Concrete.

"Silage saves veterinary bills and gives me a larger amount of feed per acre."—George S. Turner, Canon City.

"Ensilage is a cheap and satisfactory feed and the cows give down milk well in winter."—O. H. Chambers, Golden.

CULL OUT THE BOARDER COW

A good example of what cow testing is doing to help dairy farmers to cull unprofitable milk producers is shown by the experience of a dairyman who reports the results of his work in R. O. P. work. He found that one cow was paying him $2.40 for each dollar's worth of feed, while another returned only 58 cents. This dairyman lost no time in selling the poor cow, and five others which showed by test that they were not paying for the feed they consumed. This year he is producing milk at less cost, thus increasing his profits. He writes, "I have cut down on the feed cost by eliminating the boarders, and can still further reduce it by using more clover and alfalfa than was available last year."

THE SCRUB BULL

At a recent Ontario Winter Fair," writes Prof. Geo. E. Day, "the steer which was beaten in his class only by the steer which afterwards won the Grand Championship of the Show, was out of a little scrubby cow of no particular breeding. How did it happen that such a miserable little cow produced such a good steer? The answer is simple. The sire of the steer was a good Shorthorn bull.

"Perhaps an independently wealthy man can afford to use a scrub bull if he wants to, but the man who has to make his money off the farm cannot afford to use a scrub bull at any price—not even though received as a gift. The difference in the value of the progeny will pay many times over the difference between the price of a good bull and a scrub."

VISITORS WELCOME

The dairyman who makes an effort to handle milk in a sanitary way welcomes visitors to his farm and barns. He enjoys having them see the source of the products which they buy and the methods which he uses, and the fact that he is likely to have visitors encourages him toward better methods and use of better equipment. It is the dairyman who is careless about handling milk and whose methods are not up to standard who usually knocks against public inspection and closes his doors against the visits of his patrons. There is no better way for a local dairyman to advertise his product than to let it be known that he is glad to have visitors inspect his place, and that he takes pride in showing them his animals.

HAVE LADDER HANDY

Not a few farmers neglect to make preparation to protect their buildings from the dangers of fire. On many farms there is not a ledder long enough to reach to the roofs of the buildings where a fire may be stopped in its first outbreak. As the majority of fires start by sparks alighting on the roof, it stands the farmer in hand to be equipped for getting on to his roofs in haste, and not have to go to a neighbor to procure a long ladder. Any farmer who can handle tools, and every one should be able to do so, should make a good strong ladder and have ti ready for emergencies. Even at the high price of lumber, it is economy to have several good strong ladders on every farm.

THE NATIONAL VALUE OF CHARACTER

We are apt to think of character as belonging to individuals only, forgetting that groups of individuals form communities which by grouping in turn form large districts, until soon a whole nation is included. The old saying that "no nation is truly great and strong whose citizens are not great and good" is equally true to-day as when it was first spoken. Character is the greatest asset. This is as true of nations as it is of men and women who supoprt the nation.

WAR ON RATS

Farmers should keep up a constant fight against rats. They are enemies of the worst kind. Set traps, put out poison, clean up the premises to get rid of the breeding places, rat proof the buildings, keep a good rat dog and co-operate with your neighbors in ridding the community of rats. Don't wait until the governor of the state sets a rat day, but set your own rat day in which with your neighbors you institute a raid on rats. As long as rats are numerous every day in the year should be a rat day in which the fight of extermination is waged.

THRIFT KEY TO OPPORTUNITY

Thrift is the greatest asset an individual can have. He who lives up to his means, who lives from hand to mouth, can not weather unforeseen adversity. He can not meet the unexpected opportunity which knocks but once at a man's door. The thrift man has the golden key which opens the door to greater things.

MUD AND DUST

The muddier a road gets the more dust will result when it dries up. The sides of the ruts are ground to dust. The road bed that is kept well crowned, hard and smooth offers no place for water to stand, so it will not develop bad ruts or much dust. The road drag is one of the best implements for keeping a riad bed smooth, well crowned and hard, if it is used soon after each rain.

* * *

There is a whole lot of truth in the statement of a farmer who had made a close study of human nature, when he said: "Brother farmer, if you want your boy to stay on the farm and be contented, don't bear too hard on the grindstone while he is turning the crank." Many a boy has left the farm because his father was not considerate of him and did not realize the truth that young folks must not be expected to bear as heavy burdens as their elders wish to bear. The old saying, "You cannot put old heads on young shoulders," is a mighty good thing to keep in mind when dealing with young folks. Just look back to the days when you were young and wanted some joy along with the daily toil.

* * *

All users of farm implements should anticipate, so far as practicable, the necessity for repairs and replacements sufficiently in advance of the working season to make it possible to put their implements in good working condition before the spring operations begin.

Manufacturers and dealers declare that if they can know sufficiently in advance the needs of the farmers for repair parts, tese parts can be supplied when they are needed. If the needs are not known to the manufacturers and dealers until the actual time for use, troublesome and costly delays are likely to be caused—delays that may be felt in increased production at harvest.

* * *

The extra cost that is tacked on to a quart of milk after it leaves the farm may be justified under existing conditions and the present method of handling the milk business, but some day this food is going to be sent from the barn to the kitchen at far less expense. In order to do this it may mean municipal distribution, or some other way, but in any event it will mean less cost.

* * *

The modern dairy cow must be handled with understanding and her owner must have a knowledge of her wants and make every effort to supply them.

OBJECTS AND METHODS OF PLOWING TO PROMOTE GREATER FERTILITY OF FARM

How deep plowing should be done is quite an open question with many farmers, but the answer is regulated by the character of the soil and nature of the crops. Some sandy or light soils can be plowed to the depth of eight inches without injury, while others are impaired by plowing deeper than four inches. This difference is due to the soil formation and will readily become known on a farm or district from experience. On clay soils four to six inches will be found better, provided clover or alfalfa plants are used to break up the subsail. **The chief objection to plowing heavy clay or heavy loam soils year after year at the same depth is that it leaves a hard plow pan at the furrow depth that is apt to arrest the natural drainage, or moisture holding capacity of the soil.**

The depth intended to plow is determined by the kind of plow used. If plowing shallow it is best to use a narrow plow, ten or twelve inches, but if going ten inches deep the plow must be 14 inches wide to have room to turn the furrow over. Heavy, dry limestone soils give the best results when plowed seven and eight inches deep. The tendency, however, is to plow too shallow rather than too deep. The depth of plowing depends largely upon the type of soil and of sub-soil, and to some extent upon the crop raised. Deeper plowing is required for potatoes and root crops than for cereals.

Deep Plowing

Deep plowing on clay soils is objectionable if done all at once. It takes two or three years for the bottom soil, that has been thrown on top in large quantities, to become accumulated and get in condition for the plant to use the fertility that is there. It is all right to bring up an inch or so of the bottom soil when plowing for roots or hoed crop, once in a rotation, but to plow a clay soil eight or ten inches deep all at once is not a safe thing to do. The first cropping of such will prove unremunerative; the gradual way of bringing up the bottom soil is the safe way to bring a farm towards its ability to produce its maximum. By turning up an inch or so of bottom soil in the fall plowing and putting manure on that soil, thus gradually reaching to nine or ten inches deep, a farm will produce bigged crops than where shallow plowing is done and sub-soiling is left to clover and alfalfa. **Big yields year after year never come from shallow plowing.**

In plowing heavy clay soils the aim should be to prevent the formation of the hard plow pan by varying the depth from year to year. Also where deep plowing is resorted to there is less washing out of soils. It is a means of draining a soil also, by bringing it to such a texture that all water falling on it will be absorbed or pass through it. When soil is heavy this is hard to accomplish. Such soils, especially if heavy, may often be plowed into "lands" to advantage. Lands from 15 to 30 feet wide are often used, but lands 60 to 75 feet wide will drain the soil more effectively, because not enough water may flow into dead furrows from narrow lands to make sufficient current to carry it off. Level fields though fairly well drained, naturally or artificially, may be left in lands of 30 to 50 feet wide.

In Britain, where mose intensive cultivation is practised, there are no lands in the field, the underdraining that has been going on during the past 50 years is now so complete that one way plows are largely used, and level fields without dead furrows are universal.

To sum up deep plowing it may be considered that eight inches is sufficient for many soils, and rarely is it practicable to plow more than eleven inches deep. Most field crops feed much more deeply than is generally realized. Root crops and corn occupy the ground to a depth of four or five feet, according to the nature of the subsoil. But most of the feeding roots are in the plowed ground, because this is the richest, warmest and best ventilated part of the soil. Ventliation of the area in which the roots penetrate ein the soil, has as much to do with the healthy growth of plants as the ventilation of the barns has to do with the health of the animals housed in them.

Sub-Soiling

Another method of deepening the cultivatable area is by sub-soiling with a plow that follows the plow that turns the sod or upper soil. It does not throw the sub-soil on the top, merely breaks up the bottom and leaves it practically in the same place but broken and loose. About 30 years ago this method was practised by many farmers in iBritain, but it is not so popular now. The best method of having a deep soil in that country has now been proved to be with the practice of taking up an inch or so of subsoil every four, five or six years, according to the rotation practised on the farm. This has resulted in increased crop yields in roots and grain; in other words, it gives an extension of fertile areas by deepening rather than by widening. Where extension in surface areas cannot be procured, as in the confinedareas of a country like Britain, better results with less labor than is required on extended areas has been got by deepening the soil. It was found that the soil that was loosened by the subsoil plow quickly fell back again and became compact. It afforded only temporary relief and had to be replowed every few years with a subsoil plow to keep the bottom soil loose.

In Canada, where there is as yet unlimited choice, and areas in virgin soil, the tillage question has not become so necesary, and neglected farms and areas are the result. But when a farmer who has an interest in his business and elects to stay on his farm, he will find that he will double or treble the value of his holding by making a study of the closs of tillage that will best increase its fertility.

If one waits in the spring until the subsoil is dry enough to make subsoiling possible, the surface soil will usually be too dry to be plowed with advantage, and will have lost too much of the moisture needed for crop growth. Then, again, **loosening the subsoil in the late spring tends to cause the formation of large masses that wil limpede the movement of soil moisture.** In such a case it should be dones in the fal so that the larger clods may become disentegrated through the action of winter's frost.

The more general practice of underdraining is lessening the appreciation of subsoiling. Underdrainage loosens, deepens and areates the soli permanently and to a much greater depth than subsoiling. At present where subsoil plowing is done it is confined mostly to well-drained lands which have a hard-pan that is close to the surface. Subsoiling is injurious to a wet clayey soil tending it to puddle. It should follow, and not precede, underdraining.

The practice of shallow plowing and shallow tilling still lingers with the Canadian farmer, a clinging to the methods that gave esuccess to the first settlers. They forget that these pioneers were dealing with virgin soil. Shallow plowing was necessary then, but as soon as the native sod was subdued it was found that deeper plowing was needed. Farmers who persistently plow a shallow three to four-inch furrow and sometimes not at all for a year or two, the surface being sufficiently scratched to cover the seeds, could easily double the feeding crops by better and deeper tillage. **Good tillage—deep plowing, thorough harrowing, frequent cultivating—will delay the day when fertilizers will be needed, because it enables the farmer to get the most from the soluble plant food aready in the soil.** Thus is is seen that simply stirring the soil, the commonest work on the farm, and the work which often receives the least thought, sets at work agencies that exert a profound influence on the productivity of the land.

SOLDIER SAVES MONEY ON FARM EQUIPMENT

(From the Director of Information, Soldier Settlement Board, Otawa.)

Hon. Arthur Meighen dealt with the advantageous prices quoted to soldier settlers when the bill to assist soldiers in settling upon the land was in Committee of the House. He said:

Having decided that we ought to adress ourselves to the task of getting the soldier a better price in the purchase of his stock and equipment than the ordinary retail price, we entered into arrangements with the manufacturers of every article that the soldiier desires—that is, everything he is entitled to buy out of the Government loan. The Government, as is manifestly necessary, supervises every purchase. Not a single dollar of the money we loan to the soldier is spent except under the specific supervision as to every article by the Board itself, and in the determination of what he is allowed to purchase and the payment care is exercised and definite and iresistible rules are followed.

For example, the Board has determined that a man shall not be permitted to purchase a tractor; we did not think we should enter upon that phase of farming, as it is based upon a skill of operations that is beyond the capacity of a pioneer to be made a settler of. That is something which he could reach later on. If we permitted infraction of that rule we would be engaged upon payment and launching men upon work that perhaps they could not cope with, and so we do not permit it.

All the Soldier Requires

Limits are also placed upon the price that can be paid for horses, and so on. We have managed to succeed in effecting arranbements with the producers of all the goods that the soldier will require and would pay for out of his own money which redound t othe very great advantage of the soldier settlers.

In the first place we have effected arrangements with all, or at least all the principal manufacturers of agricultural implements, whereby the manufacturers of implements use their organization for the delivery of their implements as the soldier may choose, and they get those implements to the soldier at the wholesale price at that without any further charge whatever. In addition to that the manufacturers pay the cost of distribution, and pay their agents a special commission for handling the implements. The soldier pays nothing at all except the ordinary bulk freight rate on his shipments, which he gets at the wholesale cash price.

30 Per Cent. on Harness

As regards harness a still better arrangement has been made. The general saving which he makes on harness is 30 per cent. of the retail price. It is even less than the wholesale price, and he gets his choice. Our arrangement is such that the payment is made through the Board. The manufacturer of harness has no difficulty whatever. Shortly after the harness is delivered he gets his pay. Owing to the fact that there were considerable stocks on hand we made an especially advantageous arrangement as regards that commodity.

An arrangement is made as well whereby the wholesale price is secured for the soldier for his hardware. He can get it where he likes and pays the wholesale cash price and no more. He pays the wholesale cash price also for his lumber. They do not generally buy in less than carloads, in which case they get the mill price, but if they do not all they pay is the actual disbursement. The same arrangements have been effected as to the other commodities he buys, and I have here tables to show what the soldier settler saves at each point and what he would have to pay if he wrote buying as an ordinary purchaser. The total he saves is a most substantial sum.

(The Minister quoted figures from various distributing points showing that the soldier purchasing through the Board had effected an average saving of 21 per cent. on agricultural implements in April. He also quoted figures for horses, the average price being $152.

CUTING RED CLOVER FOR SEED

As a rule clover should be cut for seed when a large majority of the heads are thoroughly ripe. This may be ascertained by going over the field and rubbing a head here and there. If the seed will shell into the palm of the mand when the head is rubbed, it is ready to cut. If, however, the seed, in some of the heads is green and not properly hardened, the clover should be allowed to stand, even at the loss of a few over-ripe heads. It must be borne in mind that in any field there will be late flowering clover plants in which the seed never ripents. **A mistake is often made in cutting before the seed is ripe.**

Clover may be cut with the mower with a small table attached to the cutting bar so that the clover may be raked off with the hand rake. It may also be cut with the self-rake reaper and with the self-binder.

The binder is the best machine to use if the clover is heavy and stands up well . When cutting with the binder the cord should be removed and the spring slackened so that the binder will trip continuously. The binder has two boards to hold the sheaf, which boards should be slackened also in order to allow the clover a free course to the ground. In dropping to the ground the clover will not shell and will be light so that the wind and sun can easily dry it out. The windrow will be out of the way of the horses and machine and can be easily gathered with the barley fork.

As to the length of time the clover should be allowed to remain in the windrow, this will depend on the weather and on the condition in which the clover is cut. Sometimes it must remain two or three weeks. It is not wise, however, to alow the straw to become black and ruined for fodder. Just as son as it is well cured it should be gathered in.

SAVE CLOVER SEED.—NO OLD STOCKS.—HIGH PRICES ASSURED

Both the American and Canadian clover seed trade have practically no reserve sctocks of clover seeds being carried over for next season. On the Toledo market, red clover seed for autumn delivery advanced during the last two weeks in May from $19.90 per bushel to $21.80.

This situation indicates that special attention should be given to all clover seed crops in Eastern Canada. Most of our clover seeds are usually produced in Western Ontario, but prospects are very poor there this season as the new clover stand was badly damaged by the dry period of last summer.

nI districts with good clover crops, early cutting of the red clover ror hay will give the best chance for a seed crop. Weeds producing seeds which are difficult of cleaning from the thrshed clover seeds should be rogued from the standing seed crops.—Seed Branch, Ottawa.

HORTICULTURE.

RUST FLY

Pest of Carrots and Celery

By A. J. Gorham, M. Sc.

Last season the carrot crop in the gardens and farms about Sussex and other parts were badly affected by Carrot Rust Fly.

The chief damage of the rust fly is the riddling of the root with rusty colored burrows which impares its value and allows rot to start and destroy the whole root.

The first sign which appears in a field of carrots attacked by this fly is the reddish brown or rusty shade of leaves which eventually die; second, a cluster of fine small leaves at crown. The root will be found to have numerous fibrous rootlets.

The first generation appears along about the latter part of May or early in June. The rust fly measures about one-sixth of an inch long, has a black or dark green body, pale yellow head and legs, and black eyes. These flies lay eggs in holes or cracks near the young plants. From the eggs, yellowish white, legless larvae or maggots emerge and attack the carrot at the most susceptible part; that is, where it narrows down to the thickness of an ordinary root. After working in the root for four or five weeks, the maggots emerge and pupate in the soil. The escond brood appears early in August, and it is this brood which has given the most trouble.

The following control measures are suggested:

1. Rotation—Change the location of your carrot or celery crop year to year, using fields as far separate from one another as possible. Do not follow celery with carrots or vice versa.

2. A poison bait spray made up as follows: sodium arsenite, one-fifth ounce; molasses, one pint; water, one gallon. The sodium arsenite is dissolved in boiling water and then mixed with the molasses and properly diluted. It is applied in coarse drops by a sprayer or sprinkled about by means of a whisk broom dipped in the liquid. No attempt is made to cover the plants, as the flies are strongly attracted by the material. Perhaps, as in the case of the onion maggot, this solution could be applied on alternate lands, or checkerboard fashion, thus relieving the necessity of treating the entire field. Further experimental evidence is necessary in any case. The first brood which emerges in May should be controlled by the poison spray, but because of the uncertainty connected with the exact time of emergence of the second generation, this one cannot be controlled similarly.

3. Destroy all wild carrots on the place, as they are the breeding places for the flies. It is also well to clear up carrot or celery fields, removing small carrots which would be left in the ground over winter and destroying celery refuse about the fields.

It is stated that raking or cultivating fields to sufficient depth to expose the larvae to the action of the frost will kill many, and an early deep plowing of the land in the spring before flies have a chance to emerge should dispose of most of the others. What value the plan may have in the light of recent developments, I am not in a position to say.

PREPARING FOR THE HONEY CROP

The beekepper who gets the big crop of honey is the one who gets his bees erady to gather it. Much of the strength of the colonies depends on the way they are managed before the honey flow begins. If they do not get started early and build up fast they will not be in a condition to do more than hold their own or gather a moderate amount of surplus, but if they are made to build up fast and are kept from dividing up their forces by swarming, they will be so strong when the flow begins that they will store honey rapidly, and if the season holds out, will fill several supers.

The first thing to do is to find out whether the hive has a queen in it. To do this examine a few frames in the middle of the hive after the bees begin to fly in the spring. If they are showing eggs or larva in the middle of the frames you will be sure a queen is there, but if not you will be pretty sure that she has been lost, and will put a frame containing eggs from some other hive in exchange for one of the frames, brushing the bees off of each frame first before making the change. If you did not do this the bees of the hive into which it was put would be apt to kill all except the very young ones. The bees will rear themselves a queen from the eggs in this frame if they are queenless, and if not they will not suffer any harm from having it given them. You would gain time and make the colony stronger if you united it with some other colony, if it is very weak, or if you have another very weak colony with a laying queen that you could use. The two will stand a good chance to make a very strong colony while either one alone would not be likely to build up to be so very strong without taking bees from some other hive to help them. To unite, take the queenless colony and put it over the one with a queen, with a newspaper between them. When the bees have eaten their way through the newspaper and mixed with the bees in the lower hive they will have become well enough acquainted that they will not fight.

I have never fed bees much in the spring, and I do not advise the beginner to try it unless a long, wet, cold spell comes soon after the bees begin to fly and you see they have almost no honey in the hives. If you do have to feed you can do it by putting a super on top of the hive and then putting a half cup of this sugar syrup in a dish in it every night. Have the syrup hot, and made by dissolving one part of sugar to two parts of water. Put some cork shaving into the dish for the bees to stand on, unless the dish is made of wood so they can cling to it. They will drown in the syrup if this is not done.

The main attention the bees will need after they begin to get honey enough to feed the larva will be to give them plenty of room so they will not want to swarm. The entrance should be made just as large as possible, and a super put on top as soon as you see that the bees are sealing over honey in the outside frames in the hive below. When the first super is half filled raise it up and put a new super below it. The bees will finish filling the first and work on the second at the same time to a certain extent, and when you see the second is half full you raise the two and put another next to the hive. Keeping this up will insure even filling of the supers and at the same time give so much empty space next the hive that the bees will always think they have plenty of room.

The hives should be so located that they have the early morning sun and are protected from northwest winds, for the bees will start out early in the morning if this is done. Then the hives will be warmed up quickly and kept from being chilled by cold winds, and this will keep the beees inside at work making comb and feeding larva. Eraly heat has much to do with rapid building up.

When we take the best care to keep the bees supplied with room we cannot always prevent swarming. The next thing to do is to swarm them artificially, so we can do it when we please, and with no danger of losing swarms, or to let them swarm and hive the swarms on the old stand so as to get all the workers from both hives. As these are special processes too long to describe in this article we will not attempt it.—C. H.

POTATO BETTLES VERY ABUNDANT

By G. E. Sanders

It has been years since potato beetles were as abundant as they are this season. From present indications a

Massey-Harris

The Binder that Never Fails

The Massey-Harris Binder takes all the worry out of Harvesting, for its owner knows that no matter in what shape the grain may be, his "MASSEY-HARRIS" will handle it and get it all. Years of actual work in the field have proven that for heavy crops, or down and tangled grain there's nothing to beat the Massey-Harris Binder. Thousands of farmers now look forward with happy and easy minds to harvest, in contrast to the old-time anxiety that accompanies uncertainty, because with a Massey-Harris Binder they take no chances—it gets all that grows.

Trussed and re-inforced at every supporting point, it is unsurpassed for strength and permanence.

The Reel can be set in seventy different positions, from sweeping the Guards to 31 in. above the Knife, all positions being obtained through one Lever which is within easy reach of the driver. An Adjustable Reel Brace prevents the Reel from sagging.

The Knotter, so simple, with nothing to get out of order, always ties a perfect knot and ties it tight, with the band in the centre of the grain.

HANTSPORT, N. S.

large proportion of the fields will require treatment within a week of the appearance of the plants if the maximum crop is to be grown. On account of the fact that the adults or hard shells can very seldom be completely controlled by the early spray, it would be good business for all potato growers to make plans for thorough spraying when the plants are about ten inches high.

If the young plants are attacked by adult beetles within two weeks of their appearance, it is probable that the best treatment would be to dust the young plants with arsenate of lime. Spraying with arsenate of lime two pounds to forty gallons would be equally effective. Arsenate of lead or Paris Green may be used if arsenate of lime is not available.

When the plants are ten inches high or when the first larvae or slugs or soft shells, as they are often called, appear, growers should spray very thoroughly with a poisoned Bordeaux made up of,—

4 lbs. copper sulphate,
4 lbs. lime.
1½ lbs. arsenate of lime.

On making the Bordeaux the lime and the copper sulphate should be dissolved separately in upwards of twenty gallons of water and then poured together. In using arsenate of lime as an insenticide it is best to add it to the completed Bordeaux.

In New Brunswick where arsenate of lime is not available in all sections, arsenate of soda which is sold under the trade names of Arsenoid and Sol arsate may be used in Bordeaux only in place of the arsenate of lime.

Poisoned Bordeaux made according to the above formula should be applied every two weeks during the entire season after the plants are ten inches high. This will insure freedom from both insects and fungus diseases.

SPRAYING POISONS

Probably the standard poison for biting insects is still Paris Green. It is green, and therefor easily recognizable, and it is the best known to the average user. It would be well to lay in a supply of reliable stuff early. The market in some of these articles is incalculable, and the quantity obtainable limited. It should be remembered for what it is worth, however, that there are very much cheaper poisons which are equally effective, and steps should be taken at the earliest possible date to familiarize both the dealer and the man who uses them with some of these, and thus save a large part of the money which goes out of the country year by year for poisons. In the case of Paris Green it is literally true that a considerable proportion of the price is paid for the colour.

The effective principle in Paris Green is, of course, arsenic. When arsenic is combined with lime one resulting compound is arsenate of lime. In appearance this is a very fine white powder, the price is about one third that of Paris Green, and its killing properties greater since it is in a finer condition, requires less stirring and adheres better to the foliage. This poison is suitable for use alone or compounded with Bordeaux Mixture on all vegetable crops, including potatoes. It is already the standard spraying poison in the western part of Nova Scotia.

SPRAYING TO KILL INSECTS AND DISEASES

At this season of the year particular attention should be paid to the prevention of ravages by disease and insect pests. It is possible by a timely aplication of the proper sprays to control effectively many of our worst diseases and pests.

Spray materials may be divided into three classes. First, there the the fungicides, such as Bordeaux mixture and lime sulphur wash, which are used to control or prevent the development of fungous diseases such as Apple Scab and Potato Blight. Secodnly, there the poison sprays, such as lead arsenate, for the control of biting insects such as Potato Beetle, Tent Caterpillars, etc., and, thirdly, the contact sprays, such as kerosene, emulsion or nicotine sulphate, for the control of sucking insects like plant lice.

By selectiny the proper sprays under each of these three headings, a combined spray containing all three can be used and, thus, in a single application, one has a fungicide and a complete insecticide combined. A good combined spray is made up as follows: 4-4-40 Bordeaux, consisting of 4 pounds unslaked lime, 4 pounds copper sulphate, and 40 gallons of water, to which is added 3 pounds of arsenate of lead or 2 pounds of arsenate of lime in paste form (if the dry form is used, use one-half this quantity) for controlling biting insects, and if aphids or plant lice are present, one-third of a pint of nicotine sulphate should be added or, as an alternative, the lime sulphur could replace the Bordeaux mixture.

Do not delay the application until the disease or pest has become evident by its ravages, but make the application in time to prevent the damage. An application of spray is not a cure, it is a preventative.

Do not think that one application is sufficient. Remember that at this season of the year foliage grows rapidly and a large amount of new leaf surface is soon exposed after an application is made, and it is this new uncoated surface which is a source of infection. Three to four sprays during the season will be necessary to keep the leaves covered and the plants free from disease and pests.

Make the applications thoroughly, drenching all parts of the plant with a fine, mist-like spray. A coarse spray is not as effective as a finely divided one.

BLACK HEART

Will you please tell me all you know about black heart in apple trees? Do you think that Baldwin trees with this diseases will recover?—C. B.

Black Heart is a form of winter killing, and is very common in the Baldwin variety, even in the mildest parts of Ontario. Under these circumstances one is almost forced to the conclusion that Baldwin is scarcely hardy enough for the Ontario climate. This injury is very often induced and rendered much more serious by the forcing of trees for strong growth. In reality, a Baldwin tree should on no account be forced, even if recourse has to be made to laying the orchard down in sod for a year or two occasionally. If the trunk and main branches are perfectly sound without wounds of any kind through which decay might have gained an entrance, I should favor leaving them, providing they are growing satisfactorily. Black Heart will not kill a tree outright. So long as decay can be kept out the damaged wood simply dries up without any harm being done, but if at any point this injured wood becomes exposed to the air, decay is certain to set in. This means, of course, that it is much safer not to prune a Baldwin tree in its early years. If pruning is necessary, the wound should be covered immediately and thoroughly. It seems to me your only course is to leave the trees which appear sound and healthy and replace the others as fast as they begin to show signs of failing health.

Young trees will do well if cultivated. The young tree can not compete with grass and weeds. If the trees are planted 2 feet apart in rows, 8 feet apart, or 4 feet apart in rows, 4 feet, apart, the trees will in a few years throw enough shade to smother out the weeds. For good results, the cultivation must be kept up till the trees keep out the weeds by their shade.

DAIRYING

THE SEVEN DAY TEST OR THE "LONG GRIND"

When a real beginner goes out to buy pure-bred cattle, would it be advisable for him to depend on short time official records in deciding what to buy, or what not to buy, or should more confidence be placed on the showing the animal has made in the yearly Record of Performance Work?" This question was fired at representative of this paper not long ago by a dairy farmer, who is very much interested in the pure-bred stock business. Answering a question like the above one is not by any means the easiest thing in the world. A few score of men hold different opinions on this very subject, and all seem to have their own particular reasons to back up their views. The nearest the writer can come to arriving at an answer is to cite one or two of the ways in which he has heard the matter sized up by representative breeders.

A Believer in Short Test

"Well, if you really want my opinion, I am very strong for the short time, seven, fourteeen, or thirty day test," said one breeder whom we approached on the point. "I suppose, too, you will want to know my reasons. Well, here they are. To begin with, the test which is to be of most value, is the one which can be carried out under the most even set of conditions by all breeders alike, great and small, weathy or in ordinary circumstances. This to my mind is where the test of short duration has a marked advantage over the long grind. Every breeder who has learned the art of proper feeding has practically the same chance of getting his cow in the pink of condition for the test. Then when it comes to conducting the test itself, there are very few breeders except a few men of means to whom money is no object, who are in a position where they can milk four times a day, and handle all the rest of the extra work necessary in forcing cows at top speed for ten or twelve months. Then, on the other hand, there are also very few breeders cannot give test cows every last bit of attention that might be of any use, for a period of two weeks or perhaps a month. Hence, I claim that the short time test is carried by the rank and file of breeders under conditions more nearly alike than is the long test, and it is therefore a more reliable indication of what the animal can do."

The argument which this particular breeder put forward in favor of the short time test seems to be quite a reasonable one, and his point is well taken . The yearly test—if the best possible results are to be obtained—means milking four times a day for a large part of the lactation period, followed by a stretch of milking three times a day,—and undertaking almost too big on a farm where the available manpower is just barely sufficient to handle the routine work, as it comes along without having and additional chores added.

Quite a Different View

Another breeder interviewed, when asked his opinion as to the merits of the two different tests, expressed a view entirely differing from the one already ciited. 'Why, certainly, the Record of Performance yearly test is th eone and only way to size up a cow's capabilities," was his reply to one question. 'What a cow is capable of doing for one eweek, two weeks or a month for that matter, is not the sort of information I want about a cow before buying her. What I want to know is how big a year's work can I reasonably expect her to do at the pail. It is milk we are turning out here, and the Record of Performance record is the only real way of getting at the real capacity of the cow to produce milk throughout her whole lactation period. But here, too, is another point, the conditions under which a yearly record has been made should be published along with the record itself. It is all very well for the owner of the cow to advertise that the record was made under ordinary conditions. That statement means little to me, unless I am personally acquainted with the man and know pretty well the way he handles his cattle. The term "ordinary conditions" is too elastic to mean anything definite. If along with the record they would publish the fact that the cow was milked four times a day for so many months, three times a day for so many more, and so on, it would help greatly. To my notion, this would make the information which

Milks Any Cow
EMPIRE Milkers are self-adjusting. They milk any cow, regardless of whether she is a hard or easy milker, large or small teats, nervous or calm, large or small udder. Teat cups stay on without surcingles or harness.
Action in teat cups is always uniform, for the Empire has a Superior Simple Pistonless Pulsator. Never leaks vacuum. Pulsator comprises but five moving parts. Milk can't touch them. S. Kerr, Principal.

Butter Parchment at Farmer Office

the record gives a great deal more complete. However, this is just my opinion, and you can take eit for whatever it is worth; you have probably heard half a score of other views before now."

These two distincly different views on official and semi-official test work do not by any means begin to cover the ground, but they serve at least to show how some breeders are thinking on the matter and to indicate one or two of the strong points in favor of both kinds of test. One thing is certain, both the long test and the short has a good many followers, and probably will have unti lthe final trumpet sounds; therefore, the man who is out to make his cattle as valuable as possible through the medium of building up their reputation as producers of both milk and butter will put himself in line for the widest market, the best customers, as well as the most satisfactory business, by adding to his herd's history just as many of both long and short term records as working conditions will permit.

WHY CREAM TESTS VARY

The farmer who sells cream is sometimes surprised at the variation in the test reported by the creamery. In the early part of the summer the tests tend downward. The farmer should not assume that a variation in the tests means either carelessenss or dishonesty on the part of the cream buyeer. L. W. Morley of the University of Missouri College of Agriculture, mentions several factors which affect the richneses of cream and which make a variation in the test from time to time.

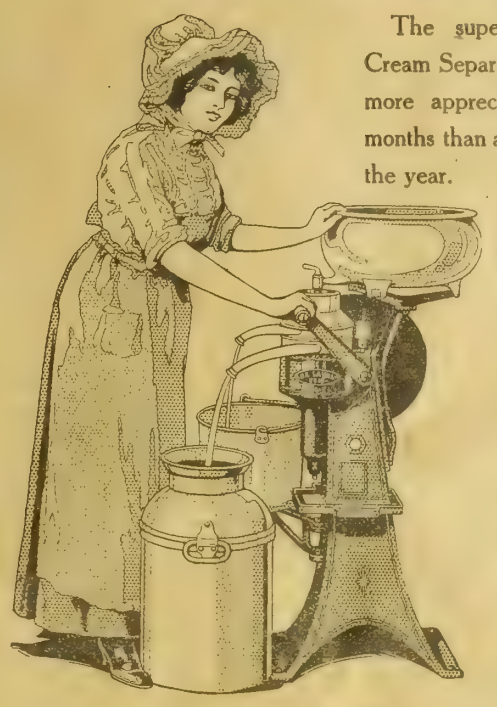
First of all the richness of the cream varies with the richness of the milk. In early spring and summer there are more fresh cows, which results in a lower testing milk and as a result of this the cream goes down in proportion. A herd of cows may produce milk averaging 4 per cent. in the fall and in the early spring and summer the average will run as low as 3.6 per cent. This much difference in the richness of the milk will cause a variation from 5 to 8 per cent. in the cream test.

The next most important cause for variation iis the speed of the separator. The faster the separator is run the larger the proportion of skim-milk and the smaller the proportion of cream. Consequently the high speed yield a richer cream. If a machine that is supposed to be turned 60 revolutions a minute is reduced to 40 the cream will be considerably lower in the test.

Another important cause of variation in cream tests, and sometimes the most important, is the amonnt of water or skim-milk used in flushing out the bowl. The difference of a pint used will make a noticeable difference in the test of the cream. A difference in the temperature of the milk separated wil lalso have some effect. Some separators are more sensitive to temperature than others. With some a difference of 20 degrees in the temperature of the milk when separated will make a difference of several per cent. in the test without affecting the thoroughness of the separation to any marked extent. It should be understood that these variations occur not as a result of more eor less loss of fat in the skim-milk but as a result of a larger proportion being taken out in the form of cream.

The milking machine is here to stay. It is a recognized implement at the present time and it has passed the experimental stage in many cases. Therefore, the person who doubts the advisability of such a machine might just as well doubt the advisability of a separator or a gasoline engine. It need an intelligent man to operate a milking machine, but for that matter it requires intelligence to operate any kind of a farm implement. The milking machine is a great labor-saving contrivance and it makes dairping possible on many farms. The milking machine can be criticized no more than any other farm implement.

Summer Advantages of the DE LAVAL



The superiority of the De Lava Cream Separator is more apparent and is more appreciated during the summer months than at almost any other time of the year.

Farmers appreciate the the De Laval during the busy summer season because of its large capacity and the fact that it is easy to turn and easy to clean.

With a De Laval the milk is taken care of in the shortest time and with the least effort—both important in hot weather when a number of other things have to be done.

Quick handling of milk and cream in hot weather maintains the highest quality of both, and often means the difference between profit and loss.

Over 2,500,000 De Lavals are in daily use the world over—more than all other makes combined More than 50,000 local agencies look after the needs of De Laval users.

If you don't know the De Laval agent in your community, write to the nearest De Laval office.

LIVE STOCK.

FIXING TYPE IN FLOCK OF SHEEP AND THE EVIL EFFECTS OF CROSS-BREEDING

In going the round of the fairs there is a good opportunity granted the visitor who follows them to note the work that is being done in the different districts. Among farmers who are taking an interest in sheep breeding, and had forward entries in the various classes, there is an apparent lack of having a fixed type in the breed they have selected for their flock. One of the chief difficulties with all successful sheep breeders is to get a uniformity of type in the flock. There is every indication that the high prices of sheep and their products, is to tempt many to use all the breeding stock that is available at home without due regard to the fitness for that purpose. Flock owners as a rule are apparently too careless in selecting their breeding ewes in not giving more attention to grading out their inferior individuals or keeping up the work of retaining only animals that show a marked similarity. In the long run it means loss to the sheep breeding industry to allow the flock even for one season to deteriorate. Numbers against quality do not count in summing up the year's balance on the sheep adventure on the farm, and therefore does not fulfill economy in the call for increased production. It is waste of expensive feed to give it to a nondescript lot of lambs that will not command a ready market. A small flock or a few sheep on every farm, made up of the best types of whatever breed chosen is far more in line with greater production than breeding wholesale, without any attempt at selection.

No farmer has a right to expect that inferior sheep will produce good lambs. The chances are many to one that the lambs from such stock will be still less desirable than their parents, and that means that they will not be profitable. Sheep that are weak, or show a marked inferiority in any important respect, should be rejected for breeding.

Breeding with Immature Animals

Also the practice of mating last spring's lambs, even though good for their age, will probably be as disappointing as those which follow the mating of older animals which are of inferior quality. The lambs are not fitted to endure the strain of bearing young. If they are subjected to it there will probably be a heavy loss of lambs soon after their birth, and the ones which live longer will not be as large or vigorous as the lambs from older ewes. Then, too, the growth and development of the young mothers will be checked, and their usefulness will be seriously impaired.

The expense of obtaining a pure-bred good typical ram is also a great deterrent in affecting increase in quality of the flock. There is thus the danger that the desire to secure a large number of lambs and the reluctance to obtain high-class rams, will lead to mating of many mature sheep that are not up to the standard of quality that ought to be maintained, and to the use of many individuals which are promising, but are too young for profitable breeding. The choice of such breeding stock is short-sighted policy.

And just as objectionable as in the case of ewe lambs, the use for breeding purposes of a ram lamb of only average merit. There are farmers who sell all their best lambs for the sake of the extra income, and keep a poor specimen for breeding. Even breeding with a ram lamb is not advisable, but breeding with the weakest one that has failed to get a buyer, is ruinous. **Using sheep under one year old, whether ewes or rams, is likely to make them uncertain breeders when they are older.** Even where the individuals are promising, and their inheritance is good, the use of immature sheep for breeding will cause a certain, and if long continued, a steadily increasing decline in the appearance and value of the flock.

Ewes, like dairy cows, should be selected strictly on the basis of performance. Ewes that produce large, robust lambs and suckle them well are the kind of sheep that pay for their keep and return a handsome profit. But the average flock owner does not know the individual merits of his flock. In the sorting out, in the fall, ewes that are well run down are the ones that are picked for the fattening pens. These very ewes unquestionably are the most profitable individuals in the flock, but on account of their low flesh condition have deceived their owner. Few flock owners keep a note-book of performance of their sheep and are compelled to rely on general appearance in selecting their breeding flock for the coming season.

Indiscriminate Cross-Breeding Ruinous

Another practice that is leading some flock owners to chaos is the art of sheep breeding in the crossing of breeds. The practice as carried on by many is a waste of time and money. There is no logical reason why any flock owner should resort to cross breeding of any kind of live stock today. The whole effort of the builder up of a pure breed was the elimination of the undesirable results found in crossing and mixing breeds and types. The first cross of two distinct breeds generally produces very good results, but the continuous intermixing or breeding together of these crosses is on the downgrade tendency in seeking flock improvement. To produce the best crosses a farmer has to keep two pure breeds and is therefore under the necessity of buying all his breeding stock.

Where pure-bred stock is maintained it is a great deal easier to select uniform stock for breeding purposes than where blood from several distinct breeds are intermixed. The prudent selection of breeding ewes is made more difficult each year when promiscuous crossing is followed from year to year.

Fall and Winter Keep

After the ewes have been all bred keep them in a healthy condition on pasture until cold weather comes, then give a little alfalfa or clover hay. **Do not feed timothy.** When frost and snow drives them in from the fields give a little oats and bran, one pound per head, with about 5 lbs. of silage per day, and all the hay you can spare. **Keep all corn away from them; it is ruin to a breeder's flock.** Everything a sheep requires can be grown on the farm but the bran. If corn is grown, sell the sheep's portion and buy bran. Silage is a good feed, but hay or grain must be fed with it. **Keep all dogs away from the barns after ewes become pregnant, or it will give trouble with lambs coming wrong or ewes sinking them at immature periods.**

KEEP THE YOUNG PIGS GROWING

It is obvious that if pigs are to be matured and marketed under nine months of age, they must be kept growing and developing from start to finish. Our forefathers wasted time and feed, making their pork cost them nearly double what was necessary, by feeding their pigs when young a small amount of feed, growing them along slowly and letting them rough it for nearly a year before they were fattened for market. That kind of growth and increase in weight is made at great expense. A pig will make its increase in weight much cheaper while young than is possible to make it later in life. Pigs when only a few weeks old begin to nibble at the feed given their mothers; a feeding pen or creep should then be provided for their use, so that they may eat by themselves undisturbed by the sows. Feed twice a day, just what the pigs will eat up clean of slop and some grain, gradually increasing the ration as their digestive capacity increases. It should be the aim to keep the young animals growing steadily as it is not economical to allow them to progress slowly at any time for a more or less brief period and then try to hurry them along by more liberal feeding. It takes a large amount of feed to fill out the lines of a shoat that has been on short feed for a considerable period of time and get it back to a form of thrift.

A Balanced Ration

Care must be taken not to over feed, however. Overfeeding is just as bad as underfeeding, and both are expensive. Some feeders think that they are not doing justice to their pigs unless the animals have feed to eat and as much more to run over. This is not only a waste of feed, but it is ruinous to the pig's digestion. A pig in order to do its best and at the same time do this on the least amount of feed, or, in other words, to make its gains most economically, must never be fed more grain than it will clean up in a short time. Neither should a second meal follow until the first has had time to digest. A pig should always come to its meals with a good appetite, and if it does not do this it is either being overfed or is sick, and in either case the best thing that can be done is to cut down on the feed.

It was long since demonstrated quite conclusively by the experiment stations as well as by experienced feeders that by employing a variety of feeds—a balanced ration, in other words—and giving the growing shoats access to good pasture in season, more rapid growth is made and at less cost, than when grain is fed exclusively. With a balanced ration the animals are developed more uniformly, bone, muscle and vital organs all being constructed at the same time, and therefore greater weights can be attained than by using only fattening feeds. The balanced ration also affords an opportunity for utilizing numerous cheap feeds most profitably, thereby lessening the feed bill materially, but at the same time securing just as rapid gains in the animals. There have been many times during the last few years when fat hogs commanded a high price in the markets, but at the same time grain and other concentrated feeds also possessed a high market value, hence the margin between the cost of production of the hogs and their selling price was slight at the best, and if the high priced feeds were employed exclusively an actual less may have been sustained. But if at such times an effort is made to diminish the cost of production by using, as much as possible, cheap feeds which can eb grown on the farm, paying returns can generally be secured.

Some Bulky Feed

It is now generally conceded that the cheapest as well as the easiest way of growing pork animals is to feed grain while the pigs have the run of good pasture. Any gain made from pasture on forage crops is the cheapest gain possible to make, and at the same time the green feed keeps the hog's system in fine shape. Forage crops answer a triple purpose in pork production. First, while the hog is primarily adapted to concentrated feeds, at the same time is requires some roughage. Grain feeds do not build up well in the stomach and are not easily penetrated by the gastric fluids, and for this reason the appetite is better maintained and digestion is improved by the use of some bulky feeds at all times of the year. Secondly, most forage crops supply sufficient protein to balance a grain ration nicely; and finally, they furnish the pigs with exercise while securing the forage; and exercise is essential for active and healthy vital organs in the growing animals. Even during the finishing process it is considered advisable to allow the shoats as much exercise as they care to take. The more concentrated their feed the greater the necessity of some exercise every day.

There are all kinds of pasture suitable for hogs—clover, alfalfa, rape, winter rye, oats and peas, etc. They may be sown at various times during the growing season, so that some of

Creonoid is a powerful, non-poisonous, inexpensive creosote product which is obnoxious to insects but not to animals or fowl. Spray it on cows to keep them from being tormented by flies. Spray in the hennery to exterminate lice. Result will be more eggs and more milk.

If you have any difficulty obtaining Creonoid write to

Ad. No. 6

them will be available at all times from early spring until late fall. Clover and alfalfa make very desirable summer pasturage, and they are more beneficial to the land than any of the other crops. All of the clovers are rich in protein and balance a grain ration nicely. It has been variously determined that when hogs have the run of good pasture they require or should have from one-half to two-thirds as much grain as when grain alone is fed. Rape is almost as good as clover in a way; what it lacks in quality as compared to clover it makes up for in quantity of forage produced. Rape may be sown at intervals of a few weeks throughout the summer so that a new crop will be coming on constantly. Under favorable conditions rape is ready for pasturing in six weeks from date of seeding.

PURCHASING STORE CATTLE

Among cattlemen who cater to the beef market it has always been a point of keen discussion whether it is more profitable for a farmer to rear his own stock or buy stores.

Some claim that they never find it profitable to grow steers, but prefer to let someone else look after the growing period. Other feeders believe that a reasonable number of young growing beef animals aer a source of profit to their owners during the period of their lives. But success in this depends largely upon the man, the kind of cattle bred, and his skill in raising calves.

The great disadvantage in buying rather than rearing lies in the fact that the farmer has great difficulty in getting the exact class of cattle he requires, and even when he finds a few the lot generally contains one or two bad doers, that run away with a large amount of the profit. As buying store cattle entails less trouble to the farmer than rearing them, the supply is generally not equal to the demand, and the price has to be paid for them is therefore almost invariably too high. Another great disadvantage is that the farmer does not know how the animals have been treated before he gets them, and, consequently, for a month of six weeks they make little or no progress. The system of buying stores also requires much greater capital expenditure than the rearing of calves.

On the other hand, the farmer who rears his own animals has always the class that he wants for the market, cattle that command the highest price. He also saves the middleman's profit for stores by no means an inconsiderable item. On a farm where rearing and feeding are combined much better use can be made of the farm grown feeds, some part of which will be more suitable for young stock than for old, and vice versa. The farmer who rears and feeds his own stock is more largely independent of any fluctuations in the price of beef or store cattle than the buyer of stores.

Conclusive Proof

can be furnished that the use of good Shorthorn bulls on the farm or on the range increases the size and improves the feeding qualities of the produce of the herd.

A Shorthorn bull is a profitable investment.

Cost of Rearing

Regarding the cost of rearing store cattle, the cost of keeping the cow is not nearly such a serious matter as it is with the dairy cow. A cow need not get any extra feeding, unless for a short period after calving, and if she calve about March or April this period need not be an extended one. Where calves of the right class can be bought, one cow of average milking quality can easily rear two, and do better to them by suckling, than can be done by hand when the labor bill is considered.

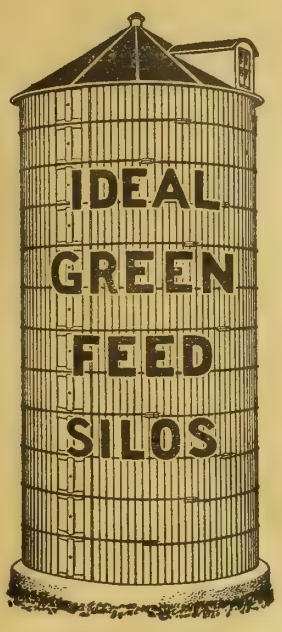
Some men are doing well using only what might be considered as cheap cross cows, counting largely on the influence of the bull to produce good feeders of quality and fattening ability. But for best results the best beef bulls should be mated with cows of a good beef type not necessarily pure bred. And also though the beef cow can be kept much cheaper than the dairy cow, reducing her winter feed to a straw ration while exposing her in the otuside during cold spells, is not at any time or under any market conditions conducive to a favorable bank balance.

The work of the feeder is devoted to the adding, by his feeding process, such amounts of fat over the body of the animal and through the muscular tissues as will give tenderness, flavor, and juiciness to the various beef cuts. It is the business of the feeder to so change the nature of the carcass, that the animal from being worth 8c or 10c per lb. live weight will after 4 to 6 months in the feed lot be worth 12c to 14c per lb. Thus; a 900 lb. feeder steer at 10c costs $90; a finished steer of 1,2000 lbs. at 13c, sells at $156. This gain or difference is got from the increase in weight and the spread in price.

A difference of opinion exists among buyers of feeders whether they should purchase smaller steers at a lower price per lb., that will take longer to finish, or larger and fatter steers at a higher price that can be finished in short time. Circumstances largely shape the course to be pursued. A man having plenty of rough feed, as straw, ensilage, roots, etc., but a minimum of grain might choose long keep steers, feed them cheaply through the winter and finish them on grass. Others prefer short keep steers. They finish quickly, can be sold in a short time, which gives a quick turn over of the investor's money. He can buy another lot of quick feeders, which in their turn can be sent quickly to the butcher. The feeding of short keep steers requires more grain and greater care than in the case of the thinner steers. The spread is not so great, either, but on the other hand the quick sales and rapid turn over compensates for this.

The basis of profitable steer feeding is animals of undoubted beef quality and growthiness. Added to this proper care and regular feeding of ordinary feeds as found on the farm should give fair profits. Trying to make profits out of expensive feds by feeding them to a bunch of steers that are crosses of the dairy breeds is on a par with the dairy farmer who feeds these expensive feeds to cows that average 4,000 to 5,000 pounds of milk. But there are lots of farmers in this business, and it is no wonder they demand better prices for their products.—O. V. J.

Simplicity



THE IDEAL GREEN FEED SILO is simple to erect, and simple to fill and to feed from, because of proper design, selected materials and skilful workmanship embodied in its building.

The IDEAL Silo simplifies farm work and feeding problems; the harvesting of silage crops is not as dependent on weather conditions as is that of dry-cured crops. Silage is easy to handle and the De Laval Company stands ready to help its customers with simple but accurate information about correct feeding proportions for all kinds of stock.

Write today to our nearest sales headquarters for our silo catalogue, which contains much valuable information about silos and silage.

MINNESOTA HOLSTEINS BREAK CONSIGNMENT SALE RECORDS

All previous figures for consignment sale averages were far surpassed in the First Annual Sale of Minnesota Holsteins, under the auspices of the Minnesota Holstein-Friesian Association. This initial event, which was held June 12 on the Schroeder Farm at Moorhead, resulted in a total of $217,795 for 76 head, which gives the sensational average of $2,865 per head. The highest previous average for a consignment sale was the National sale at Milwaukee in June, 1918, which showed an average of $2,430. The Cabana sale in May, 1919, now stands as the only sale of dairy animals boasting a higher average than this Minnesota event, but that sale with its average of $3,337, was a dispersal and not a consignment sale.

The fundamental factors in the success of the Minnesota Breeders' sale were that the breeders and sale committee alike went about the project with the determination to make it thoroughly representative of Minnesota quality and to tell the publir about it, truthfully, conservatively and in a manner to reflect the real merit of the offerings. The results of the sale came about simply because everybody back of the sale made good on their determination. The breeders selected of their very best, the sale committee was conscientious in its duty and rejected every animal offered that failed to measure up to the standard they had established, and finally an advertising campaign was put through more extensive and complete than was ever worked out for any previous state sale. These facts, in connection with the enviable reputation of Minnesota Holsteins in the matter of health, individuality, size and long-distance production were a practical guarantee of outstanding success.

The real sensation of the sale, as many expected, proved to be the proven sire, Sir Pietertje Ormsby Mercedes 41st, son of Sir Pietertje Ormsby Mercedes and the grand old matron Spring Brook Bess Burke, who has been called the greatest mother of the breed. Representing as he does a nick in breeding that has no superior in proven production of both milk and butter in long and short periods, combined with size and individuality, and with a splendid list of young daughters of his own, breeders from many sections of the country were present or represented, and determined to buy him at prices above anything previously paid in the Northwest. The bidding started off briskly, J. E. McMahon of the Ramsey County Home and E. C. Schroeder quickly carrying him to the $20,000 mark. At that point Good Hold Farms of Mentor, Ohio, entered a couple of bids but their limit was reached at $25,000. Gustav Pabst of Dousman, Wis., started at $26,000 and for a while it looked as though this might be enough to buy him. Soon however McMahon came back with a syndicate of other breeders and the bidding started again. At $35,000 Mr. Schroeder announced that he would take a half interest in the bull with whoever purchased him at whatever price he might bring. An exciting contest ensued between Mr. McMahon and Mr. Pabst. When Mr. McMahon's bid of $60,000 was raised to $65,000 by Pabst, the former threw up his hands, and Col. Mack struck off to Pabst and Schroeder the bull that is believed by those in the best position to know to be the most logical candidate to carry on the good work of Sir Pietertje Ormsby Mercedes. Mr. Gustav Pabst who is a brother to Fred Pabst, is developing a very high class herd at his Hollyhock and Tamarack Farms in Wauqesha County. It is thus assured that Sir Pietertje Ormsby Mercedes 41st will have a real opportunity for development. His two-year-old daughters already have made records up to over 27 lbs.

THE HORSE

DISEASES IN TEETH OF HORSE OWING TO NATURAL CAUSES OR DUE TO CARELESS ATTION

Most of the diseases of the organs of digestion in horses are blamed on the errors in feeding, but there are equaly as many of them due to teeth diseases, and the general lack of attention paid to them. The long tract of the intestines in the horse, and the fact that he has but one stomach with which to do the work, for which four are assigned to the cow and sheep, renders him sensitive to morbid disturbances of these organs. There is a closer sympathy in the horse between the stomach and his masticating organs; digestion properly begins with the teeth, and if they are out of order the whole digestive tract suffers.

Localized Inflammations

There are quite a number of localized inflammations which occur in and around the mouth, and it is of great importance to know the different causes that give rise to them. A number of these iritations are caused by the edges of the grinders or molar teeth wearing off the enamel, or the irregular growth of the teeth, become rough, and wound the inside of the cheek. In this latter case it is necessary to adopt a summary but effectual method of cure, namely, to rasp them smooth. Many bad ulcers are produced in the mouth by the neglect of this.

The teeth sometimes grow irregularly in length, and this particularly the case with grinders, from not being in exact opposition to each other, when the mouth is shut. The growth of the teeth still going on, and there being no mechanical opposition to it, one of the back teeth or a portion of it, shoots up half an inch or more above the others. Sometimes it penetrates to the bars above, and causes soreness and ulceration; at other times, it interferes partially, or altogether with the grinding motion of the jaws, and the animal pines away without the cause being suspected. The horse that has once been subjected to this operation should afterwards be frequently examined, and especially if he loses condition. Every horse that gets thin or out of condition, without fever, or any other apparent cause, should have his teeth and mouth carefully examined.

Lampas

Some of the lower bars occasionally swell and rise to the level with, and even beyond the edge of the teeth. They are very painful, and arise from inflammation of the gums, propogated to the bars, when the horse is shedding his teeth. Older horses also have at times ,but young horses are more liable to lampas than others. The horse suffering from it, should get some mashes and gentle alteratives to relieve him. A few slight cuts across the bars with a lancet or pen-knife, taking care to avoid the principal artery and vein of the palate, will relieve inflammation and cause the swelling to subside. To apply the old custom of searing and burning with a red hot iron is simply torturing to the horse and is of no remedial value. It may be prudent in the case of lampas to examine the grinders, and more particularly the tusks, to see whether either of them is endeavoring to make its way through the gum. If two incisions are made across each other on the top of the tusk, the horse will experience immediate relief.

Canker and Mouth Wounds in the Mouth

The mouth is injured much oftener than the careless owner suspects, by the pressure of a sharp or ill-fitting bit. Not only are the bars wounded and deeply ulcerated, but the lower jaw between the tusk and the grinders is sometimes torn to the bone. Partially developed tusks in a mare are very apt to be irritated by a rusty or badly placed bit, and ulcerated sores are the result. It may be necessary to have a sharp bit for the headstrong and obstinate beast, yet too many willing and docile servants are subjected to torment which is quite unnecessary. A perfectly good mouth fit in every way to masticate the food properly, can be imparied by the careless usage of the bit, so that the animal's health will be undermined, no matter how well balanced a feed for him is put up or how regularly it is given. For the inflammation of the mouth, small doses of aloes (three to four drachms) given at intervals of a few days, will have a cooling effect on the blood, and for the ulcers themselves, tincture of myrrh, diluted with an equal quantity of water, or an ounce of alum dissolved in 15 times the weight in water, may be applied with advantage. The writer used this mouth wash for horses as a preventative against bit sores or tenderness of mouth due to teething, and found it very effective. It is largely used in Britain among hunters to keep the mouth in perfect trim, so necessary to reining while engaged cross-country riding, and for the draft horse on the farm it will add to his comfort and health if his mouth is kept free from canker and wounds.

Decayed Teeth

When a tooth is decaying it is known by the following symptoms: Pain in eating, as shown by ejecting from the mouth masses of half-chewed food; flow of saliva and "slobbering" while eating; swelling of the gum, redness and pain around the diseased tooth; presence of a black spot upon it; sharp pain when the tooth is smartly raped; a fetid and sometimes excessively foul breath. Animal den-

tistry has not yet done so far as to fill and preserve decayed teeth. It is generally the grinder teeth that are subject to decay, and the only thing to be done is extraction. The chief objection to this is that the corresponding tooth of the opposite jaw increase in length and becomes an object of serious annoyance. It must be periodicaly examined ever after, and when it encroaches beyond its neighbors it must be rasped back to their level.

When a four-year-old horse is cutting his sixth molar tooth he is sometimes subjected to a distressing cough. He will take fits of continued coughing for 20 or 30 times without cease, and the cough sound is loud sonorous and prolonged. The cause of the cough is an irritation, that extendts to the throat and is aggravated by the replacement of the third temporary molar by its permanent substitute, which also takes place when the horse has reached his fourth year. The mouth should be washed with the the cooling mixture already described. A moderate laxative should be given, as the bowels will get diordered from the half masticated food. A daily dose of bicarbonate of soda, about one ounce, in water, should be offered the suffering animal.

Chronic indigestion in almost every case is due to irritation of teething and in every case where indigestion occurs the mouth and teeth should be examined.

HORSES REQUIRE SPECIAL CARE

How to get the most work out of his horses without overdoing them or badly breaking them down in their condition of thrift and usefulness, is a problem that the farmer faces every spring and summer season. Upon how well he solves this problem depends a great deal of the success of spring and summer farming operations. In warm weather thorough grooming is almost as important as feeding. Without it, dried sweat, dead skin and dirt clog the pores, make the hore uncomfortable and affect his health.

Look out for sore shoulders and backs, especially in plowing. Be sure that the collars fit. A collar too big is as bad as one too small. If the collar rides up, use a martingale or a girth running from trace to trace, back of the foreelegs.

When the horses are at work on a warm day, lift up the collars now and then to cool their shoulders, and wipe off the sweat and dirt with a bunch of grass.

Wipe off the harness marks on your horses when you stop work at noon and at night, and clean the inside of the harness, the collars especially. The salt sweat, drying on the skin and on the harness, is what makes the trouble.

If the skin is wrinkled under the collar or saddle, bathe it with diluted vinegar or witchhazel. If the skin is broken, bathe it with clean, warm water containing a little salt. Fix the collar, with padding or otherwise, so that it will not touch the sore spot the next day. A little carelessness at the beginning may cause a lot of trouble to you and suffering to the horse.

Clean your horse's at night, water them, give them a good bed and water them again after they have eaten their hay so that they wil not be thirsty all night. Let them rest an hour or more before they are grained. The observance of these simple rules will not cost you a cent, will make a big difference in their condition, and will add much to their comfort and endurance.

THE HORSE MANURE PILE FIREFANGING

When horse manure is left in a loose and open pile the air works in, dries out the manure and starts a strong fermentation. This results in what is known as "firefanging." In this condition the manure heats to a very high temperature, becomes very dry and takes on a light color. During this process a quantity of the nitrogen is lost, being burned away by the high heat. When the manure, however, is stamped down hard and well soaked with water, this firefanging does not occur, as the air cannot work in freely. Under these conditions of moisture and a compact pile the manure decays instead of burning, and thus become more available as a plant food. The best way to hold such manure is to stamp it down hard and firmly and see that it is kept moist by using much water on it. If the liquid from the stable can be poured over the pile this would make an ideal practice, but keep the pile firmly compact so as to keep out an excess of air. Manurs handled in this way will carry through the winter nicely. In order to make it more effective there may be added 40 pounds or acid phosphate to each ton of manure. This should be scattered all through the pile and add needed phosphorus to the manure, and also make a chemical combination to hold the ammonia. Handled in this way you will have a very good product.

WIDE WAGON WHEELS

That wide wagon tries are not an advantage on a wet clay road, at least, is urged by a writer in the Prairie Farmer: "I have always kept both wide and narrow-tired wagons," he writes, "and have had road experience enough to satisfy me that the wide-tired wagon is at its best when the roads are dry and hard, or where there is much sand. When the roads are soft like we have in the spring of the year, I find they are fully 50 per cent. more destructive to the roads than the narrow tires, and under these conditions they pull a third heavier.

"The reason for these two deficiencies is that the mud squeezes in over the felloe and the mud is lifted all the time on the four wheels, making additional draft and leaving a gaping rut, while with narrow tires the track will nearly fill behind the wheel. Now suppose it freezes that night after the ruts are made, and we take the wide tire next day along with the narrow tired wagon. The wide tire strikes more high bumps, pulls harder, making more wear and tear on the wagon, the team and the driver.

"Supose it snows a few inches that night and we try the wide and narrow tire. If there is much crown in the road your wagon goes just where it pleases, while the narrow tire will line up with the team. Of course, I mean for the wagons to be loaded. The heavier you load the wide-tired wagon the more it will slip, while it is just the reverse with the narrow tire. No broad tires on the road for me, except when the roads are dry. I'll use the narrow tires and pay fines for violation of road law rather than be compelled to use the wide tread."

ABSORBINE
TRADE MARK REG. U.S. PAT. OFF.

Reduces **Bursal Enlargements, Thickened, Swollen Tissues, Curbs, Filled Tendons, Soreness from Bruises or Strains;** stops Spavin Lameness, allays pain. Does not blister, remove the hair or lay up the horse. $2.50 a bottle at druggists or delivered. **Book 1 R free.**

POULTRY.

IMPORTANCE OF POULTRY RAISING

[illegible]am, in addressing [illegible] council recently [illegible]sembled poultry

Your business is a national necessity. Why? Eggs are one of the very few human foods that contain the essentials of growth; the material in foods that gives and maintains our normal power of resistance against disease. Canada is a young nation. It is our undivided duty, as well as the duty of our government, to see to it that these protective foods of nature are produced in abundance; that they are produced economically; and gathered, stored, and distributed with the least possible waste and in the best possible manner to the consumer, whether he be rich or poor. Every human being in Canada required eggs. They are a national asset. It is your duty as individual poultrymen to produce them; our duty, with the co-operation of the trade of our government, to see to it that they are not spoiled in transit or unduly increased in price to the consumer.

"The history of poultry farms would suggest that the poultry business is one of doubtful value as an investment. There can be no doubt but that many poultry farms have failed but the proportion of successful farms is on the increase and today most failures are due to lack of knowledge of the essentials. It has been a pleasure to me and to those associated with me to study, daily, weekly, monthly and yearly, the question of producing a large number of eggs at low cost. There has never been much trouble to get hens to lay from March to September but from September to March has been a difficult period of production. There have been many obstacles in the way but practically all of these can now be fairly well controlled. As illstration of this, the following figures are given for the production of 540 pullets during the months of November, December and January. These birds weer hatched in March, April and May, and may, therefore, be considered a fairly representative type. The flock consists of 340 Barred Rocks and 200 White Leghorns. These birds laid 8,441 eggs in November, 8,378 eggs in December and 6,396 eggs in January, or a total of 23,215 eggs, or nearly 43 eggs per bird during what is generally considered to be the worst producing months of the year. These eggs would represent at least at cash value, over $2.00 per hen. There are commercial poultry farms doing as well or better. There is no place in this country for the slacker. There is now no excuse for one having a flock of non-productive hens if the owner does his or her part. A good hen will give a favorable account of herself if you will give her the materials and the surroundings to make her comfortable and happy.

"It has long been known that pullets were the best egg producers, and most successful poultrymen have known that there was a time in the year to hatch these birds in order to have them lay during the common periods of short production. The great bulk of the chickens in this country are hatched during May, but most May pullets do not lay as many eggs during the year as their sisters hatched in March or early April. The difficulty has always been that should we meet with an accident with our early chicks, our main source of revenue for the winter months is gone. Fortunately we now know that flocks of selected yearling high layers may equal, and in some cases exceed, the annual number of eggs laid by an unculled flock of pullets. The old hen has been considered as doing fairly well if she paid her way from November to March, but I think we are safe in saying that a way at small expense, is now known to have her do better.

"Given a person who is not lazy and is fond of poultry there is every reason for a bright prospect for the future. Whether you keep a dozen hens in your back-yard or one hundred on a farm, or a thousand hens on a one-man poultry farm, the business is sound economically if one uses the information available. We might look upon the business in this way, that now we do not have to put all our eggs in one basket, there is more than one way of getting results.

"The situation at present may be looked upon in the following manner:

"The good laying hens can be told from the poor layers; there is a vast dicerence in the rate of growth and time of maturity of different strains of chickens; there is a best time to hatch; theer are many good feeds; eggs can be produced in fairly large numbers in any week or month of the year; the amount and kind of feeds commonly consumed by hens are known; the various grades of eggs are standardized; the co-operative gathering and selling of eggs has been a success; the knowledge of how to conserve our supplies during the periods of high production, so far as to give the consumer an egg that will poach six months hence, is available.

"My feeling is that we have now got our foundations laid. We can see over the top but the building is not complete by any means. A start has been made. We have no fears of the future so long as the poultryman is given a chance.

SUMMERTIME CARE OF CHICKS

Growing chicks should be provided with a house that will give them a place to stay in bad weather and at night. No particular style of house is recommended, but it should be so built that it will provide the chicks with ample ventilation, dryness, sunlight, freedom from drafts, and be so arranged that it can be cleaned easily and frequently.

In placing the chicks in their growing house for the first time, it is best to confine them for several days by erecting a temporary yard wherein they can run five or six days, until they learn where to return when the fence is removed and they are allowed their liberty. Care should be taken not to crowd the chicks by placing too many in any one house. When the chickens cover the greater part of the floor at night it is an indication that they are too crowded. At such a time they should be thinned out and placed in another house.

Feed for growing chicks may be divided into three classes, grain feed, dry mash and green feed. In addition to the grain feed the chicks are likely to find when on free range, a grain mixture should be given them morning and evening. The following rations should produce good results: Equal parts cracked corn and wheat. As the chicks increase in size, oats may be added. To cheapen this ration, it may be changed to two parts cracked corn and one part wheat. When one part of oats is added to this mixture, as the chicks increase in size, the ration may be changed to three parts cracked corn, one part wheat, and one part oats.

In addition to the above feed, a dry mash should be fed in a hopper to which the chicks have access at all times. Charcoal, grit, and oyster shells should be provided so that the chicks can help themselves whenever they want to. If a continued supply of sour milk can be obtained it may be fed separately in a pan provided for the purpose. Sour and sweet milk should not be fed alternately as such practice is likely to cause bowel trouble. Whenever it is possible, growing chicks should be allowed free range so they may obtain as much natural green feed as they need in addi-

Next term opens September 3rd, 1919.

tion to bugs and worms. When green feed can not be obtained on range such feed as sprouted oats, cut clover, mangel-wurzes, etc., should be fed daily.

The importance of clean, fresh water for chicks can not be over-emphasized. In very hot weather fresh water should be given to them twice a day. Whenever possible the pan of water should be placed in the shade to keep cool. The water pan should be cleaned every day before fresh water is added.

Plenty of shade should be provided for growing chicks. When allowed to range in an orchard or cornfield they will not only find ample shade and green feed, but will benefit the trees or corn as well as themselves by destroying bugs and worms. Sometimes sunflowers are grown for shade. Artificial protection against the sun's rays may be obtained by supporting frames covered with burlap a few feet above the ground.

Every effort should be made to keep the coops and houses clean and sanitary. Disease most frequently starts in unclean, poorly ventilated houses. The house should be cleaned at least once a week. Sand or litter of some kind should be scattered over the floor of the house, so as to assist in keeping it clean. When chicks are confined to a limited range, the ground should be spaded up at frequent intervals, so as to rpovide fresh ground for them to scratch in. Chicks should be examined frequently to see if they are infested with lice. When lice are found, every effort should be made to get rid of them, by applying a small portion of a mixture of equal parts of vaseline and lard to the top of the head and around the vent.

SCALY LEG A COMMON DISEASE

Scaly leg is one of the most common of all poultry diseases, and one which is not difficult to handle, if well understood. It is caused by a minute parasite that burrows under the scale of the leg, usually beginning at or near the feet.

The progress of this disease is very slow, usually taking several months from the time it is first noticeable until the disease has reached advanced stages, so as to be easily discernible by the rough appearance of the fowl's legs.

The two legs are usually affected at the same time, and to about the same degree. The continued irritation by the mite causes teh formation of a spongy, powdery substance beneath the scales, which raises them more and more ntil they are nearly perpendicular to the surface and are easily detached. In the most severe cases the joints may become inflamed, the birds go lame, the intense pain causes loss of flesh, and, in some instances, the death of the fowl.

We have often met people who regard scaly legs as an indication of age in a fowl, and the reason their flocks survive is because those with rough legs are sorted out and sold on the market. But such is not the case, for a pullet five or six months old may have an extremely rough leg, while a hen five years of age may have as smooth a shank as any pullet.

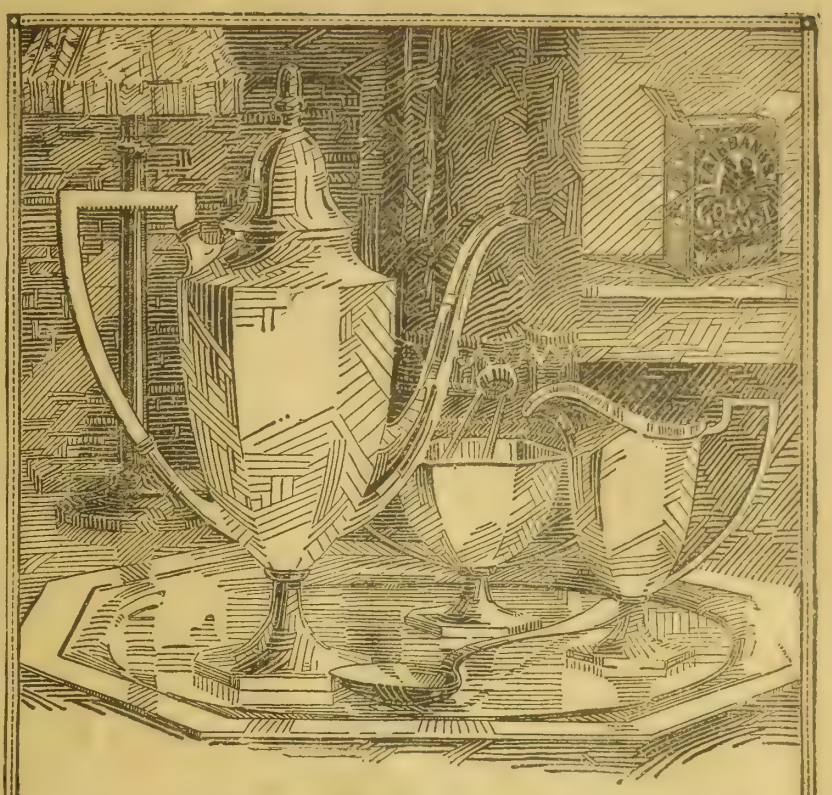
Treatment

This is one of the diseases that should be treated before any symptoms whatever appear, and this treatment is so simple and easily applied that there should be no loss or inconvenience from this inexcusable disease. Any kind of oil or grease, applied to the shanks before the disease is far advanced, will do the work, but for convenience of application a mixture of one-half each of sweet oil and kerosene, applied to the shanks by the use of a small machine oil can, is all that is necessary. This treatment will overcome the worst cases, if applied frequently enough; but in a flock where the disease is not prevalent, the application of this oil two or three times during the season will be sufficient.

The most convenient wa we have found for treating the fowls is to take the can and lantern at night when they are on the roosts, following from one end of the roost to the other, and squirt a small amount of the oil upon each shank. This will not only prevent scaly legs, but will keep the shanks in a bright, clean condition, and will greatly improve their appearance.

In cases where scaly leg has advanced to such a stage as to enlarge the shank to twice its natural size we would advise disposing of the fowl, except in cases where they are well bred and valuable birds; and in such cases we would advise applying an ointment composed of vaseline and flour of sulphur, wrapping the shanks with cloth and fastening it securely, allowing them to remain in this condition for several days. When the scales appear to be ready to come off, do not loosen too many of them at once, as they cause the fowl great pain, but when continually kept softened they will soon disappear.

Hens having scaly legs when brooding chicks will cause the chicks to be infected with this trouble. This is one of the diseases where "a stitch in time saves nine."



Makes Easy Work of Silver-cleaning

Yes, for silverware, too! You need only follow the directions on the Gold Dust package.

Gold Dust does away with gloves, powders and various polishing cloths. It saves muss, energy, time and patience.

Just a minute or two is long enough for ordinary cleaning. If the silver is badly stained or tarnished allow about five minutes. The tarnish is then softened and can be removed easily by gentle rubbing.

Rinse the silver in cold water after its Gold Dust bath.

LET THE GOLD DUST TWINS DO YOUR WORK

GOLD DUST

MADE IN CANADA

HOW TO MAKE SELECTION FOR EGG PRODUCTION

The rules that govern selection are as simple as A, B, C to any observing person. For instance, a hen that is slow to feather is lacking in vitality. Anyone ought ti know that. You can't stuff her and make her lay eggs. She is by nature a weakling. Hens do not lay eggs because they want to; they lay because they are strong and vigorous and egg laying is a natural result which they cannot avoid. That tendency must be bred in them.

Why, if the average farmer would give half the attention to his poultry that he does to his other live stock he'd find the poultry the oest investment in many cases. Success comes from being willing to discard.

Before mating your birds for another season, take one more look at them, and keep the following rules in mind when making your selection:

1. Market those which have been slow to feather or seem to lack vitality.
2. Keep the pullets which matured quickly and started laying first. Those which start laying when less than 200 days old will be the best layers if they have the right care.
3. Keep the late moulters.
4. Keep the birds with rather large, plump combs and wattles.
5. Hens with pale vents, pale beaks and pale legs have been good layers.
6. The skin of the best layers should be rather loose and flabby on the abdomen between the vent and breast bone.
7. The pelvic bones must be thin, straight, flexible and wide apart.
8. Market the hens which are baggy behind and which have a heavy, fat, thick abdomen which hangs down below the point of the breast bone.
9. Keep the hustlers and heavy eaters that go to bed late and with full crops.
10. Birds that have long toe nails that show no signs of being workers are usually unprofitable.
11. If a bird meets the above requirements, it should have a broad back, long body, be stoutly built and in good flesh.
12. If a bird is not moulting and still has a small dried up comb covered with a sort of whitish substance, or if a bird has thick or crooked pelvic bones, which will be found on each side of the vent and above the point of the breast bone, these are always money losers.

No man or woman can afford to keep and feed a flock of drones at the present prices of feed but the good layers will make more profit than in any previous year.

No poultry house will be found comfortable for the birds unless it is kept clean and free from parasites of every kind.

The two important things to be considered in planning the farm poultry house are the comfort of the hen and the comfort of the caretaker.

The question of profit in keeping hens has never been satisfactorily settled.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N B. solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

Creeping into the lives of men everywhere is the thought that co-operation is better than competition—we need one another. And by giving much we will receive much.—Elbert Hubbard.

"MOTHER'S WAY"

Betty was so lonely she wanted to crawl away out of sight and have a "good cry." Bob was a darling and all his people had been lovely. She had everything to make a charming home for a young bride, but she was lonley. She looked out on the back porches of the apartments abutting her own. There was Mrs. DeHaven, a pretty little woman, who never came in her kitchen except to give orders to the maid, and there was Mrs. Hastings, and Mrs. Greene, all young, all brides, and yet not one of them had called on Betty.

"If it were not for Bob, I'd go straight back home to the country, where people are human and care whether you live or die. If I'd been a young bride in the country everybody would have called by now. Bob's people are away out on south side, and it's a Sabbath day's journey just to go and come, and all day long, day in and day out, I haven't a single soul to say a word to but delivery boys, from 7.30 when Bob leaves, until 6, when he returns." Betty was small and forlorn looking as she dabbed a handkerchief to her wide, blue eyes. "I wish," she went on, "that mother could manage to get up for a while. But dad needs her—and——. But so do I. It's been six whole months since I gazed on my mother's face—and I do——"

"Why," Betty raised her head and listened intently, "whatever can that mean?" She rose and hurried to the kitchen door. "That sounds like mother, and coming in the back way!" Betty ran out the back door and down the single flight of steps and grabbed in her arms a small figure with twinkling blue eyes, silvered hair, and bonnet awry.

"Mother!" she squealed, and stopped on the landing for another hug. "Where in the world did you drop from? And why did you come in the back way, and why didn't you send us word, so we could meet you?"

"Land sakes, child, but it's good to see you. I just told pa I couldn't wait another minute, and I started right off, 'tween two days, as the sayin' is, and I got your gardener to bring up my bags the back way and I came right along with him——"

"Janitor, dear—" And, oh, I could eat you. I'm so glad to see you!"

"Janitor is it? Well, wait a minute. I want to let a lady who's been kind in bringing me up in her automobile know that I got here all right. There, she lives right over there." Betty's mother walked to the porch rail, waved a hand airily, and called chummily, "I arrived all right. Run in some time. I'd like to have a chat with you." Then to Betty, "that a fine little body over there; made me think of home folks, so kind and sort of commonlike——"

"Mother," Betty managed to get a word in at last. "Where did you meet Mrs. DeHaven, and how in the world did you get acquainted?"

'She was at the train waiting for friends who failed to arrive, and I thought she looked like a companionable body, and I smiled at her, and she smiled at me, and then I told her I had a girl living here and asked her to show me the way to get here, and she insisted that get right in her car that was waiting out front and I came right along with her. Then when we got here, I asked the janitor, you call him, to fetch up my bags, and I followed him right along."

"Mother, that's the wealthy, stuck-up Mrs.. DeHaven, and she's never even spoken to your daughter since she lived here." Betty took her mother's hat and smoothed her hair and hustled about as happy as a lark.

Her mother nodded. "Did you speak to her, daughter?"

"No. You see, I'm the newest comer here and I thought they ought to call on me——"

"Yes, I guess that's etiquette, but I reckon they don't stick close to that in a big city. But, daughter, there's one thing you'll find is always observed everywhere you go, and that is a touch of human nature. Just smile and follow it up with a kind word and a good act, if you get the chance, and, land sakes, I shouldn't wonder if your house would be the meeting place for the whole neighborhood before long."

"Just the way yours is back home?"

Mother nodded again. "Let me get my own tea ready. You just tell me where verything is and I'll do the rest. It'll make me feel right at home quicker. Then you ought to rest quite a bit now. I was telling that nice Mrs. Greene who came up from the last station on the same train with me and said she lived here in the city somewhere about you, and that I was coming to stay until everything was nicely settled."

"Mother, you're a darling! What did day say? Will he be able to manage without you that long?"

Mother, making toast, replied: "Of course he will, a great big fellow like he is. Well, it's high time he learned to get along with me away, for I've stuck around home till all you children are away and settled and now I'm going to have a little spell of visiting. But I was telling you about that Mrs. Greene. She said she wished she had a mother to come to her; that she's so lonely she could cry. She lives out this way in something like 'Recall Place.'

"Why, that must be Mrs. Greene right along the next street. They call that Recall place and this is Fifty-second street. Why, she has a house full of company all the time. And she's so lonely.

"Said they were her husband's people who come in and boss things around, and she longs for a good friend, and would give anything if her mother was living."

"Mrs. Greene!" Betty murmured. "You never can tell, can you, mother?"

"Never, honey. And don't you know, I think that is the great secret of life—say the little word; do the little deed, for you never can tell how much the other fellow may need it. Don't take time to feel sorry for yourself; get busy keeping the other fellow from being sorry for himself."

"That's all right to tell, mother, but everybody does not meet with the reception that you do. Now, there's that Mrs. Greene. She's lived next to me for nearly a year, and she's never thrown a smile in my direction."

Mother nodded again. "Yes, she has a kind of haughty look," she said. "I noticed that, and then I smiled at her and she smiled, but drew her face straight quickly as if she didn't want anybody to see it. Thinks I to myself, there's something wrong here. So I leaned over—she sat right in front of me—and said, 'Excuse me, but did you knit that handsome scarf yourself?" And she said she had, and then I got to telling her that I'd knit three sweaters so far and was going to do more. She said she didn't think she could manage a sweater, and I asked her to let me show her, and I got out my stuff, and we had a real nice visit together, and when she departed she had learned how to do a sweater."

"Mother, your'e a wonder you get acquainted with a woman on the train, wheedle her out of her grouchiness, teach her to do something useful, get acquainted with and tame a crank, visit me and cure the blue imps, and now you've go tea and toast ready for me, and you haven't been here an hour. Wait: there's some one at the kitchen door." Betty tripped to the door. "Mrs. DeHaven's maid with a glass of preserved figs for you," Betty announced when she returned to the dining room. "And, mother, Mrs. Greene just waved to me from the kitchen window. I wonder what it is about you——"

"Just a touch of human nature, honey. You try it and see."

'I will. And then I'll teach it to—" Betty smiled at a pleasant fancy.

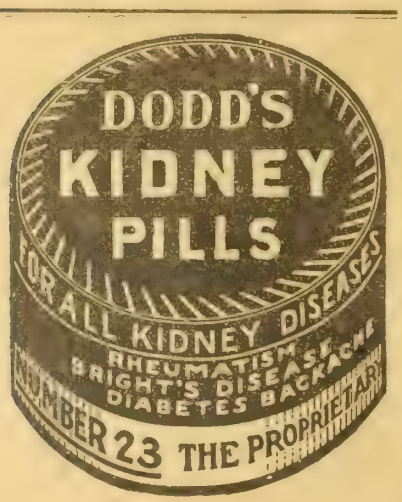
SOME PRINCIPLES IN THE COOKING OF THE COMMON VEGETABLES

The object of cooking vegetables at all is to render the cellulose and starch of which they are mainly composed (leaving water), digestible. Nature gradually carries on the proces of softening them, in their ripening, by means of the sun which heats the air and the soil, while woman completes it by the artificial or stored up heat of coal, oil or electricity.

Cleaning.—All vegetables should be thoroughly washed. Green vegetables such as spinach, beet tops, dandelion etc., should be washed in a collander with a stream of cold water running through it. Some root vegetables can be cleansed, only by being scoured with a brush. Cabbage and cauliflower should be soaked in salt and water for at least half an hour to rid them of insects. All vegetables should be kept crisp and fresh by being completely immersed in cold water for some time before needed. Limp lettuce, shrivelled beets and celery, potatoes, carrots, turnips and beets, peeled and thrown unwashed into tepid water, and left to soak half out of water, present a sorry sight of color and texture when brought to the table.

Preparation.—Peel thinly or scrape the root vegetables, cutting away all woody parts. Boil the shells of fresh, green peas and put the peas to boil in the shell liquor. Keep the liquor of spinach and asparagus to make the sauce to put over them when cooked. Potato water helps to make a rich meat gravy. The waste from table celery should be dried and kept for soup. Break or cut neatly into pieces of uniform size the vegetables to be cooked, so that they may all have the same heat.

Cooking.—Take a loaf out of nature's note book. Continue or reverse her processes, in the cooking of vegetables. The harder the vegetables, the longer they should be soaked, and the longer and slower they should be cooked. Tender vegetablese may be boiled rapidly. There are two ways of cooking vegetables, boiling and



ROYAL YEAST CAKES

There is more energy in a pound of good bread made in the home with Royal Yeast Cakes than in a pound of meat. Bread making is a simple operation and requires no previous experience. Full instructions in Royal Yeast Bake Book, mailed free on request.

baking. Fresh peas and beans may be boiled first, and finished up, in their own fluid in the oven. Most vegetables retain their flavor better and require less watching if cooked in their own liquor in the oven, in a covered porcelain dish called a casserole. Try cooking the vegetables in this way, if it is new to you.

Salt and Pepper.—Add the salt shortly before dishing the vegetables. Remember the saying of a famous French chef, "Monsieur, I am pleased that none of the gentlemen last night touched the salt cellar. I could not desire for a finer compliment."

THE ICELESS REFRIGERATOR

A companion convenience to the fireless cooker for the hot summer days is the iceless refrigerator, or milk cooker. This consists of a wooden frame, covered fith canton flannel or some similar material. It is desirable that the frame be screened although this is not absolutely necessary. Wicks made of the same material as the coverings rest in a pan of water on top of the refrigerator, allowing the water to seep down the sides. When evporation takes place the heat is taken from the inside, with a consequent lowering of temperature. On dry, hot days a temperature eof 50 can be obtained in this refrigerator. The following description will aid in the construction of this device:

Make a screened case 3½ feet high with other dimensions 12 by 15 in. If a solid top is used, simply place the water pan on this. Otherwise fit the pan closely into the opening of the top frame and support it by a 1-inch cleats fastened to the inside of the frame. Place two movable shelves in the frame, 12 to 15 inches apart. Use a biscuit pan 12 inches square on the top to hold the water, and where the refrigerator is to be used indoors have the whole thing standing in a large pan to catch any drip. The pans and case may be painted white, allowed to dry, and then enamelled. A covering of white canton flannel should be made to fit the frame. Have the smooth side out and button the covering on the frame with buggy or automobile hooks and eyes, arranged so that the door may be opened without unfastening these hooks. This can be easily done by putting one row of hooks on the edge of the door near the latch and the other just opposite the opening with the hem on each side extended far enough to cover the crack at the edge of the door, so as to keep out the warm, outside air and retain the cooled air. This dress or covering will have to be hooked around the top edge also. Two double strips one-half the width of each side should be sewed on the top of each side and allowed to extend over about 2½ or 3 inches in the pan o fwater. The bottom of the covering should extend to the lower edge of the case.

Place the refrigerator in a shady place where air will circulate around it freeley. If buttons and buttonholes are used on the canton flannel instead of buggy hooks the cost should not exceed 85 cents.

A TIMETABLE FOR VEGETABLE COOKING

Potatoes, new, will take about 15 minutes, old potatoes, 25 minutes. Onions and Spanish onions, from one to three hours. Old carrots, one and one-quarter hour. Young carrots, 25 to 35 minutes. Young cabbages and greens, 15 minutes. Old cabbages, 25 to 30 minutes. Cauliflowers, 15 to 30 minutes. French beans, 15 to to 20 minutes; 30 minutes may be allowed for quite old beans. Vegetable marrows, 20 minutes. Salsify, from two to two and a half hours. Aritchokes, 30 to 35 mintes. Turnips, the same time. Celery, boiled or braised, two or three hours. Young green peas, 15 to 20 minutes, and old ones 35 to 40 minutes. Spinach, 15 to 20 minutes. Brussels sprouts, the same time. Board beans, 18 to 35 minutes. Beet root, one and a half to two and a half hours.

"I Am So Afraid it is My Heart"

VERY many people live in constant dread of heart trouble when the heart is in no way diseased.

There is perhaps no organ in the human system which is worked so hard and yet the heart seldom goes wrong so long as it is supplied with plenty of rich, red blood.

In fact the heart repairs its own waste and plods on, lifting tons of blood each year and pumping it through the body.

But the heart's action is the result of the contraction and expansion of muscles and these muscles are operated by the nervous system. When the blood gets thin and watery and the nervous system is starved the action of the heart, just like that of the stomach, bowels and other organs, is slowed down.

As a result, you are easily tired out, experience shortness of breath, palpitation of the heart and general bodily weakness.

The quickest and most rational way to overcome this condition is by the use of Dr. Chase's Nerve Food to enrich the blood and build up the exhausted nerves.

With the nerves in a run-down condition you are sure to get downhearted and discouraged and to imagine that all sorts of dreadful things are likely to happen to you.

But when you have been using the Nerve Food for a week or two you will begin to see the silver lining to the cloud and to realize that you are on the way to health, courage and happiness.

Mrs. Nellie Dertinger, Simcoe, Ont., writes: "I was a great sufferer with my nerves and with pains about the heart. I could not sleep at nights and though I tried several doctors could not get much relief. A friend advised the use of Dr. Chase's Nerve Food and I am happy to say the results have been a surprise. My health has been built up wonderfully. I have no more pains about the heart, my nerves are steady and I sleep and rest well."

Dr. Chase's Nerve Food, 50c a box, 6 for $2.75, all dealers or Edmanson, Bates & Co., Ltd., Toronto. The portrait and signature of A. W. Chase, M.D., the famous Receipt Book author, are on every box.

THE HOME LAUNDRY

The laundry should contain besides the washer and tubs, two or three pails for drawing water; a long, smooth stick for stirring the clothes while boiling; one medium sized tin pail; one large dipper; one large and one small jacket; two cotton bags, in which the most delicate articles can be placed before being boiled; one or two high wooden clothes-horses, and a line on which to dry clothes in bad weather; an ironing table; a closet for holding irons, ironing blankets, etc., is very convenient. In this closet should be kept 5 or 6 dozen clothes pins, a board 1½ feet long and 8 in. wide on which to iron shirt bosoms; a paper or cushion of pins; and three or four good iron holders.

PILES Do not suffer another day with Itching, Bleeding, or Protruding Piles. No surgical operation required. Dr. Chase's Ointment will relieve you at once and as certainly cure you. 60c. a box; all dealers, or Edmanson, Bates & Co., Limited, Toronto. Sample box free if you mention this paper and enclose 2c. stamp to pay postage.

Cramps in Stomach

Never Suffered Worse Pains.

There is no other kind of bowel trouble that comes on one so quickly and with so little warning as an attack of cramps in the stomach. These are very painful, and when you are seized in this way, and are all doubled up, you want a remedy you are sure will give you relief, and give it quickly too

You don't want some untried medicine that might only help you. You want Dr. Fowler's Extract of Wild Strawberry. Every one who has ever used it knows that a dose or two will give instant relief.

Dr. Fowler's Extract of Wild Strawberry is one of those remedies that should be in every house, as no one knows just when some member of the family may be attacked with diarrhoea, dysentery, cholera, cramps colic or some other bowel complaint.

Mrs. S. E. Clark, Dorion Station, Ont., writes:—"While visiting my mother in town, I was taken very sick with cramps in my stomach. I don't think I ever suffered worse pains. I sent and got a bottle of Dr. Fowler's Extract of Wild Strawberry, and in a couple of hours I was all right again, and able to ride eight miles home in the evening. I can't praise your wonderful medicine enough."

Dr. Fowler's Extract of Wild Strawberry has been on the market for the past 74 years. Don't experiment with new and untried remedies. Refuse substitutes. They may be dangerous.

Price 35c. at all dealers. Put up only by The T. Milburn Co. Limited, Toronto, Ont.

SWEET SANDWICHES FOR THE PORCH PARTY

By May Belle Brooks

Sandwiches with a sweet filling are more wholesome than heavy cakes during hot weather—and ever so much easier to make. The only requirements are neatness and a generosity of filling. By cutting the bread in various shapes, variety is introduced. For some reason or other, possibly because it resembles a cake, the round shape is the most attractive for this sore of a sandwich. A sharp biscuit or cooky cutter will produce neat forms. Be careful to have the bread well buttered before spreading on the filling. It is a good plan to butter the loaf and then cut off a slice, rather than buttering after the slices are cut.

Grape juice, sweetened and cooked to a jelly consistency with a little corn-starch, is a new idea for the sweet sandwich. Be sure to cook it (using a double boiler) about ten minutes or the starch will have a raw taste. Another excellent filling made with corn-starch is this: Put two-thirds of a cup of granulated sugar, two etaspoonfuls of cocoa, one-half cup of cold water, and a tablespoonful of butter in a double boiler. When the butter is dissolved, stir in two tablespoonfuls of corn-starch dissolved in one-half cup of water. Cook ten minutes after it tsarts to boil. Cocoanut, nuts, or fruits may be added and the cocoa omitted. While warm, spread on the bread.

Jams are always convenient, and a particularly nice filling is made of peach jam and chopped almonds. Honey and nuts are food for the gods. Grated chocolate mixed with ground nuts and enough sweet cream to bind the mass will please the most fastidious appetite. Another popular combination is peanut butter and ground seedless raisins.

All of the candied fruits make delectable fillings, either alone or combined with other ingredients. A favorite calls for equal parts of candied pears, citron, and ginger, all chopped fine and thinned with a little fresh pineapple juice or other fruit juice one may have on hand. Spread between the thinnest rounds of brown bread. Fresh pineapple, shredded and mixed with an equal amount of ground pecans and with just enough thick syrup to give it body, has refreshing qualities.

Lady fingers, a trifle stale, make good sandwiches with a dainty filling like the following: Candied cherries and raisins—a little more of the cherries than raisins—run through the chopper and flavored with rose extract. If too thick, thin with orange or cherry juice, or a little hot water will do.

If you wish something especially toothsome, try mashing six bananas to a paste with lemon juice, honey, and whipped cream. Baked bananas mashed to a pulp is a novel suggestion, but it needs lemon juice to relieve a certain flatness of taste.

Lemon preserves, made like orange marmalade, except that only lemons are used, is one of the daintiest additions to the fruit cupboard. It comes in handily when a plate of sandwiches is wanted in a hurry. Spread between bread, crackers, or sweet wafers, it is as nice a tidbit as any one would care to eat on a sultry afternoon with a glass of lemonade or iced tea.

Lemon honey is something that will keep indefinitely. To make it, heat in the double boiler six tablespoonfuls of butter, one cup of sugar, the yolks of three eggs, and the grated rind of one large lemon. When it begins to thicken, add the juice of the lemon and cook until thick like honey.

Dates are good mixed with orange marmalade or apple jelly with a sprinkling of cloves. And they are equally good with nuts. Raisins and nuts are always easy to obtain, and no sandwich could be nicer than these two ingredients, ground fine and mixed with thick cream.

A filling that all children enjoy consists of cocoa blended with sugar, ground walnuts, and cream enough to make a soft paste. Add a flavoring of vanilla and cinnamon.

Many sweet things are frequently combined with cheese, which gives a sandwich a tribe less cloying. Dates and cheese are especially harmonious, and watermelon preserves also combine favorably with it. Cottage cheese mixed with apple butter is new. A different way to make up a sandwich is to cover one slice of bread with soft cheese and another with ground raisins, then press together. A bit more unusual is the combination of ground popcorn, gooseberry jam, and cheese. Or orange marmalade and cheese.

Marshmallows have earned a name for themselves in fancy conceits for the tea-table. They may be melted alone and poured over thin slices of toasted bread or crackers or cakes, or mixed with candied fruit or nuts, or melted chocolate. Sweet melted chocolate, either by itself or embellished with fruits and nuts, spread while hot between the slices, is quite tempting enough for most palates. Fudge sandwiches are made by spreading the fudge before it sets between bread and allowing it to cool before serving.

Maple walnut sandwiches are delightful. Boil together one cup of maple sugar, one cup of granulated sugar, and one cup of rich milk or cream. When it reaches the soft-ball stage, add a tablespoonful of butter and a teaspoonful of vanilla. Remove from the fire and set in a pan of cold water until partly cooled, then add one-half cup of very finely chopped walnuts and beat until creamy. If the mixture hardens too soon set in a pan of hot water.

Mocha filling is made by creaming one-half cup of butter with one and one-half cups of confectioner's sugar, adding a pinch of salt. Beat in gradually one-fourth cup of strong coffee, two tablespoonfuls of melted chocolate, and a few drops of vanilla.

Everybody likes caramel goodies, so one would be safe in serving this filling: Cook together one cup of sugar and one-fourth cup of water until it spins a thread. While this is in progress, cook one-fourth cup of sugar in a saucepan until it starts to burn, add a tablespoonful or two of hot water and stir until dissolved, then add to the boiled syrup. Pour while hot over the beaten white of one egg, add some pecan nuts and spread between little squares of whole wheat bread.

Remember that the most successful sandwiches have their filling minced fine or mashed to a paste—never filled with coarse particles of food.

Far more effective than Sticky Fly Catchers. Clean to handle. Sold by Druggists and Grocers everywhere.

For Better Preserves

We have published a little book that is not only interesting, but helpful. It contains, besides a complete Section of "Hints for Canners," a large number of exceptionally good recipes which will be appreciated by housewives during the preserving season.

In the interests of the family health and for true economy "Can all the Fruit and Vegetables you can"; and to get best results in so doing, have a copy of this useful book before you.

In addition to these features, the book contains an explanation of the Perfect Seal Jar and other Jars made by us. Glass Jars are the only correct containers for canned goods, and those made by the DOMINION GLASS COMPANY are the highest grade obtainable.

For your Free Copy of this book, write

A WATER SYSTEM

Just to turn the faucet over the kitchen sink and draw all the water you need! Any housekeeper who knows that comfort after having had to carry water into the house by the pailful for years and years knows well there is no other labor-saving appliance that can surpass running water in the house. Generally it costs less to have this in any farm house than the farmer's wife expects. If there is a gasoline engine on the farm a trifling sum of money will be sufficient to pipe the water into the kitchen from an over-head tank.

MAKING ICE CREAM; FEW GOOD RECIPES

Ice cream can be made by cooking or without cooking the cream and sugar. It is easier to make it without cooking, and the cream is of a white and snowy texture, but cooking removes any possibility of curdling and gives the cream more richness. If the cream is cooked, put it in a double

Back at His Work in Quebec Woods

WILLIAM H. McDONALD SHOUTS PRAISES OF DODD'S KIDNEY PILLS

His Troubles Were Not Only Painful but Alarming Till He Found Relief in Dodd's Kidney Pills.

Bury, Que., July 20th (Special)—William H. McDonald, a young man living near here, is shouting the praises of Dodd's Kidney Pills. Rheumatism in his arms, severe pains in his back and head and an alarming pain in the region of his heart rendered him not only helpless but much alarmed as to the future. He found the relief he needed in one box of Dodd's Kidney Pills.

"I will recommend Dodd's Kidney Pills to anyone with weak kidneys," Mr. McDonald says in telling his story. "I am back at work in the woods feeling as well as ever. What with rheumatism and those pains in the head and near the heart, I was sick and anxious.

"But after a week's illness I tried Dodd's Kidney Pills. One box of them made me as well as ever I was in my life."

Rheumatism is caused by uric acid in the blood. If the kidneys are right they will strain the uric acid out of the blood. Rheumatism is caused by weak kidneys. The natural cure is to make the kidneys strong by using Dodd's Kidney Pills. Ask your neighbors about them.

Had Fainting Spells.

TOOK AWFUL FALLS.

Miss Eva P Yateman, Krugersdorf, Ont., writes.— 'I feel that I must write and tell you of the great benefit I have received from Milburn's Heart and Nerve Pills.

About three and a half years ago I was taken terribly bad with my heart, nerves and fainting spells, and was down in bed for about six months. I doctored with two different doctors and seemed to get better although the fainting spells would not leave me. I would take such terrible falls wherever I was that it was not safe to leave me alone at any time. At last I decided to resort to proprietary medicine and took several different kinds, but seemed to receive but little benefit from any of them. One day noticing the advertisement of Milburn's Heart and Nerve Pills, I decided to try them and before I had taken more than two boxes I could see they were helping me. I have taken about ten boxes and am almost cured of those terrible spells. I sincerely feel that your medicine has proved a blessing to me, and I would advise anyone troubled with their heart to try it as I am confident they will find relief.'

Milburn's Heart and Nerve Pills are 50c. a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

boiler, set it on the stove and stir often; take it off the stove when the water in the outer pan boils, add the flavors and sugar, stirring it until the sugar dissolves; let it stand a few minutes, strain, and put into the freezing can, and freeze.

If uncooked cream is used, it is well to whip a part of it, chill it, and stir it in just as the freezing cream is beginning to set.

Before beginning to freeze ice cream it should be allowed to stand in the freezing can, packed with ice, but covered only with gauze, until it is thoroughly chilled; if this is done it will freeze more readily and take less ice, and also, if not cooked, it is apt to become granular, or curdle, if attempt is made to freeze it right away, without first chilling.

Coarse salt must be used, the coarser the better. Fine table salt melts the ice too rapidly and is not suitable. Snow ice, which is full of airholes, is the best to use, being more readily penetrated by the salt. The ice should be broken into pieces no larger than a nut shell. Pack it into the freezer, add enough water to make it into a thick mush, and then put into the salt, in the proportion of 2 to 3 parts ice to 1 part salt. The water need not be drawn off until it floats the ice.

When newly frozen, ice cream is apt to be mushy, and lacks flavor and consistence, so that it is advisable to pack it down and let it ripen 4 or 5 hours before it is served. In packing it down, if it is to be kept thus for some time, pack in some ice, chopped coarser, and salt, and cover with some heavy material, an old piece of carpet for instance, and keep the covering wet.

Following are some good recipes which provide the different flavorings for ice cream:—

Fruit Ice Cream

Soft fruit, like raspberries or strawberries, should be mashed, sweetened, strained through a colander, if so preferred; this is not absolutely necessary, and stirred into the ice cream when partly frozen. Peaches, apricot, or such like fruit should be cut into small pieces, sugar added, allowed to stand until the sugar is dissolved, and then stirred into the cream when it is partly frozen.

Caramel Ice Cream

Until about three tablespoons of caramel for each quart of its cream. A little less sugar will be needed when caramel is used.

Chocolate Ice Cream

Use about four ounces of chocolate to each quart of ice cream; it should be mixed smooth in a little milk. A little vanilla is also added often, and a little cinnamon gives it spicy flavor; steep the cinnamon in warm water, and use the clear liquid for flavoring.

Philadelphia Ice Cream

Take one quart of rich cream, one heaping cup of sugar, and flavor to taste, and proceed as with other ice creams.

Almond Ice Cream

After blanching the almonds, pound them to a paste, adding a little rosewater to prevent their oiling; then add it as a flavor. Use about three ounces of almonds to the quart of ice cream.

Pineapple Ice Cream

To each quart of ice cream, allow one large pineapple; pare, slice, cut it very fine, lay it in a deep dish and sprinkle with sugar; cover the dish, and let it stand two or three hours; then strain through a sieve, mashing and pressing out all the juice; stir it gradually into the cream, beating well. A few slices of pineapple can be added, cut into dice, when the cream is partly frozen.

RELIEF AT LAST

I want to help you if you are suffering from bleeding, itching, blind or protruding Piles. I can tell you how, in your own home and without anyone's assistance, you can apply the best of all treatments.

PILES TREATED AT HOME

I promise to send you a FREE trial of the new absorption treatment, and references from your own locality if you will but write and ask. I assure you of immediate relief. Send no money, but tell others of this offer.

CARE OF HAIR BRUSH

It is impossible to overestimate the danger to the hair of unclean combs and brushes. Such toilet instruments should be carefully cleansed and disinfected once a week and there is a way to do it so as not to injure them. The brush and comb must first be quickly washed, then dipped in a water with boric acid and then sunned and aired. An expensively-backed brush may be cleansed by dipping the bristles alone in a strong solution of ammonia and water. After this, run hot and cold water alternately over this part of the brush, shake it vigorously, and put, bristles down, over a rest of some sort to dry in the open air.

If the bristles of the brush have lost their stiffness or elasticity, treat them to an ammonia and salt bath. First wash the bristles in hot water to which ammonia has been added, and then dip directly into water to which salt has been added. Dry the brush, with bristles up, in the open air.

Borax also cleans a brush well. Dissolve the borax in hot water and dip in the bristles. Rinse thoroughly, when clean, and dry, with ristles up, in open air. Combs can be cleaned with borax or ammonia, but ammonia sometimes discolors colored celluloid combs.

Another admirable method of cleaning brushes is to use dry bran. Naturally, this method is easier on the brushes. Rub the bran in thoroughly, as you would rub orris root into the hair, then shake and rub it out. It will take out all grease; bran can be safely used with brushes having bristles set in rubber, which cannot be cleaned with water.

LARD AND FRUIT PRESS

A very simple but handy device for pressing out lard, juices for jelly or fruit for marmalade, is made from two boards, each about 18 in. long, 3 in. wide and ½ in. thick, formed into the shape of paddles and hinged together. The hinge is made by running a wire through holes bored in one end of each of the paddles, and twisting the ends together. This presser is easily cleaned, and will save the hands from stains and other effects of the juices.

EMBROIDERING HANDKERCHIEFS

A woman who prides herself on her beautifully embroidered handkerchiefs has solved the difficulty of fastening the handkerchief in the embroidery hoop so that the corner may be easily worked. She bastes the corners of four handkerchiefs together, making one piece, which, when put into the hoop, brings the corners into the centre of the open space convenient for working. The same method may be followed when embroidering napkins.

A good bread to use for sandwiches.

1 cup scalded milk, 1 tablespoon lard, 1½ teaspoons salt, 6 cups sifted flour, 1 cup boiling water, 1 tablespoon butter, 1 yeast-cake, dissolved in ¼ cup lukewarm water.

To milk and water add shortening and salt; when lukewarm, add dissolved yeast-cake and flour, beat thoroughly, cover, and let rise until light. Add flour until dough is stiff enough to knead; knead thoroughly, let rise, shape in loaves, let rise again and bake.

RECIPES FOR RHUBARB

Rhubarb is not only one of the ever-ready and reliable early spring herbs, of which delightful desserts can be made, but it may be used to advantage from the canning storage cellar or the forcing plot during the winter.

The following recipes will prove to you just how good this herb can be made.

Baked Strawberries and Rhubarb

Place dried rhubarb, sugar and strawberries in layers in a baking-dish. Bake slowly in a moderate oven.

Rhubarb Fluff

1½ cupfuls rhubarb, 1 cupful water, ½ cupful sugar, 3 egg whites, ¼ teaspoonful lemon extract, 2 tablespoonfuls flour.

Cook rhubarb in water until tender, add sugar and flour mixed together and cook 5 minutes. Flavor and cool. Beat egg whites until stiff and fold rhubarb mixture into them. Put into glasses, heaping up in center. Pour around outer edge a custard sauce made as follows:

3 egg yolks, 2 tablespoonfuls sugar, ½ supful milk, ½ teaspoonful vanilla.

Rhubarb Tapioca Pudding

2 cupfuls rhubarb (diced) ½ cupful tapioca, 2 cupfuls water, ¼ teaspoonful salt, ½ cupful sugar, ¼ teaspoonful lemon extract.

Soak tapioca in cold water 4 hours. Cook in double boiler until transparent. Add salt, sugar, lemon extract and rhubarb and cook until rhubarb is tender. Serve with cream.

Pineapple Rhubarb Cream

½ envelope gelatin, ¼ cupful cold water, 1 cupful rhubarb, 1 cupful grated pineapple and juice, ½ cupful sugar, ½ cupful water, 1 cupful whipped cream.

Soak gelatin in cold water. Cook together the rhubarb, pineapple, sugar and ½ cupful water, and add to soaked gelatin. Set aside to cool. When it stiffens, add cream, beaten until stiff, and chill.

Rhubarb Strawberry Mold

½ envelope gelatin, ½ cupful cold water, ½ cupful boiling water, 1 cupful rhubarb, 1 cupful sugar, 3 eggs (whites), ½ cupful strawberry preserves.

Soak gelatin in cold water. Cook rhubarb in boiling water and sugar until tender. Add to soaked gelatin and stir until gelatin is all dissolved. Cool, and when it begins to set, add gradually to stiffly-beaten egg whites, beating mixture constantly. Add strawberry preserves, put in mold and chill.

Rhubarb and Raisin Tarts

1½ cupfuls rhubarb, diced, ½ cupful raisins (chopped) ½ teaspoonful candied orange peel (cut fine), ½ cupful sugar.

Roll pastry to ⅛-inch thickness; cut with biscuit-cutter; mix ingredients; place 1 teaspoonful in center of each piece; fold edges together: pierce top and bake.

GRASSHOPPERS IN THE WEST

(From the Saskatoon Phoenix

Western Canada is threatened by a visitation of grasshoppers. This, if not checked, can develop into a far-reaching and serious catastrophe. The plague has gained strength in Manitoba and has been reported in Southeastern Saskatchewan. Dr. A. E. Cameron, who is in Saskatoon at present, is taking steps to fight the grasshopper, btu the farmers of the Province must carefully co-operate with the authorities if this devouring pest is to be destroyed. In 1888, and earlier, Manitoba was overrun by grasshoppers, which literally consumed every green thing in their path, but the country has been fairly free of them since that time. The difficulty of securing arsenic with which to fight them is so great in Canada that it may become necessary to obtain a supply from the United States. Wherever grasshoppers appear in Saskatchewan reports should immediately be made to the university authorities and to the Dominion and Provincial Departments of Agriculture and no effort should be regarded as too great to check and obliterate this destructive visitation.

SOME OLD DATES

How many people know that if the old calendar makers speak truly, Cain killed Abel on the first Monday in April, which was Cain's birthday.

Superstitious people used to avoid this day for business transactions. In his Precepts to his son, William Lord Burghley wrote: "Though I think no day amisse to undertake any good enterprise or businesse in hande, yet have I observed some, and no meane clerks, very cautionaire to forbeare these three Mundayes in the yeare, which I leave to thine owne consideration, either to use or to refuse, viz: 1.—he first Monday in April, which day Cain was born, and his brother Abel slain. 2.—he second Munday in August, which day Sodome and Gomorrah were destroyed. 3.—The last Munday in December, which day Judas was born that betrayed our Saviour Christ."

Another recent Biblical anniversary which I'll wager not one in a million noted, occurred on March 17th. On this day Noah is said to have entered the Ark and he came out again on April 29th.

How the old calendar makers established all these precise dates is difficult to say. Perhaps, after all, some of them were only guesses.—The foregoing is from the London Answers.

HINTS FOR MOTORISTS

by ALBERT L. CLOUGH — Editor Motor Service Bureau Review of Reviews...

WHAT IS A "GAS KNOCK?"

There's Much Yet To Be Learned About Engines

When there is a knock in an engine and its cause cannot be attributed to carbon deposits, preignition, over advanced spark or mechanical derangement, it is often diagnosed as a "gas knock." Calling such a sound by this name is quite often a confession that the exact cause is not ascertained and so little is actually known as to precisely what happens in the gasoline engine cylinder, that no one need be ashamed to admit ignorance as to the origin of such disturbances. A great part of the "doings" of the gas and the engine is yet hardly more than theory, although it is talked of as if it were a settled fact. Things happening so inconceivably rapidly, in closed spaces are not readily followed or fully understood. An engine running on a weak mixture frequently "pounds" when working hard, at low speed and this is generally called a "gas knock." The origin of the sound is probably as follows: The weak mixture produces an effective pressure, so low in comparison with the resistance against which the engine si working, that during the power stroke, the moving parts pass from a condition of delivering useful work to that of receiving power from the flywheel and, if there is looseness in the bearings of such parts, there is a tendency for such looseness or "play" to be taken up first in one direction and then in the other—the striking together of the surfaces involved being the immediate cause of the pounding. A research recently reported to the Society of Automotive Engineers throws light upon another kind of "gas knock." It seems that the gasoline now in use has a habit of burning by stages. There is a combustion when the spark occurs, that may result in the breaking up of a portion of the fuel into compounds, which may then explode with very high pressure, detonate as it is called, if the temperature to which they are subjected is very high. It is these detonations, subsequent to the initial explosion and not self-ignition, that produce the knocks in many engines, that run hot and with too high compression. Pressure diagrams are shown that seem to demonstrate this detonating action. The research also tends to indicate that carbon deposits cause knocking not by causing self-ignition, but by increasing the compression anw combustion temperature to the point where detonating hydro-carbons are formed and fired.

COMPRESSION DATA

W. S. F. asks: (1) How do you figure the compression pressure in a motor-cylinder, (2) In a cylinder of 2½ inch bore and 3½ inch stroke, what should the clearance space be to give a gauge compression pressure of 90 pounds per square inch? (3) What degree of compression is ordinarily used and what is the highest that can be employed without causing preignition?

Answer: (1) The absolute compression pressure per square inch (gauge pressure plus 14.7 pounds), is equal to the absolute pressure at admission (14.7 pounds or less), multiplied into the compression ratio raised to 1.3 power. The compression ratio is the ratio of the clearance volume to the total volume above thee piston, when at its lowest point. A table of compression pressures is found in Heldt's "The Gasolint Automobile," p. 26, the use of which will eliminate calculations. (2) To obtain a compression pressure of 90 pounds per square inch gauge you will require a compression ratio of about 47.6. Your assumed cylinder will have a piston displacement of 17.18 cu. in. and the clearance volume should be about 4.56 cu. in. (3) Most engines carry lower pressures. Nninety pounds is safe only in small cylinders which are well cooled.

WEAK MIXTURE AND COLD INTAKE

W. W. A. asks: Why doesn't my car pick up better? It coughs, spits and sputters for a time, before it can handle the gas, when the throttle is first opened. Besides it does not seem to get kas enough, as I generally have to use the choker to get the desired power.

Answer: These symptoms indicate that the cylinders receivse weak mixture, that backfires into the carburetor occuh and the engine lacks power. Adjusting the carburetor for more gasoline, in proportion to air should relieve the situation, but we should not be surprised if the root of your trouble lay in the fact that your carburetor and intake are insufficiently heated to handle the present grade of fuel. The result of this condition is that the heavier constituents of the gasoline fail to vaporize, thus rendering the mixture leaner than it ought to be, considering the amount of fuel supplied. If you can apply exhaust heat to the intake system, we fancy that your engine will run properly upon your present carbuertor adjustment and more economically than it will if you open the gasoline adjustment to supply fuel.

Carhartt's Allovers

I FIGURE that when a man wears overalls he wants to be able to bend, twist or stoop freely without being conscious of them. So I purposely made my Carhartt's extra roomy, and double stitched every seam. The suspender buttons stick as if they were imbedded in concrete. Interlacing suspenders give you shoulder ease you never knew before —and they stay together in the wash, while the first grade denim cloth I use has a staunch durability that ensures a surprising length of service.

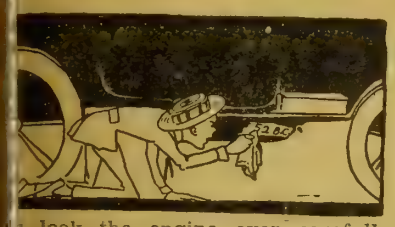
DRIVING OVER BAD ROADS

Th emtjority of motorists stick pret- close to city streets and country ghways that are at least somewhat iproved, but occasionally, through istake or intentionally they have to ive over very bad roads, such as tally neglected country byways, log- ng trails and even, in rare instances er fields. Here are a few sugges- ons applying to such unfavorable nditions: Drive at very low speed, ing middle or low-gear if necessary, r there may be rocks that will stone- uise the tires or cause such severe ocks as to break springs. There ay also be "bumps," perhaps hidden long grass. If sharp stones are countered, run over them, if pos- ble, with power shut off, as the cut- g effect on tires will then be less. ok out for stumps or rocks high ough to be struck by the car. Us- lly if the front axle will clear the st of the car will, but this not uni- rsally the case. Beware of spring les or wet places, where the wheels y sink and lose traction. Don't ist too much to the rude bridges d causeways found on neglected ads, for they may fall under the ight os a heavy touring car. As a neral rule, drive in the center of e road, following the ruts made by eceding vehicles, for the sides of ch roads are frequently soft and ish under heavy loads. Following ep ruts is, of course, hard on tires, t it is preferable to taking more rious chances. In turning out for ner vehicles, use special care on ac- unt of the danger of ditching.

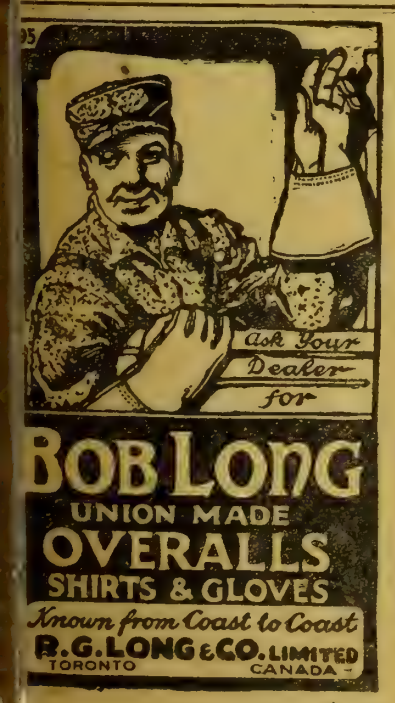
DETERMINING A CAR'S "VINTAGE"

F. M. W. writes: I am thinking of ying a used ——— car, that is said be a 1915 model, but there is some ubt in my mind as to what year it s built in. How can I find out pos- vely as to this?

Answer: The serial number it rs will tell when it was built. If



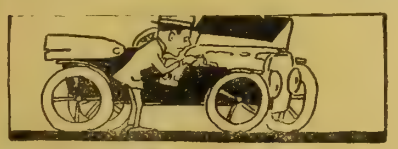
look the engine over carefully, ought to find a number stamped the metal, probably upon some t of the crank case. This number y be obscured by dirt and escape ir attention at first. When you find and submit it to any agent for this ke or to the manufacturer himself he should be able to give you the year immediately. In the case of many makes ther eare peculiarities of construction or equipment by which anyone familiar with the cars of this particular company, can tell you exactly when it was produced.



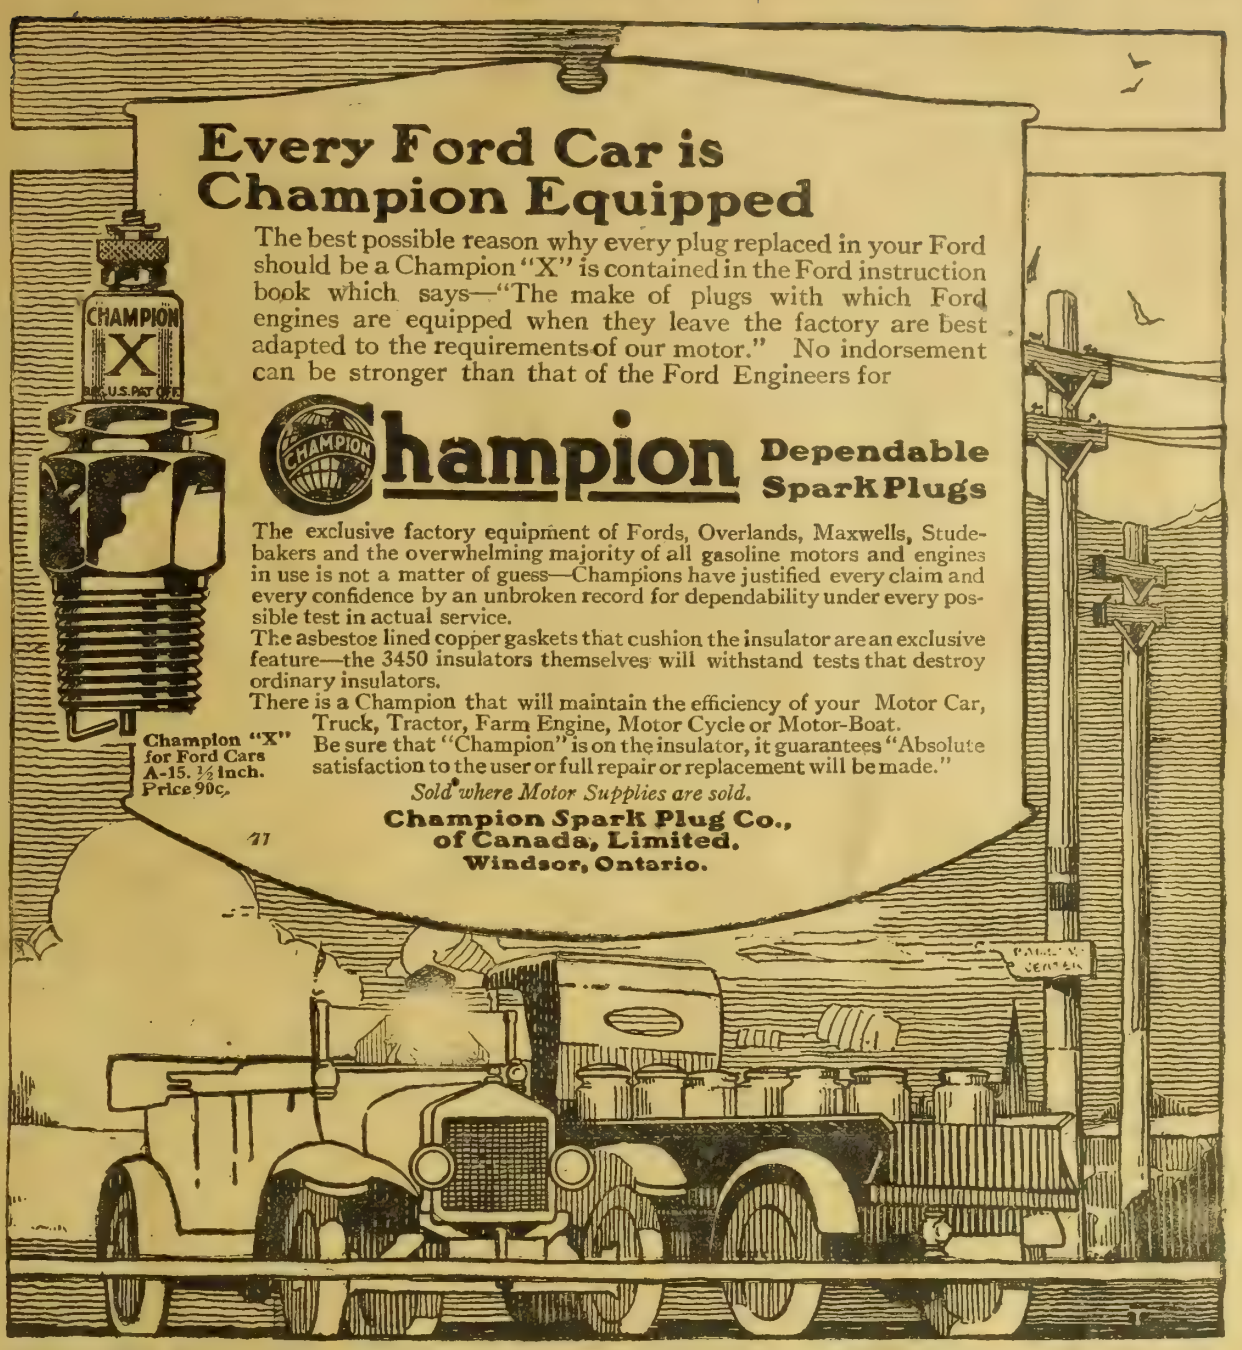
LUBRICATION OF MAGNETOS

T. W. L. asks What oiling does a magneto need?

Answer: As a rule, it only requires to have a few drops of light oil suplied to the two bearings of its armature shaft, once in each 500 miles or



so. There may be a few models which require ea drop of oil applied occasionally to the breakerbar bearings. You can obtain an instruction book from the maker of your magneto, which will inform you as to its lubrication requirements. Do not oil any other parts than those specified and keep all other parts free from oil and dirt. Oil tends to cause sluggish action in small, light parts which should work instantaneously and, when mixed with metal or carbon dust, may injure the insulation of the wire windings and cause short-circuits in the distrlbutor, that may result in interrupted or misdirected sparks. Too much oil aplied at the shaft bearings, may escape to other parts of the mechanism and cause trouble.



Every Ford Car is Champion Equipped
The best possible reason why every plug replaced in your Ford should be a Champion "X" is contained in the Ford instruction book which says—"The make of plugs with which Ford engines are equipped when they leave the factory are best adapted to the requirements of our motor." No indorsement can be stronger than that of the Ford Engineers for
Champion Dependable Spark Plugs
The exclusive factory equipment of Fords, Overlands, Maxwells, Studebakers and the overwhelming majority of all gasoline motors and engines in use is not a matter of guess—Champions have justified every claim and every confidence by an unbroken record for dependability under every possible test in actual service.
The asbestos lined copper gaskets that cushion the insulator are an exclusive feature—the 3450 insulators themselves will withstand tests that destroy ordinary insulators.
There is a Champion that will maintain the efficiency of your Motor Car, Truck, Tractor, Farm Engine, Motor Cycle or Motor-Boat.
Be sure that "Champion" is on the insulator, it guarantees "Absolute satisfaction to the user or full repair or replacement will be made."
Sold where Motor Supplies are sold.

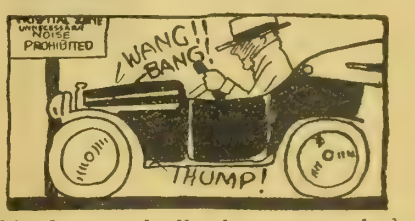
STARTER MOTOR FAILS TO ENGAGE

W. P. asks: What is the probable cause of my starter failing to turn the engine over? When I push the pedal, I hear a low humming but the engine does not move. There are teeth on the flywheel by which the engine should be set in motion.

Answer: It appears that your starter is of the type in which a pinion upon the electric motor shaft is caused to engage with the flywheel gear. Evidently this engagement does not take place. By watching the parts while someone else performs the starting operation you may find the trouble. In the starter drive in most common use the pinion is mounted upon a coarsely threaded sleeve upon the armature shaft and must move along the thread in order to engage the ring gear. If it turns with the threaded sleeve; it cannot move along it and sometimes dirt or grease upon the threads prevents it travelling into the engaging position. Sometimes also, through some abuse the screw threads become wedged in the pinion. If you find any such condition, free the pinion and wipe the thread perfectly clean and dry using kerosene to clean off all dirt and very likely you will not be troubled further.

ENGINE DEVELOPS HEAVY POUND

S. H. writes: I have lately had my car completely overhauled, the engine having been taken out and thoroughly gone over. After being put on the road again, it ran splendidly for several days and then I began to hear a slight pounding when the engine was running slowly and pulling heavily.



This has gradually become so bad that I am ashamed to operate the car. I have kept plenty of oil in the engine and do not see how a bearing could have burned out. Where should I look for this very heavy pound?

Answer: As you state that the engine has been dismounted from the chassis, it occurs to us as a possibility that, in replacing it, some of the bolts fastening it to the frame may not have been set up properly and have since gradually loosened, permitting the engine to vibrate upon its supports. If this hapens to be ean old engine with key-on flywheel, the wheel may have developed play on its shaft. If you find the engine fastenings all secure and the flywheel on

Auto Tires $17.50

Fine non-skid tire for small cars, size 30 x 3½, fully guaranteed for 3500 miles

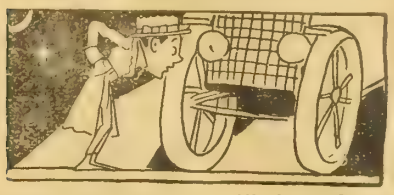
The Maritime Farmer begs to announce a substantial reduction in the price of non-skid tires for small cars, Fords, Chevrolets, Maxwells, etc. They are FIRSTS, fully guaranteed and we will sell them to you, provided you are a paid-up subscriber to the Maritime Farmer for $17.50 f. o. b. Sussex. Plain tires for $16.25, fully guaranteed for above mileage. Tubes for same size tire $2.90. These goods are all A1 stock and are made by a well known tire house. Of course these prices are for spot cash with order. The Maritime Farmer was able to take advantage of the recent break in the market and its large buying capacity to get you the benefit of this substantial cut in price. IT'S THE BEST BUY IN CANADA Today. Write the Auto Department, Maritime Farmer, Sussex, N. B.

tight, a loose crankshaft bearing is the most probable cause of the pound. Are you sure the cylinders are fast to the crank-case?

FORESTALLING SPRING BREAKAGE

L. E. W. writes: On my last trip, I broke a front spring, right at the center and had a hard time getting my car home. How can I guard against future breakage?

Answer: Avoid the use of springs with center bolts. The bolt hole constitutes a point of weakness. Take great pains to keep perfectly tight the clips that secure the spring to the axle. When this is done, the whole spring acts as a unit but, if it is not,



individual leaves are likely to be subjected to abnormal stresses, which they cannot sustain. Supply lubrication between the leaves. They necessarily slide one on the other when being deflected and, if this is prevented by their rusting together, excessive stresses are concentrated upon the outer ends of the leaves. Use a recoil strap or snubber to limit the recoil. While the chassis is moving downward the interleaf friction acts to limit the bending, but on the rebound, this friction is much reduced and under extreme conditions the leaves come largely out of contact, so that finally the upper leaf takes the whole stress and snaps. If a certain spring breaks more than once, it may be too weak for its purpose and another leaf should be added to it.

ELECTRICAL SHORT-CIRCUITS

Like People, Currents Seek "The Path of Least Resistance"

When, in an electric circuit, the current finds a path of flow that is shorter and "easier" than that which it was intended to follow and thus fails to pass through all the devices that it should operate, there is said to be a short-circuit. When flowing through a short-circuit or taking a "short cut," the current meets less obstruction (resistance) than its regular circuit offers and thus a greatly increased current may flow; so great in some instances, as to prevent other circuits from obtaining any current at all, to dangerously heat the wires through which it passes and to rapidly discharge the battery which supplies the electric system. The electrical devices, horn, lamps or ignition apparatus, in the deranged circuit, which are prevented from receiving current by the short-circuit, of course, fail to operate. Insulation, in the form of an air space, rubber, porcelain or some other material, is supposed to intervene between the two wires of a metallic circuit and between the single wire of a one wire circuit and the so-called "ground," which is the car frame, engine and other important metallic parts. When such insulation is abesnt, as by the chafing away of wire covering or by the coming into contact of metallic parts, a short-circuit is likely to occur. On some cars, each circuit is provided with a fuse, which melts and interrupts the current flow, when a short-circuit causes its volume to become abnormally large and others are fitted with automatic switches, which accomplish the same result. In the case of a car, so equipped, if the short-circuit is severe enough to cause the fuse or automatic circuit breaker to act it is at once apparent upon which circuit the trouble is, as the circuits usually all begin at a connection board, where the fuses or other protective devices are also located and the burned out fuse or the sprung circuit breaker is in the defective circuit. It then becomes necessary to locate the short-circuit and remove it. Suppose that one of the headlamp circuits is "shorted." If the battery is still charged and a test lamp is connected around the burned out fust, this lamp will remain lighted until the "short" is removed. With the test lamp lighted and the lighting switch "on," remove the head lamp bulb, remove its socket, move any loore parts of the wiring and generally examine the circuit. When the test lamp goes out, the "short" has been removed and, it only remains to restore the defective insualtion, the failure of which caused the trouble.

TROUBLE IN GEAR SHIFTING

A. F. asks: Why do the gears of my 1914-car shift so hard? The gears seem in first class condition and the cone-clutch appears to be in good order.

Answer: If it is merely that the operation of sliding the gears from one position to another is difficult, quite likely it is caused by lack of lubrication of the shifting mechanism. If you have the gearbox packed with hard grease, it sometimes happens that this collects around the outside of the case and leaves the working parts almost dry. If your trouble is that the gears cannot be brought into mesh without a great deal of clashing, the trouble probably is that the

clutch does not truly release and keeps the gears spinning or that the clutch brake, if one is used, does not stop the spinning of the clutch and gears as it ought to do. With the clutch and gears exposed to view and the lever in neutral, watch how the parts act, when the engine is running. If the clutch-cone and gears keeq on running, persistently, when the pedal is away forward, you will have to do something to stop this or clashing will result. Sometimes the use of a thick adhesive lubricant in the bearbox will tend to stop spinning, but you should have the clutch carefully examined to see if a cause for your trouble cannot be found there.

MARKETS.

Montreal, July 10—There was no further change in local prices for eggs today, but the undertone to the market continues strong under a steady increasing demand, and quite an active trade was reported in a wholesale jobbing way. There was also a good demand here for car lots of western eggs, and sales of seconds were made at 47c per dozen, f. o. b. Regina for shipment, and wires were received cancelling this figure for any more. The receipts today were 1,699 cases, as compared with 1,644 for the same day last week, and 737 for the corresponding date a year ago.

We quote wholesale jobbing prices as follows:

Strictly new laid eggs	00c to 60c
Selected stock	00c to 55c
No. 1 stock	00c to 50c
No. 2 stock	43c to 45c

A good steady trade continues to be done in dressed poultry for local consumption, and for shipment to outside points, and, in consequence, the market is fairly active, with no further change in prices to note. Supplies of fresh-killed and live poultry are steadily increasing and, in consequence, the demand for cold storage stock is not so keen as it was of late, but the movement of the latter is fair.

We quote wholesale prices of cold storage poultry, as follows:

Choice turkeys, per lb	48c to 50c
Milk-fed chickens	45c to 47c
Ordinary chickens	36c to 40c
Fowls, heavy	32c to 36c
Fowls, light	30c to 32c
Ducks, No. 1	45c to 48c
Ducks, No. 2	40c to 42c
Geese	30c to 31c

There were no further developments in the market for potatoes today, but the feeling is much better than it has been of late, and a fair trade in a wholesale jobbing way was done in old crop stock, with sales of good Green Mountains at $1.50, Quebec white stock at $1.25, and Manitoba stock at $1 per bag of 90 lbs. ex-store, while American new crop No. 1 Red Stars sold at $7, and No. 2 at $4 per barrel.

Chicago, July 18—Eggs, higher. Receipts, 20,138 cases. First, 41½c to 42c; ordinary firsts, 39c to 40c; at mark, cases included, 39½c to 41¼c; storage packed, firsts, 43½c to 44c.

New York, July 18.—Eggs, irregular. Receipts, 18,549 cases. Fresh gathered, extras, 51c to 53c; extra firsts, 47c to 50c; firsts, 43c to 46c; state, Pennsylvania and nearby western hennery, whites, fine to fancy, 58c to 62c; State, Pennsylvania and nearby hennery, whites, ordinary to prime, 45c to 58c; State, Pennsylvania asd nearby hennery, browns, 54c to 56c; do. gathered, browns and mixed colors, 50c to 53c.

CATTLE ACTIVE AT ADVANCED PRICES

July 18.—At the Montreal Stock Yards, West End Market, the receipts of live stock for the week ending July 12th, 1919, were 1,300 cattle, 1,700 sheep and lambs, 3,100 hogs, and 2,100 calves. The supply on the market today for sale consisted of 1,050 cattle, 1,400 sheep and lambs, 2,450 hogs, and 1,650 calves. Although the offerings of cattle were much larger than they have been of late the undertone to the market was stronger and prices were fully 25c to 50c per 100 lbs. higher than a week ago, which was due to the fact that frozen meat supplies have now been fairly well cleared out of the cold storage plants and, in consequence, there was a keener demand from packers for the best grades of cattle, which hesulted in a more active trade being done, and sales of straight loads of choice steers and heifers, weighing 1,150 to $1.200 lbs. each were made at $13.75 to $14.50, and good stock at $13.25 to $13.50, while choice lots of heavy cows sold at $12 to $12.50, and old ones of extra choice quality as high as $1[illegible] per 100 lbs. There was also a go[illegible] demand for the common grades [illegible] sales of bulls were made freely [illegible] from $6.50 to $8.50, and cows from [illegible] to $7 per 100 lbs.

The feature of the small meat tra[illegible] is the continued strong undertone [illegible] the market for hogs and, althou[illegible] prices showed no further advance [illegible] compared with those paid last We[illegible] nesday, the prospects were that th[illegible] would reach a still higher level in t[illegible] near future owing to the fact that s[illegible] plies throughout the country are fa[illegible] being depleted on account of the c[illegible] tinued keen demand from packe[illegible] The trade here today was brisk in [illegible] grades and sales of selected lots w[illegible] made freely at $24. extra heavies [illegible] $22 to $22.50, sows at $19, and st[illegible] at $17 per 100 lbs., weighed off c[illegible] Another feature of this market wa[illegible] the strength displayed in calves a[illegible] prices for good to choice lots ha[illegible] scored a sharp advance on accou[illegible] of the active demand for such and [illegible] somewhat limited offerings. Sales o[illegible] choice lots were made at $15 to $[illegible] good at [illegible] grades at from $7 to $10 per 100 l[illegible] In addition to the demand for ca[illegible] for local consumption, there is a[illegible] [illegible] shipment to the United States on [illegible] count of the much higher prices [illegible] ing in that market as compared w[illegible] those here. There was no furt[illegible] change in the condition of the mar[illegible] for lambs, but the undertone is e[illegible] on account of the fact that supp[illegible] coming forward are in excess of [illegible] local requirements, and there is no [illegible] mand from outside sources for t[illegible] at present. Sales of choice lots of [illegible] tario stock were made at $17 to $[illegible] and Quebec at $15 to $16 per 100 [illegible] The trade in sheep was qui[illegible] prices ruled easier at $7 to $9 per [illegible] lbs., as to quality.

At the Canadian Pacific Live St[illegible] Market the receipts for the w[illegible] ending July 12th were 700 cattle, 1[illegible] sheep and lambs, 1,850 hogs, and 1.[illegible] calves, while the offerings on the ma[illegible] ket today for sale amounted to 1.[illegible] cattle, 800 sheep and lambs, 1,300 h[illegible] and 700 calves. The trade in all line[illegible] at this market was also active, ther[illegible] being a good demand for supplies an[illegible] the tone of the market for cattle an[illegible] hogs was strong and calves sold [illegible] higher figures.

We quote prices as follows:

Steers, per 100 lbs.—		
Choice	$13.75 to	$14.[illegible]
Good	13.25 to	13.[illegible]
Fairly good	12.75 to	13.[illegible]
Fair	12.25 to	12.[illegible]
Medium	11.75 to	12.[illegible]
Light	11.00 to	11.[illegible]
Common	8.50 to	10.[illegible]
Cows—		
Choice, heavy	12.00 to	12.[illegible]
Choice, light	11.50 to	11.[illegible]
Good	11.00 to	11.[illegible]
Fair	10.50 to	10.[illegible]
Medium	9.00 to	10.[illegible]
Common	7.50 to	8.[illegible]
Canners	5.00 to	9.[illegible]
Bulls—		
Choice, heavy	11.50 to	12.[illegible]
Choice, light	11.00 to	11.[illegible]
Good	10.50 to	10.[illegible]
Fair	10.00 to	10.[illegible]
Medium	9.50 to	9.[illegible]
Common	8.50 to	9.[illegible]
Canners	6.50 to	7.[illegible]
Hogs—		
Selects	00.00 to	24.[illegible]
Heavies	00.00 to	22.[illegible]
Extra heavy	00.00 to	21.[illegible]
Sows	00.00 to	19.[illegible]
Stags	00.00 to	17.[illegible]

ANOTHER ADVANCE IN BUTTE[illegible] PRICES

Montreal, July 18.—The receipts [illegible] butter today were 722 packages, [illegible] compared with 3,341 for the same da[illegible] last week, and 354 for the correspon[illegible] ing date a year ago. In sympath[illegible] with the higher prices paid in th[illegible] country for creamery butter on Satu[illegible] day and the keener competition b[illegible] tween buyers for the offerings he[illegible]

today at the auction sale prices were advanced ⅞c to 1c per lb. as compared with those paid last Friday. On account of the above a stronger feeling developed in the open market and prices were also marked up with an increased demand for supplies, and a fair amount of business was done. In a jobbing way a steady trade was reported in finest creamery in 54c per lb. in solid packages, and at 55c in 1-lb. blocks, but these prices will be advanced 1c per lb. on Tuesday.

We quote wholesale jobbing prices as follows:

Pasteurized creamery...54½c to 54¾c
Finest creamery.....53½c to 53¾c
Fine creamery.....53c to 53¼c
Finest dairy.....48c to 49c

The receipts of cheese today were 9,510 boxes, as against 11,925 for the same day last week, and 8,940 for the corresponding date a year ago. The export of cheese for the week ending July 12th, were the largest of any previous week so far this season, there being 106,821 boxes shipped, which shows an increase of 2,561 boxes as compared with last week. There was no further change in prices for cheese at the auction sale held today owing to the fact that the demand for the offerings was entirely from the local packing concerns, exporters not being in the market.

MILLFEED AND ROLLED OATS

Montreal, July 18.—There was no change in the condition of the market for millfeed, prices being firm, with a steady trade passing for the season of the year in most lines, and sales of broken lots of bran in mixed cars were made at $43 to $43.50, shorts at $45.50 to $46, pure barley meal and mixed grain moullie at $62 to $64, mixed moullie at $56 to $58, dairy feed at $48, and oat middlings at $44 per ton, including bags, delivered to the trade, while car lots of bran were quoted at $42, and shorts at $44 per ton, including bags, ex-track. On account of the strength displayed in the market for oats of late a stronger feeling has developed in the market for rolled oats, and prices have been advanced, with sales of standard grades to wholesale dealers at $4.50 per bag of 90 lbs., and to retail dealers at $4.75, delivered to the trade. There was no change in cornmeal prices, but they are very firm at $5.25 to $5.35 per bag.

THE BALED HAY MARKET

Montreal, July 19.—There were no new developments in the market for baled hay, but the feeling continues easy on account of the fact that supplies coming forward are ample to meet all immediate requirements, and the prospects are for a bumper crop, which is a bearish factor. The trade is fair, with sales of car lots of good No. 2 timothy hay at $30, No. 3 timothy hay at $28 and clover and clover mixed hay at $25 per ton, ex-track.

Utica, N. Y., July 14.—At the session of the Utica Dairy Board of Trade today, the total sales of cheese were 2,490 boxes, all selling at 30½c.

New York, July 14.—Butter, steady. Receipts, 15,314 tubs. Creamery, higher than extras, 54¼c to 55c; creamery, extras, 92 score, 53½c to 54c; firsts, 51c to 53c; packing stock, current make, No. 2, 45c. Cheese, firm. Receipts, 3,211 boxes. State, whole milk, flats, current make, specials, 32¼c to 32¾c; average run, 31¼c to 32c; State, whole milk, twins, current make, specials, 32¾c; average run, 31¾c.

Belleville, July 14.—At the regular meeting of the Cheese Board 595 boxes of white were offered. All sold at 29c.

CLOVER SOD BEST FOR GOOD CORN CROP

Ideal soil conditions for the corn crop are represented by a well-drained, medium loam plentifully provided with decayed vegetable matter (humus). That the successful growth of corn is closeyl associated with abundant soil humus will be clearly apparent on a brief consideration of its functions as related to the needs of corn.

Humus is the most important soil constituent and imparts that highly desirable, mellow physical condition, denoting warmth and life, to both light (sandy) and heavy (clay) soils. The practice of manuring is based on this fact. Humus is the medium which supports the favorable bacterial life of the soil and is the chief source of the valuable nitrogen which these organisms release—along with the mineral constituents of humus—for the nourishment of the growing crop. Furthermore, the acids produced during the decomposition of humus exert a solvent action on the mineral soil compounds, liberating phosphoric acid, potash, etc., in assimilable forms. Humus acts like a sponge absorbing and retaining moisture; it is the upper-soil reservoir of water which it yields up gradually to the feeding roots and will thus enable a corn crop to withstand or more rapidly recover from the effect of a prolonged period of drought.

For its favorable germination, corn demands a warm seed bed, and to lack of this essential condition many failures are due. Corn makes a rapid, succulent growth and—like all leafy crops—imbibes and transpires water freely, requiring therewith a bountiful supply of nitrogen and mineral for the building up of its tissues.

A good crop of red clover (cut for hay) is an ideal forerunner of corn; the decaying residues of clover stems, leaves and roots furnish a large amount of humus rich in nitrogen. Clover, alfalfa and other legumes possess the unique faculty of assimilating atmospheric nitrogen and thus of enriching the soil in that valuable element. Furthermore, their deeply ramifying roots draw mineral plant food, in solution, from the subsoil, and, in their subsequent decay, liberate this mineral matter in zones accessible to the roots of corn.

A sod carrying a heavy aftermath of clover or alfalfa may furnish such an abundance of humus-forming material as to dispense with the necessity for the addition of barnyard manure.

According to experiments conducted at the Central Experimental Farm, a vigorous crop of clover contains, in its foliage and roots, from 100 to 150 pounds of nitrogen, 30 to 40 pounds of phosphoric acid, and 85 to 115 pounds of potash per acre—approximately equal, in fertilizing value, to ten tons of good barnyard manure. Further investigations showed that the roots, dead stems and leaves (the clover residues ordinarily remaining after removing the crop), collected immediately before spring ploughing, contained from 60 to 80 pounds of nitrogen, 20 to 30 pounds of phosphoric acid, and 50 to 70 pounds of potash per acre or the approximate equivalent, in fertilizing value, of six tons of the best barnyard manure.

THE IMPROVEMENT OF TOMATOES BY SELECTION

Importance of good seed.—In all northern districts, where the season is barely long enough for a heat-loving plant such as the tomato, trueness to name is a very important consideration, because most fruits will not mature and the grower will lose his time if, accidentally or otherwise, seed of a late variety is sold for that of an early one.

Some commercial seed unreliable—A great many of the best growers now save their own seed, as they know that there are large quantities on the market which come from canning and catsup factories where it is cheaply separated by machines. The mere fact that most seedsmen will not guarantee what they sell shows that the commercial article cannot very well be relied upon.

What to select for—First of all, it must be remembered that tomatoes cross, so that only one variety can be grown. Theoretically, a person should select tomatoes for extreme earliness, great productiveness, bright red colour, large size and high quality. But, as there is no such thing as an all-round perfect strain, it is better, in practice, to breed for one thing at a time. It is also no use to work for contradictory attributes; for instance, when the size of fruits is larger there are generally fewer in a cluster, though the total yield may be greater.

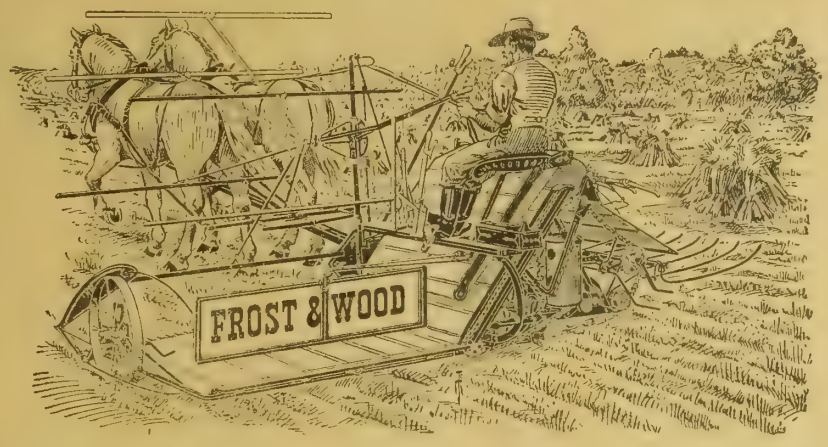
Plant and not fruit is the unit.—It should always be remembered that attention must be directed towards the whole plant and not only to a part of it. Thus, it is a mistake, in selecting for earliness, to save seed from a plant which bore one very early fruit whilst the others were rather late in maturing; what should be done is to save seed from a plant having the largest number of fruits maturing early enough for tre locality where grown.

Work Done at Cap Rouge.—A few strains were isolated at Cap Rouge, for yield, in certain cases, and for earliness, in others. A selection of Prosperity from Bolgiano 1914 stock produced 20% more in 1917, after three years' work, than seed bought from this firm that year; a selection of "Sunnybrook" Earliana from Burpee 1914 stock produced 46% more in 1917, after three years' work, than seed bought from this firm that year; a selection of Danish Export from Wiboltt 1914 stock matured fruit in 135 days, in 1915, whilst seed from this firm took 140 days; a selection of Bonney Best from Harris 1911 stock matured fruit in 163 days, in 1913, whilst seed from this firm took 167 days.

Free distribution to interested parties.—Strains of Earliana have been specially selected at the Experimental Station, Cap Rouge, Que., since 1911, and a limited quantity of choice seed is distributed free to interested parties who apply to the undersigned.—Gus. Langelier, Supt. Experimental Station, Cap Rouge, Que.

It Guarantees the Harvest

You have only a few precious days in which to cut and stock your crop so your whole year's work may well depend on the reliability of your Binder. That's why wise farmers buy the



FROST & WOOD BINDER

It has won a reputation, during many years, and under all kinds of Canadian crop conditions as "the Binder that is always ready—and able to get ALL the crop." It's "ready" because its simple, superior scientific design and its high grade materials keep it out of the repair shop—and it "gets all the crop" because it is so easy to operate that fast, clean work is always possible with it.

LIGHT DRAFT - SURE CUTTING AND TYING - DEPENDABILITY

Its big power wheel and strongly braced steel frame ensure ample strength—high grade roller bearings at all friction points ensure light draft—a wide range of adjustments of the reel ensures that any crop, heavy or light, lodged or straight, is easily handled. Big capacity elevators and positive binding attachment, all show the hand of the master designer. Get a Frost & Wood Binder Booklet from our nearest agent—and see the Binder itself—you'll see why it "Guarantees the Harvest."

THE FROST & WOOD COMPANY, LIMITED

Truro, N. S. ST. JOHN, N. B. Charlottetown, P. E. I.

WHEN BALKY HORSE FORGETS THE HABIT

I would like some information regarding the training of a balky horse. At times my horse is eager to go, but at other times she will throw her head from side to side and not start.

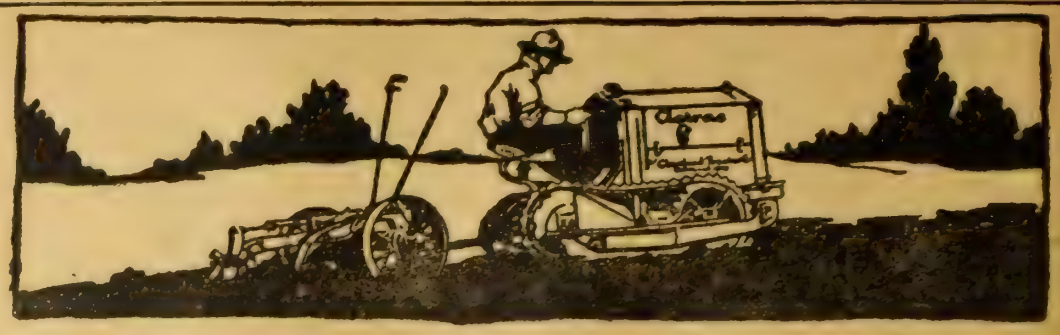
There is no sure cure for a balky horse, and one which has acquired the habit to a bad degree will likely never get over it. A balky horse should never be overloaded and the harness should always be properly fitted. The horse also should not be expected to work too long. The only way to overcome the balkiness is to give the animal no reason to balk for a long period of time, in which case he may entirely forget the bad habit. Various humane and inhunmane devices are practiced in getting a balky horse to move. We believe that none of the inhumane devices should be used. A balky horse will often start if the driver stops and readjusts the harness, picks up the feet or performs any other little act which is likely to distract the animial's attention and make him think that the driver is not acquainted with his cause for stopping.

WHAT'S A PEDIGREE?

Peedigree is a record showing the animals that have in succession entered into the breeding of the individual. It shows, too, that the animal belongs to a distinct breed, possessing, therefore, the prepotency of that breed, and in addition to this possession it guaranteees a certain degree of individual prepotency dependent upon the excellence and known prepotency of the ancestors on each side of the pedigreee. To insure both breed — prepotency and indiividual prepotency—the animal should have several recorded animals upon the dam's side, and the more and better the more certain will be the good breeding qualifications of the pedigreed animal.

The sires should be of equal merit, and the most important point is to see that they are of known purity of blood and individual excellence; also that upon neither side is there an objectionable outcross or the presence of a sire or dam noted for unsoundness or other objectionable trait, character or feature. Furthermore the character of the man back of the pedigree should be taken into account. The pedigree is comparatively valueless unless the breeder and seller are noted for integrity; nor is a pedigree a sufficient criterion of merit or an apology for individual imperfection or unsoundness. The animal should be a good individual, and if, in adition, there is a long line of excellent ancestors upon both sides of its pedigree, there will be good reason to expect that it will, with considerable fidelity, transmiit to its progeny the true characteristics of its breed, those of its family and those of its individuality.

In some instances an individual with a long line of reputable ancestors is itself a comparatively poor individual, yet may prove an impressive sire, or dam, and, on general principles, the somewhat different individual that has a fine line of ancestors, as shown by its pedigree, is greatly to be preferred to a scrub, grade or cross-bred animal for breeding purposes. We say this for the good reason that the progeny will be likely to partake of the good qualities of the ancestry rather than the indifferent qualities of the individual. There are many exceptions to this rule, and experiment is, therefore, the sure way of proving the prepotency of the individual. It is always best, however, to choose an animal that has both excellent breeding and individual excellence of form and quality in every respect.—S. Alexander, V.S.



An Acre an Hour

From every part of Canada come letters of praise for the Cletrac Tank-type Tractor.

Here is the experience of Wesley Walden, of Lindsay, Ont.

In direct competition with his two sons, each with a three-horse team, he plowed two acres to their one.

Plowed when all neighbors had stopped because of rain.

Never mired the Cletrac in the softest ground.

Fits his seed-beds without a horse.

Uses his Cletrac right through harvest and winter.

He says, "I have my farms in the best shape I ever had them, thanks to the Cletrac Tractor."

You should know more about this economical, powerful, 100% useful farm machine. The Cletrac dealer, or we ourselves, will be glad to send you our book, "Our Owners Say," containing Mr. Walden's letter and many others. Write for it to-day.

The Cleveland Tractor Co. of Canada
Windsor, Ont. **Limited**

Digby, N.S.

Cyrus & Manning Ells, Port Williams, N.S.

Gentlemen,—I take great pleasure in answering your letter of the 20th re Cletrac Tank-type Tractor. I have one, and in fact the first one in the Province. It was demonstrated at Truro in competition with the ——— Tractor, and I had the privilege of buying either one or both, but decided on the Cletrac. We have been called upon to give more demonstrations with this machine than anything else I ever owned. To my mind, it is as much ahead of the ——— Tractor, as the ——— car is ahead of the ——— car.

The Cleveland makers are the best people to give service of any concern I know of putting out machinery. This of itself is a strong incentive to one buying. There are many things you can do with a Cletrac, that you cannot do with a ———. It has the best running motor you ever saw.

While I am holding out some strong inducements for the Cletrac do not think I am interested in any way.

If I have omitted any information you would like to have, I would be glad to communicate with you further.

Yours truly,

(Signed) H. T. Warne.

Cletrac
TANK-TYPE TRACTOR

R. O. P. STANDARD HAS CHANGED NEW AMOUNTS REQUIRED IN ORDER TO QUALIFY FOR A CERTIFICATE

At the last annual meeting of the Holstein-Frieisian Association a motion was passed to raise the standard of qualification in the Record of Performance to at least 400 pounds of fat for a mature cow, with the same rate of increase between the standard for a two-year-old and a mature cow as under the former rules The original rules provided for a daily increase in the amount of fat required of .0931 pounds and of milk 2.75 pounds with a standard fat percentage of 3.40. In other words, a four-year-old was required to produce 34 pounds less fat than a mature cow, a three-year-old 34 pounds less than a four-year-old, and a two-year-old 34 pounds less than a three-year-old. Retaining the same ratio of increase in fat and milk, and keeping the standard percentage of fat at 3.40, it was found advisable that the yearly production of milk be maintained in round numbers for convenience in calculation. Accordingly all cows entered in the Record of Performance after April 30, 1919, will be required to reach both the following amounts in order to qualify for a certificate.

Class	Milk lbs.	Fat lbs.
Mature	12,000	408
Four-year-old	11,000	374
Three-year-old	10,000	340
Two-year-old	9,000	306

WHY SOME FAVOR WINTER DAIRYING

When the cows freshen in the winter there is more time for milking and caring for the calves. The milk brings the best price and the income is often needed more during the winter than in the summer when more money is constantly coming in for the varied crops and produce that can be sold. On some farms there is a steady income from produce from the time the asparagus and early truck are sold until the last apple is picked in the fall. From November 1 until April the income from a few dairy cows is much appreciated and it has often brought a family many pleasures which would have been impossible if it were not for the money received from the cows.

MILK PRICES IN SCOTLAND

Fixed prices and some measure of control still exist in Scotland in regard to the sale and distribution of milk. The prices for the five months —May to September—have now been announced, and they work out at an average of 36c per gallon. This price is regarded as moderately satisfactory. The prices could not be made further ahead than September, pending the determination of future policy in respect of control. One cent a gallon less is paid the farmer who delivers the milk without it being cooled.

The reason for giving a bigger price for August and September is obvious. It wil ltend to encourage the fixing up of such arangements as will provide for a greater flow of milk for the winter months.

CREAM COOLING TANKS

We like the idea in Iowa, as expressed in the "Cream Improvement oCntest" and carried on by the Buttermakers Association of that State. One hundred dolars was voted by the Association as a "starter" for the fund. The main points are expressed in a scale—"15 points for a milk-house; 10 points for cooling tank; and 10 points for moving the separator from unsanitary to sanitary places." It is claimed, "the cooling tank will eliminate practically all cellar or food flavors." How would it do to inaugurate a cooling-tank campaign among the patrons of Canadian creameries for the season of 1919?—H. H. D.

The dairy cow has a nervous temperament which is eeasily disturbed by unusual onises in the barn such as barking dogs or unnecessary shouting among men. It pays to be quiet around the cattle, as everything disturbing them helps to reduce the milk flow and cuts down the dafry products.

Whether or not a man can make his dairy pay depends wholly upon the attention he pays to the cows.

Now comes an inventive chap who says that the vacuum cleaner is just the thing when a thorough horse cleaning is desired. Whoa there, Dobbin!

OILING THE AUTO

Correct lubrication of a car has perhaps more to do with its long life and successful operation than any other thing. eRpairmen will often tell you that many of the motor ills are due to improper or insufficient lubrication that might have been prevented had a study been made of the oiling chart and the oil applied and renewed at regular periods.

It is an excellent plan to change the oil in the motor several times during th eseason. Constant use at a very high temperature causes the oil to become too thin for correct lubrication. Friction causes minute particles of metal to be broken or worn off and the old oil contains this injurious material. The oil in the crank case should be drained and a gallon or so of kerosene put in the rersevoir. The motor should now be run slowly for three or four minutes thoroughly flushing the motor. The kerosene when drained off will be very black showing the impurities it contains. The fresh oil that you put in will stay clear and clean for some time.

Your oiling chart will tell you which parts require lubrication every 100, 500 or 1000 miles. These instructions should be carefully carried out in order to prevent friction and prevent avoidable wear. The grease cups should be carefully cleaned off when filled so that no dust or dirt gets in the grease or the greasing will do little good. Always see that the motor is well supplied with lubricating oil. The absence of oil may cause the motor to overheat or even stop.

Only the best oils and greases should be used in a car. Cheap oil may not be able to withstand the high temperature and become too thin to lubricate well. Also poor oil may break up under the heat and cause carbo ndeposits thus causing motor trouble. The best greases are necessary to prevent wearing the gears in the transmission and the rear axle. Graphite or a mixture of graphite and oil can be used on the springs when needed.

For the magneto several drops of the highest grade sewing machine oil would be suitable. It should be applied one or twice a month. The clutch, fan and parts that are in continual use will require attention frequently.

If the car owner desires his car to be long lived and run smoothly and quietly it will pay him to study the oiling diagram for his car and follow the instructions carefully.

CUTWORMS

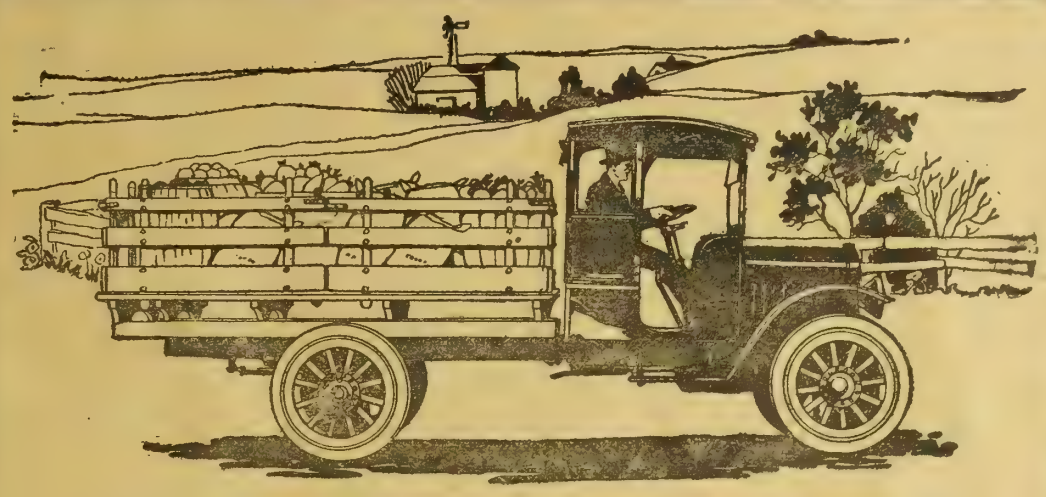
By A. J. Gorham, B. Sc.

Cutworms are doing a great deal of damage this year, to corn, cabbage, beans and other crops. These pests do their destructive work at night. They are the larvae of Owlet-moths. There are a great many different kinds of cutworms. Their life history is as follows: The moths lay their eggs during mid-summer. The larvae soon hatch, and feed upon the roots and tender shoots of herbaccous plants. At this time, as the larvae are small and their food is abundant, they are rarely observed. On the approach of cold weather they bury themselves in the ground and there pass the winter. In the spring the renew their attack on vegetation. But now as they are larger and in cultivated fields the plants are smaller, their ravages quickly attract attention. They have the unfortunate habit of cutting off the young plants at the surface of the ground and thus destroy much more than they consume.

Remedies: Poisoned baits of fresh clover or other green vegetation. Probably the best remedy is Poisoned Bran Mash. Take ten pounds bran, add enough water to make soft mash, spread out on table in thin layer, sprinkle on this about three ounces of Paris Green, add this in small lots, spreading out, mixing and re-mixing until all the poison is thoroughly distributed through teh bran mash. To this may be added a little molasses and the juice of a lemon or orange. This makes it more tasty.

Toward evening sprinkle this mash along the rows or around the plant. Look for dead cutworms in morning.

The 2temptation is great on the farm to get just as much work out of the brood mare whe she has a foal as is possible, and is all right to do so if the owner uses just a little bit of judgment when to let the foal suckle and when not to do so.



This Maxwell Truck Will Give You More Land More Money, More Time

A MAXWELL truck will go farther, do more than six good horses—in less time. And it costs no more. It feeds only when it earns. It defies weather. It is always on the job—ready to haul anything from 50 bushels of grain to 3,000 pounds of potatoes—anywhere, any distance.

It takes 5 acres to feed a good horse. Thirty acres to feed 6 horses. The wheat you can raise on 30 acres of land will pay for a Maxwell Truck—now.

Those 30 acres are then free to make money for you. And your Maxwell Truck will make money for you. It will enable you to market your crop quickly—in the best market—at the best price.

It will save you hours—days—of valuable time. It will make your work easier, pleasanter, more profitable.

Travels faster than heavier trucks. Yet it is big enough to handle 90 per cent of all hauling jobs.

Has the same type of worm drive which $7,000 trucks advertise as their great feature. $7,000 truck construction and sold with a $7,000 truck guarantee. 10-foot loading space. Power enough to pull a wagon when truck and wagon are fully loaded. Electric lights and generator. Chassis $1,550, f.o.b. Windsor, Ont.

See your nearest dealer. If you don't know him write and we'll tell you.

P.S.—You can get Maxwell service wherever you are.

New Mines - - - N. S.

TILE-DRAIN YOUR LAND. IT PAYS

On the Illustration Station at Stanbridge East, which Station is owned and operated by Mr. Charles S. Moore, very interesting and profitable results have been obtained. At this Station, two four-year rotations are being carried out, one on land which is fairly well tile-drained, teh other on land odjoining, with good surface drainage, only narrow lands being ploughed and the furrows kept clear. The soil is similar in character on both areas.

In 1918, Banner oats were sown on both fields. Those sown on the tile-drained land were sown much earlier than those on the undrained land and yielded 55 bushels per acre, costing 36¾c per bushel.

The surface drained land could not be worked nor sown until several days later and yielded 21 bushels per acre, costing 74¾c per bushel, a difference of 34 bushels per acre. The highest yield is low compared to what may be expected after the drained land is cultivated a few times and the drains have been working to the best advantage.

Results

The tile-drained laid yielded 55 bu. per acre, costing	$20.21
If sold at $1.00 per bus	55.00
Balance, profit	$34.79
The undrained land yielded 21 bushels per acre, costing	$15.70
If sold at $1.00 per bushels	21.00
Balance, profit	$5.30
It will here be seen that tile-drained land gave a greater profit of	$29.49

A good time to put in tile drains is as soon as the hay harvest is over.

JOHN FIXTER,
Division of Illustration Stations,
Central Experimental Farm,
Ottawa, Ont.

A VERY VALUABLE BOOK

The Veterinarian, by Charles J. Korinck, V. S., is a work on the afflictions of horses, cattle, sheep, swine, poultry, etc., which every farmer should have in his home. The story of how treatment can best be administered is told in simple every-day English that any person can understand. The methods suggested by Prof. Korinek are simple and easily followed. The book will cost you seventy-five cents, postage paid. It may be the means of saving you as many dollars in the near future. How many men are there who meet trouble by writing to the Maritime Farmer or some other paper for information which will be found in the Veterinarian? It is strongly bound in cloth, has serviceable illustrations and is well indexed. Seventy-five cents will bring it to you.

Chester White Pigs for Sale

Spray Pink and Green Potato Aphids

Aphids are Capable of Very Rapid reproduction---Rose Bushes are Host Plants--How to Make and Apply Spray

By Edith M. Patch, Entomologist, Maine Agricultural Experiment Station

The Green Potato Aphid has been doing considerable damage to the potato crop in Maine durinig the last two or three years and has been gaining a foothold in New Brunswicw. Our readers will be interested in the following article from the columns of the Potato Magazine, the official organ of the Potato Association of America:

Throught wide publicity given, for economic reasons, to the "white pine blister disease" and "the black stem rust of wheat" we are all familiar with the fact that the one migrates between white pine and currants or gooseberries and the other between the common barberry and certain grains. That the life cycles of many aphids include an alternated diet with reference to different stages of their development which is comparable to that of such fungius diseases is, perhaps, not so well knonw.

The migratory habits of many of our most serious pests among the plantlice, however, have to be taken into consideration with refernce to an understanding of their economic status; for it sometimes happens that a species con be controlled on one plant and thus its attack on the alternate food plant prevented. Or, on the other hand, this same habit of migration may double the difficulties in handling the situation.

The pink and green aphid of potato, which seriously infested fields all the way from the Atlantic coast to the Mississippi valley in 1917 and 1918, is a migrant species.

This insect passees the winter in the egg on rose bushes. The aphid which hatches from the egg in the spring is commonly spoken of as the "stem mother," a wingless form which upon maturity, gives birth to living young, the egg being represented but once in the many generations of the annual life cycle of the species—that is the hibernating stage already mentioned. The progeny of the stem mother are all females which in turn give birth to female generations. Most of these consiist of part winged and part wingles sindividuals. During the spring these develop upon the tender shoots and leaves of the rose, both wild and cultivated varietiies.

Watch Now for Aphids

About the middle of July in Northern Maine, a few scattered aphids may be found upon the potato vines which previous to that time were uninfested. These are the first of the migrants to appear on this plant and are fully mature and ready to produce young. In Connecticut this migration occurs at least a full month earlier and it is recorded for southwestern Ohio early in June.

These first individuals to settle upon the potatoes in small numbers here and there are an inconspicuous factor in the history of the infestation. These little objects, measuring approximately ⅛ of an inch, seeking the under surface of the leaf or resting quietly upon the tender growing shoots, would neitiher by their presence nor the direct injury they do be anything to distrub the most watchful potato grower. But though these migrants are inconspicuous and the amount of sap they drink inconsiderable, they are not for all that an insignificant item in the season's potato crop. To illustrate, an observation made in Ohio might be cited. A single aphid this species was caged on an uninfested plant, and at the end of 12 days her progeny (daughters and granddaughters) totaled 76, five of which were already producing young, it requiring under Ohio climatic conditions only about 10 days for one of these females to become full grown and begin producing.

The pink and green aphid is a restless species, the females upon becoming mature showing a marked tendency to move from the plant on which they developed to stems not yet crowded with the pest and in healthier condition, before establishing their colonies of young. Both the winged and wingless forms exhibit this habit so that, by dispersal, the area of infestation soon widens to include plants not touched by the early migrants, a process carried much further by the winged forms than the wingless, the latter of course being restricted to plants within their easy walking diistance.

By the middle of September in Maine, and several weeks earlier farther south where the infestation gets an earlier start, the potato vines are as free from aphids as they were before the spring migration. To illustrate what has happened to the potato crop before the fall migration, however, the following quotation from the report of the State Entomologist of Connecticut for year 1917 might be cited.

"Apparently this infestation seriously checked the crop; the tubers were arrested in theiri development and a very small yield resulted. In a field at the Station farm at Mt, Carmel, the vines were large and vigorous and promised a good crop; but this field was heavily infested with aphids in July, and though sprayed and most of the aphids killed, the plants did not recover and died in a few days. The yield was very small, some portions of the field being hardly worth digging."

It is not an easy matter in most instances to ascertain how much of the injury concerned in an aphid infestation is due to the direct damage done by these countless minute insects each with its sharp beak plunged into the tissues of the plant and sucking sap incessantly for the duration of its life; and how much may be involved with early blight and other fungous diseases whose access to the plant is made easy by the innumerable wounds laid open by the greedy aphids. Both factors doubtless often function simultaneously, their co-operation working disaster to the potato crop.

It is always well to bear in mind concerning the injury inflicted by any plantlouse that so many elements of uncertainty enter into the career of these insects that it is quite impossible to predict whether such a pest is likely to trouble us for two or many consecutive years or succumb to some adverse condition and practically disappear for a long time.

The weather, for instance, plays an important part in the welfare of aphids, heavy rains washing the tender forms from the plants, cold days retarding the rate of their increase, while on the other hand, excessive heat hastening the development of the aphids as well as otherwise interfering with the normal growth of the plant.

Certain climatic conditions are favorable to fungous parasitism which may sweep out the plantlice from a large area in a few days' time. Then, too, in some seasons, predaceous and parasitic insects appear in numbers sufficient to render any artificial remedial measures superfluous.

Remedial Measures Discussed

A clear cut recommendation regarding remedial measures for the pink and green potato aphid is at present impossible to formulate so that it will apply definitely and equally to all localities and conditions of infestation.

If, as in the case with the "black stem rust of wheat," this insect proves to have but a single overwintering host plant there might be good reason for recommending an extermination of, or compulsory fall and spring spraying of, rose bushes in the vicinity of large industrial potato areas as the only means of control necessary to keep the pink and green aphid in check. But, though in Maine the rose is by all odds the favorite goal of the fall migrants and the plant upon which develop the sex forms of the aphid and which suplies the nesting site for the over-wintering egg from whch the stem mother hatches in the spring; it is by no means certaini that the rose is an absolute necessity to the life cycle of this insect in all localities. There is no doubt, however, that the potato grower who encourages a roadside growth of unsprayed wild roses in the vicinity of his fields and neglects to apply an aphid spray spring and fall to his cultivated roses is thereby providing the most suitable propagating site for an insect whose reputation for damage may be summed up in its Ohio nicknome of "Kaiser bug."

Records of successful spraying campaigns have been published from Ohio and Connecticut.

The final recommendations from the former state (Ohio Agricultural Experiment Station Bul. 317) are as follows:

"Based upon our observations and findings, confirmed by the general results of the field demonstration spraying campaign just referred to we believe:

"Nicotine sulphate 1½ to 2 teaspoonfuls to a gallon of water, or about 1 to 500, with enough soap added to form a suds, is the most satisfactory spraying material for the control of this species.

"Two applications or more may be necessary to control the scourge, and these applications under conditions such as prevailed this season should not be more than 3 days apart.

"Thoroughness of application is essential to success. Many failures to control are due to insufficient or improper spraying.

"Because of the wide range of hosts, clean culture is an important adjunct to other control measures.

"Spraying in the early stages of an outbreak is essential to successful control.

With proper equipiment, proper materials and thorough work, the pink and green potato aphid may be effectively and economically controlled."

During the outbreak in 1917 in Connecticut the demand for nicotine solution was so great that most retail dealers sold out their stock, and could not obtain more from the factory until too late to save the crops.

In consequence (to quote from the account by W. E. Britton and M. P. Zappe in the Journal of Economic Entomology, Vol. 12, p. 71. 72.)

"We decided to spray with kerosene emulsion to kill aphids only and demonstrate to the growers that they were not wholly dependent on nicotine solution. A common formula for

Prematuring and Wilting of Potatoes

Puzzling Trouble in Connecticut Discussed---Comparitively Little Known—Suggestions Given

There appeared suddenly in southern Conecticut an unusual trouble popularly designated as a blight, which was first called to the writer's attention on July 6th last year in a field that had grown potatoes for three years. In this field a spot had yellowed up and was dying prematurely and the owner said he had first noticed the trouble two or three days previous. Since then the writer has seen many fields and received numerous complaints of the same or similar troubles confined chiefly to the southern half of the state. Many fields have been visted and a careful examination made of the plants in the field and in the laboratory. The trouble seems to be a complicated one with indications that more than one factor may be concerned with it. However, the general conclusion that we have come to, to date, is that primarily, at least in most cases, the trouble is not due to fungi but rather to lack of sufficient food and moisture for continued plant growth. The fields visited have shown two or three types of the trouble, as follows:

1. A prematuring of the vines in which the stem and leaves gradually turn yellow, the plant often remaining erect, the leaves dropping off or dying, and finally the whole plant succumbing.

2. Plants wilting and flopping over as if the stem had not enough strength to support them. Parts normally green and no particular spotting on the stem.

3. A bronzing more or less of the stem and spotting; plants lopping over somewhat; frequently the stem is rather soft near the ground so that it is easily pinched together and giving somewhat the appearanec as if some fungus or borer had been at work.

We have carefully examined the stems above and below the ground in the field and cut many sections of the stem and leaves in the laboratory, and while we occasionally find bacteria and fungus threads which might aid in wilting, and a Phoma that might cause rotting, we have found as yet no definite association of these particular agencies with these troubles.

Professor Whetzel of Cornell who has made some study of the trouble in Long Island, seems to have come to the conclusion that the trouble there may be caused by a form of Phoma fungus disease which he claims to be new to this country. His investigations are not complete and we are inclined to believe that this fungus, if associated with the trouble, is not the responsible agent in the majority of cases in this state, although we have found such a fungus on some of the stems.

Our investigations lead us to the conclusion that the trouble cannot be associated with any particular type of seed, whether home or northern grown, or the character of the seed, whether first class or poor, or the conditions under which it was stored as to freezing, aeration, etc., although there are other troubles that may be connected with such unfavorable conditions. Neither does the trouble seem to have been associated in any way with care or lack of care, regarding spraying for either insects or fungi, since some of the fields thoroughly sprayed for both have gone down just as badly as those receiving no treatment whatever. We have found, however, that there are certain conditions under which the trouble has appeared more or less injurious, as enumerated below.

Time of Planting and Maturing Factors

The trouble first showed on Irish Cobblers or other early varieties, later appearing on the late varieties. Of course Irish Cobblers and Green Mountains are the varieties most frequently planted in this state and are the ones upon which the trouble has appeared most prominently. Dibble's Russet seems, so far, to have been the least injured variety, but is rarely grown. The time of planting or maturing of the plants seems to have had considerable to do with its appearance. In other words, the trouble does not seem to develop until the plants have bloomed and are in the stage where teh foliage has made its growth and most of the energies of the plant are bent to the formation of tubers. We have seen the trouble very prominent on Irish Cobblers when Green Mountains beside them did not show it, or on Irish Cobblers when near-by rows of the same variety planted a few days later did not show it. In time, however, both the Green Mountains and the later-planted Cobblers did show the trouble when they reached the same stage of maturity. We know of one farm where the owner planted Irish Cobblers and Green Mountains on four different dates covering a month, and the trouble appeared in the fields and varieties in the order of their planting and maturity, being quite severe on the earliest when just beginning to show on the latest, and the Irish Cobblers, showing sooner than the Green Mountains.

We have seen many cases where the trouble showed over a field when the vines under shade trees, especially apples, which are likely to be within the fields, were still quite green and unaffected. In many other cases we have seen where th efield was quite irregular that the vines were always green in the gullies on the lower portions where the earth was more moist and got the wash from the fertilization. Invariably in fields with gravelly knolls the trouble first appeared and showed more prominently in thees spots, no matter what the fertilization. In poor fields, insufficiently fertilized, and in leachy soils, the trouble has always been most pronounced especially if only artificial fertilizers were used. Fields that have been heavily manured, or had a complete fertilizer containing potash, have not suffered like fields where only a 4-10 fertilizer has been used. We have seen fields where a heavy coating of manure applied over part of it and a 3-10 fertilizer applied over all of it, having the vines on the manured part stand up in good shape while on the remainder it went down prematurely. In other fields we have seen where part of the land had been in crops the previous year and part had been newly plowed, with a 4-10 fertilizer used over all, having the vines make a better showing on the sod than on the remainder of the field.

We have also seen fields of poor or leachy soil on which a 4-10 fertilizer was used producing a fairly luxuriant growth under the favorable moist conditions of the spring and early summer, going down when this fertilizer had been used up or leached out, when it really needed plenty of fertilizer and moisture at the time of rapid tuber formation.

Possibly Lack of Plant Food

All these facts, together with the further one that a fungus should work most destructively in a rank vegetation where there is plenty of moisture, which is the condition in which the potatoes do not go down so readily, lead me to the conclusion that lack of moisture and sufficient plant food, of which potash is one of the factors, are primarily responsible for most of the troubles, rather than fungi, poor seed, or insects, especially lice, all of which have been attributed as the cause.

That plant food is a prominent factor is further impressed upon my mind by the fact that in the northern tobacco-growing sections, where manure and complete fertilizers, especially those containing a considerable amount of potash, have been used abundantly in past years, I am not able as yet to find this trouble prominent although in some sections the crops are beginning to suffer from lack of moisture. Furthermore, in school and war gardens where the soil in many cases is rather poor and only commercial fertilizers have been used, the trouble seems to be more prominent than elsewhere, as we might suspect.

I understand, besides Conencticut, this trouble has appeared in New Jersey, Long Island, Southern New York, and complaints are now coming in from Rhode Island and Massachusetts.

In 1916 in the Aroostock potato district of Maine, Irish Cobblers suffered with a trouble similar to that described under the third type. In this particular case many investigators, who were in that region at that time, attributed the troubel to lack of potash with possibly fungi as secondary factors. We had some slight yellowing of Irish Cobblers in Connecticut that year. In 1917 we had no complaints of exactly this type in Connecticut, although many fields did poorly which were said to have been injured by lice. Dr. Britton, our Entomologist, is now inclined to believe that not all the trouble attributed to lice was caused by them, although theer is no doubt that where they were especially abundant on the young vines serious injury resulted.

All these observations have led me to the conclusion that we must be careful in the future, so long as our fertilizers remain incomplete, in the character of the ground which we chose for potatoes, and in the manner in which we fertilize the same. If feasible, select sod land or land that has been well fertilized with the previous crop. Avoid worn-out or leachy soils. If possible fertilize with a heavy coating of well-rotted manure plowed in the previous fall or in the spring. This will supply humus, which retains moisture and nitrogen and potash, the most essential elements for potato growing. Where possible use a complete fertilizer. Where an incomplete one is used, do not place all of this on the land before planting potatoes, but use part of it once or twice after the vines are up. Practice rotation. Unless the soil is especially well adapted for growing potatoes never plant two years in succession in the same place. Use preferably northern-grown seed and of the best quality, and give the vines thorough cultivation and protection against insects and fungi. In other words, a potato vine, like a human being, responds to the best treatment and what it needs most are moisture, nitrogen and potash, with favorable conditions for obtaining these.

The fact that lack of moisture has had a very important bearing on this trouble is shown by recent injury to other plants, dying grass and trees losing their foliage, from the dry hot weather of July 21st to 30th. The potato is the most subject to drought injury of any of our cultivated crops, so naturally this is the first to show its ill effects. Ordinarily this is shown as tip-burn but this year the injury has not been so much of this type as in the prematuring of the foliage. Vines not too early or suddenly killed still put a considerable growth into the tubers, so the injury will not be so great in some fields as suspected. We have had no complaint of rotting tubers. Late blight is now here in some fields, but under dry conditions is doing no particular harm as yet. The abundant and general rain of July 30-31st put an end to the dry weather and should prove of great value to those potato fields not too far gone at that time.—By G. P. CLINTON, Botanist, Connecticut Agricultural Experiment Sation.

GRASS AND CLOVER ENSILAGE

(Experimental Farms Note)

When the term "ensilage" is used in Canada, it nearly always refers to ensilage made from corn, for the reason that corn is practically the only forage plant which is used for ensilage in this country. There are, however, a considerable number of forage plants which may be converted into ensilage of high feeding value but, so far, only such plants which cannot very well be cured into hay and which, at the same time, produce bulky crops have been utilized for the purpose. For the same reason, grasses and clovers are not looked upon as belonging to the class of forage plants from which ensilage may be satisfactorily and economically made, and yet the first ensilage produced in modern times was made from grass.

Thus, history tells us that the people living in the countries bordering on the south eastern coast of the Baltic Sea in Europe made it a practice long ago, to preserve their grass crops in an unique manner. Trenches were dug in the ground to a considerable depth and filled with freshly-mown grass. The grass was packed as hard as possible and, when the trenches were well filled, it was loaded down wit large stones so as to be kept under heavy pressure. After a certain time a product was obtained which to all intents and purposes was identical with what is now called ensilage. This method of converting the grass into a wholesome and nourishing food was later, in a somewhat modified way, applied to Indian corn in France where, as a matter of fact, the making of corn ensilage was first successfully attempted. From France the method was brought to this continent where it was perfected and soon gained universal popularity wherever corn could be raised remuneratively for fodder.

It is the irony of things that, while corn became increasingly popular as an ensilage crop, the fact that common grass was the first crop used for ensilage purposes was soon forgotten, so much so that at present only comparatively few farmers are awart that grass may be advantageously made into ensilage. And not only grass but clover and alfalfa as well, may be converted into excellent ensilage. Some experiments with grass, clover, and alfalfa ensilage fed to dairy cows which recently have been conducted at the Dominion Experimental Farm, Agassiz, B. C., strongly indicate that ensilage made from the latter forage crops constitutes a most valuable feed, the use of which spells profit to the dairy farmer. The practice of putting the grass and clover crop into the silo in about the same manner as for clover—ma therefore well be encouraged, especially if weather and labour conditions at harvesting time are not favourable to the making of cheap hay of the best quality.

M. O. Malte.
Dominion Agrostologist.

At the American Guernsey Cattle Club Sale held in New Jersey the other day a cow five years old sold for $12,500, a bull calf for $25,000, a yearling bull for $5,400, a mature bull for $5,500, and a heifer rising two years old, for $3.500.

Apple Orcharding in New Brunswick

By A. G. Turney, Prov. Horticulturist

The outlook for profitable apple-growing in this Province was never better and, indeed, so far as the opportunities are concerned, it is doubtful if it was ever as promising.

Profitable Apple-Growing An Established Fact

During the past few years the Department of Agriculture has done much to demonstrate that commercial apple-growing in New Brunswick is no longer something about which there is any doubt, but rather, that is is a fact—a natural resource of proved value and capable of large extension. The greater and more general realization of this fact has been accomplished by the holding of three large apple shows in St. John, second only in Eastern Canada in point of size and excellence to the Ontario Horticultural Exhibition, by the prominent displaying of our apples at the various agricultural exhibitions in the province, and also in Montreal, Toronto, Boston and London; and, lastly, by the conducting of demonstration orchards and the general educational work of the Fruit Division. These means of publicity of bringing the accomplishments of our fruit growers into very general realization will be continued and new ones, already, under consideration, will be put into effect.

Demonstration Orchards

The policy of conducting demonstration orchards will be continued in a modified improved and extended form. Some fine new large orchards which were planted about seven years ago as a direct result of the publicity campaign of this division, and which are now coming into bearing, will receive specal attention in the confident expectation that they will inspire the planting of many others. The teachings which they will undoubtedly yield and their relation to the present and future methods of apple-growing, selection and adaptability of varieties, etc., will be carefully and advantageously used.

Concentration on Certain Varieties

The work of the last few years has established clearly that our leading varieties of apples, those on which the extension of the industry is based, are Wealthy, Alexander, Fameuse and McIntosh (with McIntosh preferred to Fameuse) there are others that may be profitably grown in particular sections or localities but these four we can grow to perfection—so why ask for anything better? Given these varieties of proved worth and adaptability, the obvious thing to do is to exploit their production in the very best sense of the word—to demonstrate as widely as possible their superiority over other varieties for our conditions, and to ascertain the best and most economical methods of producing them.

To this end the efforts of the Fruit Division will be concentrated and new steps have already been initiated and much important work started. In 1918 the Division established nine new test orchards of Fameuse, McIntosh and Alexander and this year we will set out eight more new, but larger orchards of these varieties, including Wealthy, in various combinations and planting distances. These new commercial demonstration orchards, as they will be known, are being placed with leading growers so that the conditions of care and culture may be the best obtainable. Accurate and detailed records as to the cost of growing, etc., will be kept and published, and to a large extent these orchards will be pruned and their care supervised by the Fruit Division.

Provincial Nurseries

Previous to 1913 the demand for apple trees of the most suitable varieties for planting in New Brunswick could not be supplied entirely by the local grown stock, and hence the importations from Ontario, Nova Scotia and the United States. It is gratifying, therefore to report that, with the active encouragement and support of the Fruit Division, there has since been a comparatively large development of the nursery business, and the present supply of New Brunswick grown trees of the best varieties is fully equal to the demand, and consequently there is no need of sending out of the province for apple trees. The stock in these nurseries has been inspected for the past five years by officials of this division and found to be apparently free from the San Jose Scale, and generally in a thrifty and desirable condition.

The Fruit Growers Association

A strong and active Fruit Growers Association is essential to the progress of the industry and the Department has always given a large measure of practical support to it. Largely as a result of this support, the Association has been able to make a big increase in its membership, to foster and develop the spirit and practise of co-operation, to purchase for and supply its members with nursery stock, spraying materials and all kinds of fruit growers supplies and to engage in the co-operative marketing of their fruit. Under the fostering support of the Department, the Association has developed into an increasingly powerful factor for the extension of our apple industry and one that will always work in co-operation and with the support of the Department.

Pruning Assistance

Assistance in the pruning of orchards has been a feature of the work of the Division for some years, and alst year, realizing that shortage of help and other conditions might lead to more than ordinary neglect of orchards, the assistance in pruning was largely increased and many farmers availed themselves of this opportunity and thus kept their orchards in good condition. This policy, of providing competent men at a nominal charge of twenty cents per hour, to instruct and assist farmers in the proper pruning of their orchards, meets with unanimous approval, is of very considerable value in our present stage of development of apple-growing and is being continued.

Experimental & Educational Work in Spraying

Although orchard spraying is still capable of being much more generally adopted yet there has been a big improvement during the past five years, both in the methods used and thoroughness of the work done and the number of orchards being sprayed. Power outfits have been secured by most of the larger growers and the sale of barrel pumps for use in the smaller orchards has increased very rapidly.

In 1917, this Division, acting in cooperation with and under the direction of Mr. G. E. Sanders of the Domniion Entomological Laboratory, Annapolis, N. S., started a series of spraying experiments with the object of working out a thoroughly practical and efficient system especially adapted to New Brunswick conditions. Already, this work has been successful beyond out most hopeful expectations, so much so that we feel that the chief spraying problems of our orchards have been solved, in principle at least, although there may be room for minor improvements, and we are now able to recommend a system of sprays which we know from actual practice, may be relied upon to produce clean fruit even in an unfavorable season. It would be hard to over-estimate the importance of this work in its relation to the development of our apple industry and its combination and extension is am important part of the policy of this Department.

Co-operative Marketing

The greatest incentive to increased orchard plantings is the profitable marketing of our present apple production. Realizing this, the Division has paid special attention during the past two years to the co-operative grading, packing and marketing of what may be termed, the exportable part of the crop, and in this work it met with marked success, getting very profitable returns for the apples thus sold outside the province, raising the price on local markets and increasing the general demand for and reputation of New Brunswick apples. The continuance of this practical form of assistance is essential to a well rounded and mature policy of encouragement.

Summary

The conclusion of the war has not brought about any radical changes in the policies of the Fruit Division for the reason that those changes, together with the continuance of the former policies were decided on three years ago, in anticipation of the very situation which faces us today. Not only has New Brunswick maintained the pre-war conditions of her orchards throughout the four years of the struggle, but in point of organization and development, the Province is in a better position today than in 1914.

Farmers Success Depends Upon Retaining Soil Fertility

Soil is the source of all wealth. From the soil directly or indirectly human beings and all animal creatures obtain food. When the Creator planned this universe, he apparently provided every element necessary to sustain life and ordained that in the evolution of the world and the existence of man there should be no destruction of elements. These elements form numberless complex substances by uniting one with the other, and they perform them in accordance with fixed laws, and finally turns back in the form of gases, vapors and mineral salts to start anew their endless work of production.

While elements may be indestructible, they sometimes stray, some become lost and often many are misused. Were it not for such losses, nature's store of plant food would not be diminished. It devolves upon man, therefore, to co-operate with nature in order, first, to secure from the soil the full benefit of these elements, and secondly, to prevent depletion.

Most virgin soils contain a goodly amount of the essential morganic elements, as silica, phosphorus, potash, lime, magnesia, iron, sulphur, etc., while water and air contain inexhaustible supplies of the four great basic elements, nitrogen, oxygen, hydrogen and carbon. Standing between these two great groups of elements is the man called the farmer and upon him alone depends the ability to make available the actual and potential power in nature's store house.

If all of the elements and compounds which go to make up vegetable growth were returned to the soil and atmosphere, there could be no diminishing of fertility, but such is not the case. There is a difference between the amount taken from the soil and that returned, which may finally bring about absolute depletion in some of the elements, unless scientific methods are enforced by the tillers of the soil.

The farmer is therefore confronted with these two problems: First, to make available, plant food elements which exist in the atmosphere and in the soil, and, secondly to return to the soil, plant food and guard against wasting. The first problem involves several important operations, namely, proper drainage, good cultivation, sufficient water to grow the crop, and crop rotation.

The second problem (returning the fertility) is more or less interwoven with the methods of the first and the two can be summed up under the heading of GOOD FARMING. This requires careful management, although not difficult to perform and to actually increase the fertility of the soil over what it was originally is quite possible and frequently accomplished. To do this the farmer must rely upon live stock and returning the manure to the land with the least possible waste. He must raise clover or other legumes to transfer the nitrogen of the air to the soil and sell nothing but concentrated products, e. g., butter, milk, eggs, poultry, wool, pork, beef, mutton, vegetables, horses, etc., as against bulky products such as hay and grain. The former method returns nearly all the fertility to the soil; the latter nothing. THE FORMER IS FARMING, BUT THE LATTER IS MINING AND IT IS ONLY A QUESTION OF TIME TILL THE SOIL WILL BE DEPLETED OF ALL FERTILITY AND WILL NOT PRODUCE A SUFFICIENT CROP TO WARRANT CULTIVATING IT.

It is often profitable and sometimes advisable to apply forms of plant food other than those produced upon the farm. These may be used without disturbing the ordinary methods. The use of fertilizers calls for considerable care and it is just as easy to contract large losses from their misuse as it is to obtain large profits from their right use. The nature and composition of fertilizers is a subject well worthy of careful study. No farmer should use fertilizers unless he has proven by careful experiment upon his own farm, that they will return him sufficient profit. In short the following general practices will insure good profitable crops and the maintaining of the soil fertility.

1—Proper drainage.
2—Good plowing and cultivation.
3—Short rotation of crops.
4—Raising of live stock and feeding all roughages upon the farm.
5—Growing of clovers and legumes.
6—Returning the manure to the land with the least possible loss.
7—Using commercial fertilizers where they have proven profitable.
8—Careful management and elimination of waste.

$1,680 PAID FOR BERKSHIRE PIG

The British Berkshire Pure-bred Pig Society recently held their first annual show and sale at Reading, when 150 pigs were shown. A gilt was sold at $1,680.00, the highest figure recorded for the breed—this young pig won the championship of the show. A three-year-old sow brought $1,000.00 and another sow $1,180.

AUGUST 5, 1919

THE FALL FAIRS

The Maritime Circuit of Fall fairs will open at St. Stephen, N. B., on September 9th, when for the first time in its history, the Charlotte County Exhibition will be thrown open to exhibitors from all parts of the province, as well as to those of Washington County, Maine. The fair will continue for four days.

Woodstock Agricultural Society is also holding an exhibiton on the same days, and will throw its entries open to the Maritime Provinces and the State of Maine. A splendid exhibition plant is now in course of erection and is being rushed forward to completion.

The Fredericton Exhibition follows with the dates set for September 13th to 20th. Prospects are good for one of the best exhibitions ever held at Fredericton.

Next in order comes Chatham on September 22nd to 26th. This progressive fair association has opened its doors to all Canada.

The Charlottetown Exhibition will be held on September 23rd to 26th, and will as usual be a popular resort.

The Centreville Agricultural Society will also hold its exhibition during the week of Sept. 22nd.

The Yarmouth County Exhibition will be held on October 1st to 3rd inclusive.

Barnyard manure or commercail fertilizers help to make big yields.

SWATTING THE SCRUB SIRE

The details of a very practical plan for swatting the scrub sire have been worked out in actual operation in a Wisconsin county. An accurate survey of the county revealed the fact that 37 per cent. of the young bulls and 26 per cent. of the old bulls in service in the county were scrubs. As this was one of the good counties in one of the best dairy states in the Union, it is safe to assume that the percentage for the whole country would not run away under the figures given. An additional 37 per cent. of bulls, both old and young, were found to be grades, which left but 26 per cent. of the young bulls, and 37 per cent. of the old bulls pure bred. This survey, in addition to the foregoing data, gave the complete data for each township of the county, with the exact location and name of every man using a scrub or grade bull. Armed with this information, the three county breeder's associations, representing the Holstein, Guernsey and Jersey breeds, in co-operation with the farm bureau office, the state live stock breeders association, and other interested agencies, started a systematic campaign to replace every one of these grade and scrub sires with a pure bred. Accordingly every pure bred breeder in the county pledged himself to furnish a typical bull calf of pure breeding, from three to nine months of age, to be traded even up for one of the grade or scrub sires, which was of course to be sent to the block. The only string attached to this offer of an even exchange was that the pure bred calf be retained in service at least two years by its new owner. While in some cases this meant a little sacrifice on the part of the pure bred breeder in the matter of immediate returns for his calf —from the standpoint of the future it is fundamentally sound in its relation to the development of a community breeding center.

The full grown scrub would certainly bring more at the block than the young pure bred would command for veal, as many pure bred bull calves are disposed of; there would be no economic loss in converting these bulls into beef; the best of all the exchange effects at no cash outlay to the dairyman, a result that might require years of argument and demonstration to bring about—the swatting of the scrub sire, and the use of a pure bred in his place. We expect to hear of other counties getting organized to follow the lead of Fond due Lac County, Wisconsin. Why not take it up at the next meeting of your society?

PROFITEERS—WELL HARDLY

The city consumer has evidently made up his mind that the farmer is an out and out profiteer; the farmer from his side of the fence complains that he has been very much underpaid, even under war conditions. But neither side seem to have facts and figures to prove their case.

Last year, however, a farm survey was conducted in Oxford County by a representative of the Ontario Agricultural College, Ont. In this survey, which covered the returns from 450 representative farms for 1917, it was found that:—

> The average labor income, after allowing for such charges as interest on capital invested, depreciation, and the ordinary expenses, was $1,200 for the year. This represents the average net return the farmer secured for his own labor and that of his wife and smaller children. To secure it they worked 13 hours a day, seven days in the week for six months, and 11 hours a day for the other six. Making a nominal allowance for other than household work accomplished by the wife and small children, this figures out around 22 cents an hour for the farmer's laor, or considerably less than is paid for ordinary unskilled labor in the cities. These are average figures. They include the incomes of some of the best and most progressive farmers in Canada.

It would be well for city people who have been helping to raise the hue and cry of "robber profiteer" against their country brethren to give these figures a moment's consideration and compare them with remuneration they receive in their various professions and callings.

LOOKING AHEAD

"How shall I meet my responsibilities this year as a farmer and a citizen? How can I get the largest returns from my farm at a time when this is so much needed?"

These questions must be answered by every individual farmer. He must consider his own conditions, his own opportunities and his own responsibility. But there are some suggestions that will help those who are in a position to make the proper use of them.

It will not be wise nor expedient to retrench in productive expenditures. There will be an incentive to produce as much this year as the land will yield. The emergency times will require it. But the land must be no less capable of producing as much or more the following year. It would be unwise to use such intensive methods as will impoverish the soil for future crops. Who knows the future? Who can tell our needs a few years hence?

The use of improved implements and machinery should be used as extensively as possible. Each man and team must produce more than ever before. Tillage must be better; brain power must supplement muscle power; machine power must supplement animal power and man power to as large an extent as possible.

OUR RESOLUTION

Let us resolve this day to begin life anew. To start with a clean mind and a celan heart and a clean body. To do all things right and do right in all things. To love honesty, justice and liberty, to teach them and to practice them, but to despise injustice, dishonesty and tyranny. Let us help the weak and encourage the helpless, and divide our joys with the poor of the world, that they may know that we are not above them or beneath them, but with them and of them, and that all men are born equal, and all hold kinship with God.

Let us be cheerful and even tempered and not afraid to smile. Let us be ever thoughtful of others and unselfish in our desires.

Let us resolve to seek always the truth and fearlessly condemn the false; to so live that our daily lives shall be an open book, with nothing to fear, nothing to hide; to honor virtue, age and womanhood; to obey our laws; and above all things let us show our loyalty to our country, and faith in our God.—Ralph A. Sayler.

BEST SUBSTITUTES FOR HIRED HELP

Efficient farm machines are the best substitutes for scarce hired help. By using labor-saving implements, the Canadian farmer produces more per man than any other farmer in the world. Therefore, in the present crisis, he should use the most efficient machines and suitable farm power to make the necessary increase in production which war conditions demand. Old useless machines should be sold as junk and serviceable equipment, not needed, should be sold or made available to others. To lengthen the period of service, machines must receive proper care and lubrication when at work, and proper protection from the weather when not in use. Attention to these suggestions on the part of the farmer and machinery dealer will help to obtain the greatest efficiency from farm machinery and aid in the best distribution of new machines.

When a man is satisfied with conditions as he finds them, he might as well call in the undertaker, for the jig's up with him.

SHEEP ACTIVITIES IN NEW BRUNSWICK

Federal and Provincial Aid to the Farmer and Breeder

Mr. Norman Stansfield, Acting Chief Sheep and Goat Division, Ottawa, with Mr. J. H. King, Maritime Representative of the Livesock Branch have been in Fredericton this week conferring with the Hon. J. T. Tweeddale relative to the co-operation of the two departments for the further improvement of the sheep industry. Mr. Stanfield is very favorably impressed with the possibilities for sheep protection and likewise with the progressive legisatlion that has been enacted for the protection and purchase of sheep by the department. While in Fredericton Mr. Stansfield visited the wool warehouse and expressed himself as being well pleased with the quantity and quality of the wool accumulated.

Some very important decisions effecting both the farmer and the breeder were arrived at. The Federal department of Agriculture is offering a bonus of $5.00 a year for two years in succession to a farmer who will use a purebred ram. This bonus applies to farmers who have never used one before . The Honorable J. F. Tweeddale has given his assent to a provincial bonus of $5.00 for the same purpose, making a bonus of $15.00. It is anticipated that this bonus will be an incentive to the farmer for the purchase of more and better rams as it will make up the difference between the purchase price of a pura bred and a scrub. The motive is simply to demonstrate for two years the value of the pure bred sire as per the scrub, and if at the end of two years the farmer is convinced by concrete evidence, that is better lambs, then it is assumed that he will continue to use pure bred rams, but will receive no bonus.

Another decision affecting the owners of grade flocks was arrived at, viz., that if a group of twenty-five farmers in any district or parish will get together and appoint a representative to purchase stock the Department of Agrirulture will pay his travelling expenses to any place east of Fort William, Ontario, and will, if possible, have a representative go along and help make the selection. This idea should appeal to farmers' organizations throughout the country. The representative will have to purchase twenty-five rams in order to have his expenses paid by the government.

A scheme for the grading of pure bred rams by the breeders of New Brunswick was also decided upon. New Brunswick is the first country in the world to adopt this method, which is probably the most advanced measure yet taken by any department of Agriculture for the protection of the farmer who buys his stud sheep by mail. Briefly the scheme is as follows: Rams will be classed as Superior, Average and Common and will be marked 3 star, 2 star and 1 star respectively. The rams will be graded by an expert sheep man and if a farmer writes to a breeder for a 3 star ram, then he will be assured that he will get a first class article. Each ram will be marked. Further the Federal Government will bonus only 3 star and 2 star rams and will not bonus the Common or 1 star ram, consequently farmers desirous of taking advantage of the $15.00 bonus offered by the Provincial and Dominion Department of Agirculture should bear this in mind. The Provincial Department of Agriculture is granting a bonus of $3.00 and $2.00 respectiyely on each 3 star and 2 star ram produced by the breeders of the Province. 1 star or common rams will not be bonused in any way, and it is hoped that these 1 star rams will be finally eliminated from the trade.

T. G. HETHERINGTON,
Live Stock Supt.
N. B. Dept. of Agriculture.

THE SUPPLY OF RED CLOVER SEED IS EXHAUSTED

(Experimental Farms Note.)

Owing to the comparatively small quantities of red clover seed which were available for this year's seeding, there are many, especially among those who failed to give their orders until late in the season, who have been unable to secure any seed at all this spring. The seed merchants are practically all cleaned out, and the small quantities which are in the hands of individual farmers are negligible. As a matter of fact, there are only a few odd pounds left here and there.

Under the circumstances, it seems that it might be a good policy to go in for clover seed raising this season on a more extensive scale than usual, because the demand from the trade for clover seed for next year's seeding is apt to be large. Canadian-grown red clover seed has, moreover, especially in recent years, gained a high reputation for reliability and, as a result, it is in ever increasing demand. Everyone who has used Canadian-grown seed is satisfied that it is preferable to imported seed for the reason that it produces a crop which is more likely to escape winter-kililing and frost injury in general than a clover grown from imported seed. Canadian grown red cloved seed is therefore sure of finding a ready market in the Dominion.

The best red clover seed crops are generally obtained on clay land, particularly if it is sloping to the south or west. Thick stands which may lodge in case of a somewhat wet season do not favor the development of high yielding seed crops of good qualtiy and anyone contemplating raising of a red clover seed crop should, for this reason, set aside for the purpose such a field, or such part of a field, in which the stand is not too thick.

As the seed is harvested from the second crop, the first crop may be either pastured or cut for hay. If pastured, the cattle should be turned off not later than June 20th. In case pasturing is not found feasible or desirable, which is mostly the case when only a part of the field is being reserved for seed production, the first crop should be cut not later than the third week in June, or even earlier, depending on the condition of the crop. As a matter of fact, it is advisable to cut as soon as blossoms begin to appear generally. If cutting is delayed much longer, the chances are that the second crop, that is to say the seed producing crop, may be held back, whereby of course the seed crop may be prevented from maturing in good time.

In case weeds appear in the seed crop, considerable trouble in the cleaning will be caused and it is therefore of prime importance that any field set aside for seed production should be as free from weeds as possible.

Concerning the harvesting of the seed crop, we beg to refer to an article on the subject which will appear in the July issuse of the "Seasonable Hints."

WHY IS HOME GROWN CLOVER SEED THE BEST?

The Dominion Experimental Farms' system has for years advocated the use of Canadian-grown red clover seed on the ground that heavier and more reliable crops may be expected from the home grown seed than from seed imported from some other country.

The superiority of Canadian-grown red clover seed has been demonstrated over and over again, and, as a result, many progressive farmers prefer it to any imported seed and, knowing its superior value, raise the red clover seed themselves rather than take a chance of getting unsuitable seed through the trade.

In order clearly to understand why the home-grown seed is superior to the imported article, it should be remembered that there is not a single pound of red clover seed on the market which can be said to represent a distinct variety. In fact, every pound of red clover seed sold in Canada represents a mixture of a large number of varieties. What this means may be exemplified if we assume, for the sake of comparison, that all kinds of corn varieties are being mixed and the mixture thus obtained put on the market for seeding purposes. The comparison applies perfectly to red clover, for all red clover seed sold in Canada is a mixture of a large number of different types of plants. Some of these types are what is called winter-hardy, that is to say, capable of coming through the winters without injury on account of their hardp nature. Others, however, are tender types which, in this climate, are unable to stand the rigour of the winters.

As the ordinary red clover is a mix ture of hardy and tender types, there is always a certain amount of winter killing going on, the result of course being that the greater percentage of tender types in a clover field, the greater the winter-killing. On the other hand, the plants which come through the winter may be considered to represent a stock much hardier than the original mixture of hardy and tender types.

Here is where the value of home-grown red clover seed comes in for it is obvious that seed, harvested from a Canadian clover field from which a large percentage of the tender types have been eliminated through the weeding out process caused by the winter, is bound to produce a hardier and consequently more reliable and more remunerative crop than any imported seed which may consist of a mixture of both hardy and tender types. And, furthermore, it is obvious that the farther north the seed is grownfi the more suitable it is for a country like Canada, because the farther north it is grown, the hardier is the crop raised from it likely to be. In view of this we must strongly recommend, not only that red clover seed raising be taken up on a larger scale, but also that, whenever possible northern Canaadian red clover seed be used in preference to imported seed.

WHEN TO CUT GRASS AND CLOVER FOR HAY

It is regrettable that it is a too general practice among farmers in Canada to leave the hay crops to be cut much too long. There are, as a matter of fact, a large number of farmers who delay the cutting of the hay crop far beyond the time when it would pay them most to cut. In many cases the reason for the delay is that it is a general belief that a somewhat increased tonnage may be secured if cutting is postponed, and in other cases the late cutting is practised because it is even believed that a better quality of hay may be obtained than if the cutting were done earlier.

In the case of Eastern Canada, where mixed clover and timothy, or timothy alone, are the fundamental hay plants, a few suggestions based on experience may be found not to be out of order.

Tmiothy and red clover are the standard hay plants which universally are grown together. The clover is contributing the bulk of the hay crop the year after seeding, and the timothy is furnishing the bulk of the hay the following year or years. Supposing that a farmer has a field of mixed clover and timothy, what would be the best time for him to cut it for hay? The clover develops early and is ready to cut some time before the timothy has reached its best stage. Shall the farmer cut the hay when the red clover is in its prime, or shall he wait until the timothy is at its best, notwithstanding that the timothy mixed with it may not be as well developed as might be desired for the reason that the clover is the more vlauable part of the mixture. By cutting early, the clover is given a chance to recuperate and to produce a aremunerative second crop, which it might fail to do if the cutting for hay is delayed too long for the sake of the timothy.

In case timothy forms the principal part of the hay crop, which it generally does two years or more after seeding to hay, it is important to handle it for hay in a proper manner. Timothy, like most other grasses, has a period of its own when it has the greatest feeding value and when the hay made from it is apt to furnish the maximum feeding value per acre. This period is the time of blossoming. At that time, timothy is richest in flesh and milk producing constituents and, if cut for hay when in bloom, the best quality hay may consequently be realized. It is a mistake to believe that better crops may be secured if cutting is somewhat delayed. Some slight increase in the yield may be obtained but what is gained in quantity is lost in quality and feeding value pound for pound.

Under the circumstances, early cutting of timothy for hay must of necessity be recommended as the most economical method of securing a hay of the highest possibile value.

GASSING THE RAT

For the benfit of your readers who are pestered with rats about their farm buildings, I have enclosed a description of a method I adopted in getting rid of them that proved succesesful. There is not a better carrier of disease and vermin than the common rat, and I found out that they were the spreaders of hog cholera.

The rats had made a network of tunnels in the ground under the granary, the hog house and the feed yard. I blocked up all the entrances into the underground holes except the main entrance used most by the rats. Down this I put a rubber hose connected to the exhaust pipe of the car and filled the rat quarters with exhaust gas.

It is easy to tell whether there are any holes that have not been blocked up, because the gas can be seen escaping. After I made sure that the gas was not escaping into the out-of-doors, I entirely filled the rat tunnels with a heavy dense gas. I then pulled out the rubber hose, plugged up the hole and waited for results.

The first apearance of a rat in that part of the farmyard was about a month later. Again the rat quarters were gassed and this was done whenever any rats put in an appearance. Now a rat is an unseen thing in that part of my barnyard.—E. C.

CHEAP TANK FOR TREATING FENCE POSTS

A small but cheap treating tank for treating fence posts can be made from one of the galvanized steel barrels used for shipping oil and gasoline. These barrels, which can be bought for about $6 or $7, are 36 inches high by 22 inches in diameter, and by removing one of the heads with a cold chisel or otherwise, a tank 34 inches deep remains. This tank, which is heavy enough to serve the purpose of post treating, may be supported upon two iron cross-bars built into the sides of a brick or stonework fire place. Such a tank will hold about 10 or 12 posts of ordinary size at one time.

Perhaps the most convenient way of using such a small outfit without much attention is to fill it with posts and creosote either at night or in the morning and heat it to the required temperatue with a small fire. The posts may be left in until the end of 24 hours and another lot put in. In this way the posts are given an excellent opportunity to absorb creosote while but little time will ge taken from other work.

HORTICULTURE.

COMMERCIAL STRAWBERRY GROWING

Manning Ells, Port Williams, N. S., at N. S. Fruit Growers' Association

Strawberries seem to fit in well with orcharding. They can be grown in the young orchard until the trees have been out some fifteen to twenty years and there is no way in which a young orchard can be grown so cheaply as in conjunction with strawberries. With good cultivation the strawberry is practically a sure crop, and under all conditions of weather we have not had a failure in ten years, the crop not varying more than a thousand boxes to the acre one year with another. Some objection is raised that when growing berries one has to wait two years before any returns come in. This is true when starting a plantation, but where planting is carried on every spring you have a crop maturing every summer. Strawberries are the first crop to be harvested on the farm and bring in some money at a time when other sources of revenue are at a low ebb. Right here let me state that the man with an acre of berries to harvest this summer has a small bonanza in his hands.

Growing strawberries presents no greater difficulties and does not require any greater knowledge than is needed in any other hoed farm or garden crop. In starting a plantation select a piece of ground that has been under cultivation for at least three years. The June bug lays its eggs in old sod and pasture land and the white grub or young June bug is very fond of strawberry roots and will soon finish a new set plantation if there are any in the soil. It takes three years before they are all out of an old piece of sod. In this valley I think a loam or light loam is the most satisfactory kind of land for berries, it being the easiest to work and giving the highest returns because the berries will be earlier than in heavier land. We want to keep in mind that the early berry is the one that pays. By raising early berries the crop is out of the way before the haying season is on, quite an important consideration if we are to grow berries in a general way.

Preparing The Soil.

Prepare the land as for potatoes or corn. We like to get the stable manure on the fall or summer before and plow it in, plowing again in the spring as soon as the land is fit to work. In growing Dunlaps—and this is the only variety we would grow on a commercial plantation in the Annapolis Valley—it is not necessary to set them before the first of June to get maximum returns. If the Dunlap has one fault it is that it makes too many runners, too rank a growth when set early in the spring on very good land. Later in the season these runners pile over one another and take root so thickly that the producing plants are almost smothered out. For the same reason, strong nitrogenous fertilizers should be sparingly used on the Dunlaps when set early in the season. The best crops I have ever seen were grown on strong, well-manured land when the plants were set the last week in May.

On our own farm we begin to plant as soon as the land is ready and continue as opportunity offers right into June. We have a large plant business to take care of, however, and have to plant as soon as we get the time available. After planting it is most important that cultivation should take place at once. Plants that are cultivated within a week of planting will seem to come right along and get a much better start than those left until the weeds are showing above ground. If cultivation is started early and kept up once every week or ten days until the runners cover the ground, the heaviest part of the work is over. This constant cultivation gets the weed seeds all started to the surface and sprouted so when the fall rains come and the rows are nicely matted there will be few weeds left to come up through the young plants.

To get the best returns it pays to mulch the first year. Use marsh hay, headow hay, rushes or straw. The most of us will have to depend on oat straw and even at twelve dollars a ton we covered the whole of our ten acres with straw this winter. Many make the mistake of putting the mulch on too heavy. All that is required is enough to shade the plants; shake the loose straw along the rows as thinly as it can be spread, and from one to two tons of dry oat straw will mulch an acre. This mulch, when drawn between the rows as soon as the growth starts in the spring, will help to keep down weeds, will keep the berries clean and conserve moisture.

Up to picking time any ordinary farmer can grow several acres of plants with no more trouble than with the same acreage of turnips or potatoes, but the harvest is the limit.

PROPER CARE OF SPRAYING MACHINERY

The old saying that "More farm machinery is thrown away on account of neglect than is worn out," is especially true of spraying machinery. The records of most manufacturers will show that some spraying machines sold 10 to 20 years ago are still in use. This is due largely to the fact that these machines have been taken care of properly. Other machines are wrecks after two or three years' service, due entirely to neglect on the part of the men who have had charge of them.

The manufacturer of spraying machinery is constantly striving to make his output "fool proof;" but the stage has not yet been reached where a sprayer will operate successfully without oil, packing, or renewal of worn or broken parts!

A potato sprayer should do well two things: (1) Furnish pressure (at least 150 pounds) sufficient to spray all parts of the plant—the top and underside of the leaf, as well as the stalk. (2) Properly agitate the spray solution in the tank.

The sprayer should have a suction strainer of ample size (number 14 to 18 mesh wire) mechanically and automatically cleaned by brushes operated in conjunction with the agitator. It should have a filling strainer to fit the opening in the top of the tank through which all liquids are strained into the machine. More spray machines operate under low pressure due to clogged suction strainers than from any other cause. One great reason for this clogging is due to the spray solution not being thoroughly dissolved before it is put in the tank of the spraying machine. There are several good articles by the Agricultural Experiment Stations covering the proper mixing of spray solutions.

Getting the Machine Ready

Oil all parts of the machine (don't forget to oil the plungers both inside and out). Close valve to spray boom. Throw in clutch to pump. Close pet cocks on pump. Open safety valve. Start machine. When pressure gauge begins to register open valve to spray boom; close safety valve and adjust nut on safety valve to the right pressure. If necessary to stop in the field to make adjustments, close shut-off valve to spray boom; this will retain pressure in the pump air chamber or in the reserve tank so when the machine is ready to start it will not be necessary to back up for 15 to 20 feet in order to get up pressure. This is also a good plan to follow when turning at the ends of the rows.

Do not allow the machine to stand in the open when not in use. Draw off all liquids from the tank when putting the machine under cover.

When the packing becomes worn, and will not hold the liquid while the machine is operating under pressure, unscrew the iron packing cap, lift the brass follower out, remove the packing (which is in 4 or 5 separate rings) with a nail or any piece of metal bent in shape of a hook, put in four rings of new packing which comes cut to the right length, press down with the brass follower, screw on the packing cap, oil around each plunger, and start machine. Run for ten minutes. If packing does not hold liquid screw down packing cap slowly until the packing holds the liquid.

On the older types of pumps the brass piston or plunger is fastened to the iron cross head by means of a cap screw. If the cap screw works loose the inside of the piston or plunger will fill with the liquid. To tighten take off the connecting rod cap and pull the plunger out. Place in a vise (clamping the connecting rod), the bottom of the plunger up. Tighten the cap screw until it holds the plunger firmly. Place the plunger back in its place and put the connecting rod cap in position. Be sure that the liners are in the same place they were in when you removed the cap. Fasten the cap on the connecting rod with the two cap screws, making sure that all parts are fastened securely.

On the newer and better types of pump, the plunger or piston is made solid, making it practically impossible for the piston or plunger to work loose from the crosshead.

Putting the Machine Away

When spraying is finished for the day, clean all nozzles; fill tank one-third full of clean water (do not use dirty water) and operate the machine until this water is all sprayed out. Unloosen packing nut and oil outside plunger. This will give the packing a chance to expand, absorb oil and assure long life to the packing and plunger, and your machine will be ready for the next day's spraying.

At the end of the spraying season fill the tank one-third of clean water and wash the inside of the tank, pump, piping, hose and nozzles thoroughly. After you are sure that these parts are clean open the pet cocks and operate the pump until all liquid is discharged. This will asure you a good, sound pump for the next spraying season, and not a cracked one due to freezing of liquids left in the pump over winter.

Remove the plungers and empty all liquid from the inside of them and place in an inverted position inside of the tank. Remove the packing cap, the follower, packing and the chain. (Soak the packing and chain in any good lubricating oil.) Place all these articles, as well as the nozzles, inside the tank with the plungers; fasten down the cover securely and put the entire machine away under good shelter.

Make a note of all worn or broken parts and send your order to your dealer or the manufacturer of the necessary parts. Don't wait for next spraying season to do this. As soon as you receive these parts put them in their proper place on the machine.

Getting the Old Machine Ready

About four weeks before the next spraying season assemble the machine, fill 1-3 full of water and operate, without nozzles, until this water is discharged. You may find that the valves do not keep up the pressure. If this is true, unloosen the two nuts on the bolts that hold the air chamber and manifold in position; lift out the ball and seat, place the ball in opposite side of the seat and replace in proper position on the pump. Replace the gaskets with new ones if necessary. Put the air chamber and manifold in position and tighten the bolts. If any parts are missing, worn or broken, order them at once which will assure their reaching you before the bugs arrive.

Follow the foregoing and you may rest assured that the "sprayer" will be ready for business when it is wanted. —By William H. Gilbert, in Potato Magazine.

IMPROVEMENT OF THE GARDEN PEA BY SELECTION

(Experimental Farms Note)

Home Grown Seed is Generally the Best—It is now a well known fact that home grown seed is generally better that that in the trade. . Seedsmen themselves must feel that they cannot be sure of what they sell when they have practically no control over the production. It is certainly hard to understand why farmers do not produce on their own place more of the seeds which they require, especially those which are easily grown. Not only would they be surer of the vitality, but, which is very important in the case of vegetables, they would also be surer of the purity.

How to Improve Garden Peas—Garden peas are best grown on the flat in rows three feet apart. They very seldom cross, so that each plant is practically a pure line which can be isolated with comparatively little difficulty. Plants containing the largest number of long pods are chosen and peas from each plant are sown in separate rows. Of course, the more plants are chosen to start with, the greater the chance of finding one of extraordinary merit, but if fifty are used the first year, ten the third, and the best the fourth, it will be found that there will be quite an improvement over the initial stock.

What Was Done at Cap Rouge—At the Cap Rouge Experimental Station, the isolation of a good strain of Juno garden pea was started in 1912 when the yield was at the rate of twenty-six bushels of green pods per acre; in 1915, the yield had risen to forty-two bushels, and in 1918 to seventy-eight. Though the least desirable varieties were yearly weeded out, leaving only the best, still this strain was the highest producer of the eight tried in 1918.

What Farmers Can Do—Farmers need not go to the trouble of isolating good strains, as this work is done at Experimental Farms, but they can start with a good variety and put small stakes near a few plants which show decided superiority, as long as these have no advantage in regards to space, light, manure, or soil. The crop can be picked green, leaving only the chosen plants to mature peas, and the pods shelled by hand. This choice seed would be sown the next year, when the same work should be done over again, and so on each year, as the good results otbained are soon lost when selection is stopped.

THE SUMMER CARE OF VEGETABLES

(Experimental Farms Note)

Root crops, such as beet, carrot and parsnip, should be carefully weeded and thinned while the plants are still small. Parsnips should be thinned to about four inches apart; Swede turnips six to eight inches. Carrots may be thinned to one inch apart and, when large enough to use, alternate roots pulled, leaving the remainder about two inches apart. Garden beets may be similarly handled, but the final distance in this case should be about four inches. As beet tops make a very delicious early green vegetable, thinning should be done so that these tops may grow to a useable size. The soil should be kept cultivated and never allowed to bake or harden. This is particularly true with peas and beans if a tender, succulent crop is desired. Beans, however, should not be cultivated when moist with either rain or dew, as the plants, if injured under these conditions, are particularly subject to bean rust (the spores of this disease developing in the injured tissues).

Corn that has been sown in hills should be thinned to three or four plants to a hill, if the hills are two to two and a half feet apart. Cabbage and cauliflower plants require eighteen to twenty inches of space to each plant in the row, and the rows should be two and a half feet apart. The soil

Eureka
POTATO DIGGER

Saves Extra Help

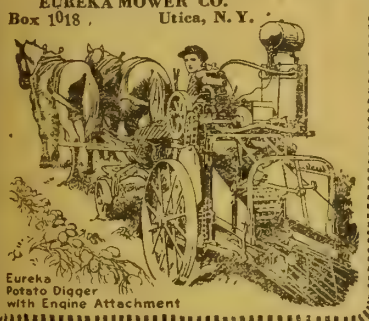
Pay for your Eureka Potato Digger with extra money earned by getting the whole crop early and selling while prices are high. Get the crop before it freezes in, without extra help.

The Eureka works in ground and conditions where other diggers fail. Because Eureka elevator and duplex shaker provide more separation; its big wheels and main gears give big power; its high clearance over shovels prevents weeds and vines bunching. Has vine-turner attachment. Special construction prevents frequent breakage. Growers report digging 150 and more acres without repairs.

Adapted for use with tractors; with or without engine attachment. 6 and 7 ft. sizes; several styles.

In stock near you. Write for catalog.

EUREKA MOWER CO.
Box 1018, Utica, N. Y.



Eureka Potato Digger with Engine Attachment

should be kept well hoed to conserve the moisture and encourage rapid growth. Where space is limited tomatoes may be grown in rows three feet apart and the plants eighteen inches apart in the rows and tied up to stakes. Corn, tomatoes, cucumbers, squash, pumpkins and melons all grow best on a light, warm soil. Five or six cucumber plants may be grown in a hill, the hills spaced about three feet apart; squash and pumpkin three or four plants in a hill and the hills six to eight feet apart. Where the soil is rich and warm and space limited, hills of cucumber, squash and pumpkin may be planted between alternate rows of corn.

Potatoes should be thoroughly cultivated to conserve all possible moisture; "ridging up" also supplies the tubers with loose soil in which to develop. However, in areas where there is a light summer rainfall, level cultivation will conserve the limited soil moisture more satisfactoryily. Spraying should not be delayed until there are signs of injury from the well-known potato beetle, or from one or more of the many potato diseases. Paris green and arsenate of lead have been found very satisfactory poisons for the beetle and can be applied at the rate of one ounce of Paris green to four gallons of water, adding an ounce of lime to neutralize any free arsenic present. Arsenate of lead adheres better to the foliage than Paris green and may be applied at the rate of one ounce to a gallon of water, if the paste form is used, or one ounce to two gallons if the powdered form is employed. Bordeaux mixture may be made up in small quantities in the following manner, employing wooden pails for mixing the spray. In each gallon of water dissolve two ounces of copper sulphate (bluestone) slake one pound and a half of quick lime (unslaked lime) in one gallon water, stir thoroughly and then add one pint of the lime water for each gallon containing the two ounces of dissolved bluestone.

SPRAYING MEETINGS

Mr. Geo. E. Sanders of the Dominion Entomological Laboratory, Annapolis Royal, N. S., has just completed a series of spraying meetings among the potato growers of Carleton and Victoria counties, New Brunswick. All the growers who availed themselves of the opportunity of hearing Mr. Sanders felt that they had been benefited. Farmers were invited to ask questions and relate their spraying experiences. Not a few, learned that they had not been mixing their Bordeaux properly and were put on the right track for efficient mixing. Others were using the most expensive poisons and not getting the most efficiency at the high price. Mr. Sanders enumerated the various poisons for sale in New Brunswick this year. He described the action of each poison. Not a few farmers reported burning of the leaves of their potatoes, and on explaining the poison used and how used Mr. Sanders was able to show them how they may guard against a repetition of the burning. He also showed the growers how they may make a considerable saving in purchasing their poison requirements.

He is at present experimenting with certain lines of poisons which according to all indications are going to prove a success and which will mean a saving of at least $50,000 per year to the Carleton county farmers. It will be well for all interested potato growers to keep in touch with Mr. Sanders and his work this year.

Fruit Packages

We Manufacture Strawberry Boxes and Crates for same, 6 qt. Baskets, Apple Boxes, Box Shooks, Apple Graders, Wheelbarrows. Now is the time to lay in a supply of Fruit Packages for the coming season. We have a good stock on hand, order early and ensure prompt shipment. Price on application to

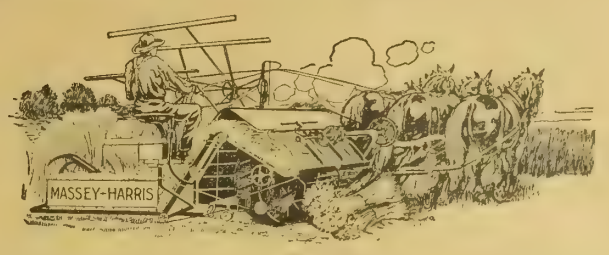
Hantsport Fruit Basket Co., Ltd.

HANTSPORT, N. S.

STRAWBERRY CROP

There are several important insects which do severe damage to strawberry plants and greatly reduce the crop every year. In Bulletin No. 92 "The Strawberry and Its Cultivation in Canada", prepared by W. T. Macoun, Dominion Horticulturist of the Dominion Experimental Farm, and obtainable from the Publications Branch, Department of Agriculture, Ottawa, information on these insects is given, along with methods for their control. Common strawberry diseases and remedial measures as well as general instructions for the gardener who is interested in growing this fruit are also included in this bulletin. Occasionally the yield of fruit is severely reduced by the strawberry weevil. This is a small dark snout beetle which cuts off the blossom buds. Early varieties of strawberries appear most subject to serious injury. In addition to clean cultivation protection may be obtained by coating the plants with a dust composed of one part (by weight) arsenate of lead and five parts finely ground sulphur.

Massey-Harris



The Binder that Never Fails

The Massey-Harris Binder takes all the worry out of Harvesting, for its owner knows that no matter in what shape the grain may be, his "MASSEY-HARRIS" will handle it and get it all. Years of actual work in the field have proven that for heavy crops, or down and tangled grain there's nothing to beat the Massey-Harris Binder. Thousands of farmers now look forward with happy and easy minds to harvest, in contrast to the old-time anxiety that accompanies uncertainty, because with a Massey-Harris Binder they take no chances—it gets all that grows.

Trussed and re-inforced at every supporting point, it is unsurpassed for strength and permanence.

The Reel can be set in seventy different positions, from sweeping the Guards to 31 in. above the Knife, all positions being obtained through one Lever which is within easy reach of the driver. An Adjustable Reel Brace prevents the Reel from sagging.

The Knotter, so simple, with nothing to get out of order, always ties a perfect knot and ties it tight, with the band in the centre of the grain.

Agencies Everywhere

Bordeaux mixture is the only reliable preventive for certain diseases of plants, and must be used despite the high price of copper sulphate.

Physical properties, such as adhesiveness, texture, spreading quality, and rate of settling are important factors in determining the efficiency of Bordeaux mixture.

The grower should regard spraying as an insurance and preventive and should always be prepared for an epidemic of the disease he expects to combat. If he wishes to secure good control, he should therefore use a preparation equivalent to the Standard Bordeaux mixture recommended for that purpose.

KEEP TOOLS SHARP

As a rule, persons who esteem their gardens lightly also keep a poor sort of tools. And we think that some of us who lay much stock by our gardens may also frequently be found wanting in this respect. We once saw a proverb to this effect: "If the iron be blunt, then must he put to it the more strength."

Keeping sharp tools means economy in strength. We never liked to work with old, dilapidated, dull tools. Somehow, there is a sort of enjoyment in working with a bright, sharp, well-set tool. To have the tools respond to our least effort gives us a greater respect for our work and naturally we pride ourselves more on what we accomplish. Looking about us we think that the farmer who takes no pride in what he does, never gets far. We find that after putting the hoes, spades, weeders, and other garden tools in good shape, we can keep them in good working order with a file for some time. An old knife has been found good to scrape the rusty places, and scouring will then be easy.

What is more discouraging to a boy or girl than a tool that is out of working order? It is difficult enough matter to interest many of our boys and girls in farm life at best, and then drowning out the little bit of interest they have taken by giving them poor tools, is a matter not to be considered lightly. By all means, give them good sharp tools and when they see what can be done they will take a sort of pride in their work, and the chances are they will stick.

PLANT LICE

Plant lice are green, pink or black in color and are so small they often escape notice until their numbers become so great they affect the appearance of the plant. Frequently, the presence of ants and the ants arebia presence of ants attracts attention and the ants are blamed with any injury that may result, but a close examination will reveal the sofe-bodied aphids or plant lice.

Spraying infested plants with nicotine sulphate to which has been added dissolved soap will kill plant lice. The nicotine sulphate can be purchased at drug stores and of dealers who handle spraying solutions. The commercial 40 per cent nicotine sulphate diluted with 800 parts of water, with two pounds of dissolved soap added to each 50 gallons, is a very effective spray, if it is applied properly. The plants must be sprayed thoroughly, being sure to get on the undersides of the leaves.

DAIRYING

FEEDING COWS ON PASTURE MEAL.—DOES IT PAY DAIRYMEN TO DO IT.

It is doubtful if any other farm subject has caused more discussion among dairymen in recent years than that of feeding concentrates to cows on pasture. It has always been a leading topic at cheese efactory and institute meetings and farmers' gatherings, where the opinions and expressions of dairymen have been freely expressed.

The contention of many good dairymen has been that it does not pay, others maintain, and with very good reason, that it can be profitably done provided the cows are given a rest from concentrates during the period of abundant pastures, usually during the month of June, while some argue that it does not pay to start feeding meal until the cool weather begins in October. The upshot of the whole controversy has been that neither the advocates for nor the objectors against have won many converts and the controversy still hangs in the balance.

However, after considerable study and investigation work carried on by agricultural authorities it is quite apparent that the answer must depend upon three factors. First and most important is the producing ability of the cows. If they are good producers they will return a profit, while the cows of low producing ability will not give sufficient returns to pay for the expensive concentrates they will consume. The second factor is the selling price of the milk and the third the cost of mill feeds. The former must be good, and the latter not too expensive.

As all good dairymen know the maximum milk flow under normal conditions is obtained during the months of luxuriant pastures, June and early July. During these months the ordinariy low-yielding cow produces her maximum yield of milk and it is doubtful if the feeding of expensive concentrates will make any material increase in her yield as long as the pastures are at their best and conditions ideal. But with the well-bred high-producing cow it is different. Her system has become concentrated upon milk-production to a very marked degree; the production of milk is her main object. The result is that such a cow cannot eat sufficient roughage or grass in a day to produce her maximum yield, consequently if she is to do her best, concentrated feeds must be given.

When pastures get short, the weather hot and flies bad, it is natural for cows to decrease in their milk yield, and any famer who has tried to keep a herd milking well by feeding meal has realized how difficult it has been, and the amount of meal required. But not so with the man who feeds meal steadily. His cows have been gradually building up and storing energy, and conseequently suffer less from the unfavorable conditions and do not decrease in milk yield, neither do they require so much meal to keep them milking heavily. Then later on towards fall when the weather gets changeable and often wet, the cows that have been fed steadily make a much better showing than those allowed to depend upon grass only. Furthermore, it has been found that cows given a fair allowance of meal throughout the summer months go into the stable in much better condition in the fall, go right along on winter rations and do not mind the change from green pastures to dry feed very much, consequently produce more milk during the winter months. Very often their lactation period is also longer.

On the other hand feeding cancentrates will effect a considerable saving in the meal bill. This roughage may consist of corn silage, soiling crops cut green, alfalfa, or one of the many other feeds available in midsummer. By following such a system the heavy feeding of expensive concentrates will not be found necessary, as experienced by the majority of successful dairymen.

The whole matter is simply a question of favorable local conditions and efficient management. If the cows are heavy producers, the milk sold for a remunerative figure, and meal can be obtained at reasonable prices, it will pay to feed concentrates the year around and more so if some green roughage is fed during the summer months. But, if the cows are low producers it is a very doubtful proposition and the only way to work it out is to try it for a year. At any rate the farmer will break even and he will then know whether or not to continue. It is a noticable fact, however, that the farmers who start feeding meal throughout the summer months continue the practice, which is about the strongest argument in its favor.

TEACHING THE BOYS AND GIRLS TO MILK

One of the most useful things a farm boy or girl can do is to learn the art of milking cows. Milking is easy or hard, according to the way it is done. Some learn more quickly than others. Some boys become better milkers than some girls while some girls make better milkers than some boys. Some persons it seems can never learn to milk well and rapidly. It may be because they do not like cows and do not want to learn. It may be by nature that hands, fingers and muscles are not adapted for this kind of work.

However, almost any farm boy or girl more than ten years of age can learn to milk cows right well. It is not a good thing for one to try to learn too young as a small person cannot hold a milk pail well enough and has not the strength to milk a cow rapidly and clean. It is never well for a child to try to milk a cow that will kick or has other bad habits. She should be left for older persons to milk.

It is a good thing for young folks to learn to milk cows and especially boys. The knowledge may become valuable some day when one goes out to make a living for himself. Good dairy help is in demand at good wages. If one learns to milk and knows how to handle dairy cows well when he grows up and should want work he will have no difficulty in finding a good job with dairy farmers. He can always make good money for better wages are usually paid the good dairy hand than to the common farm hand. A dairy education is one of the best educations a young person can acquire. One can learn a good share of this valuable knowledge right at home on his own farm by assiting in the milking and the care of the cows. It is a cheap but valuable schooling. One produces something while leanring.

Another good feature about farm boys and birls learning to mik is that the work can be done in a short time every morning and evening. It need not interfere with going to school or any of the other duties in the least. It will be a great help to the parents. What a young person learns about milking and milk will also be an aid in a better understanding of his or her regular school duties. This extra knowledge gained in the dairy will be a great aid to the young folks when they attend high school and especially when they attend college.

But how are we to go about milking? First we must learn the disposition of the cows and make them learn to like us or at least stand quietly while being milked. Kindness will win more from the cow than unkindness. Milkers must be quiet at their work. Dairy cows are quiet-dispositioned animals. They are disturbed and made nervous by loud talking and cruel treatment. Good dairymen and good milkers never strike their cows in any way no difference what the cow does. If she is bad, abusing her will make her worse. Talking to her gently and stroking her well will usually make her quiet and gentle. Some cows of course are easier handled than others but kindness and patience will win in the end with most of them.

One of the first things to learn in milking is to secure all the milk the cow will give at one time. One must learn to milk clean. Taking the last milk is called strippings. The strippings are the richest part of the milk, containing the most butter fat. If a small amount of milk is left in her udder she will give less milk at the next milking. If she is not milked clean for many days at a time she will drop in her yield and thus not be as profitable as she otherwise would be. Clean milking will help greatly in making her continue to give a large flow of milk. Rubbing and kneading the udder toward the close of milking will make the cow give a little more milk each time. This is important for a little more milk at each

PEERLESS PERFECTION
FOR CANADA'S BROAD ACRES
Put up a fence that will last a lifetime—a fence that can't sag or break down—that will hold a wild horse—that hogs can't nose through—that can't rust—a fence that stands rough usage by animals or weather and is guaranteed. PEERLESS PERFECTION Fencing is made of Heavy Open Hearth Steel Wire with all the impurities burned out and all the strength and toughness left in. Heavily galvanized. Every intersection is locked together with the Peerless Lock.
Stiff stay wires keep it rigid, making fewer posts necessary. Send for Catalog today. It's attractive, interesting, well worth the stamp. Best dealers throughout Canada handle our complete line.

SO EASY—

It takes the "EARNING" Out of the "CHURNING"

THE FAMOUS

RELIABLE CHURN

Hundreds of Farmers' wives have given up making butter because "churning was so laborious. Too much hard work for the money there was in it.

But they did not try the "Reliable" way. Churning isn't "play" with the "Reliable," but it is "easy work," a child of six can operate it. It gets quick results and is easy to keep clean.

The "Reliable" Churn operates with the efficient "Dash" motion, but with a high-geared rotary drive.

The "Reliable" is easy to keep clean, the double glazed, white stone jar lifts right out for washing.

milking will mean a big difference in a year's time.

Another important thing in keeping up a strong milk flow with cows is regularity of milking. Many cows dry up or stop giving as much milk as they otherwise would because they are milked at irregular periods for the day. Never omit milking a cow at her accustomed milking period if you wish her to continue to give much milk. But when you wish a cow to go dry or stop giving milk, skip one milking period for each day and do not draw quite all the milk from her udder. She will then go dry or stop giving milk within a short time without any udder trouble.

Clealinness is a very essential feature in milking. Be sure that your clothes, hands and pail are clean. One of the partly closed-top pails is the best kind to use. Before beginning to milk, wipe the flanks and udder of the cow with a damp cloth and then wipe them dry. This will prevent hair and particles of dirt from falling off the cow into the milk pail. The boy or girl who likes cows, likes to be around them and handle them will not find it difficult to learn to milk and will delight in doing the work.

THE DUAL PURPOSE COW

What are the requirements of a dual purpose cow? The question arises around the trend of things in regard to the supply of both milk and butter, and the resultant effect of the one detail of the cattle breeding industry on the other. In many discussions at farmers' gatherings, there seems to be a misunderstanding in regard to the term dual purpose. At least if there is not a misunderstanding there is a tendency for the argument to drift to comparing the dairy Shorthorn with the Holstein, Ayrshire or any of the other dairy breeds. There is plenty of room in Canada for the development of the cattle breeding industry, but there is no room for breed or class prejudices in the keen competition that will follow the financial needs of every country. In the immediate future there must be an equal pulling of the cattle breeding team, before the national prosperity wagon gets moving towards the export trade that must be catered to, both in beef and dairy products.

Dangers of Dual Purpose Breeding

The leading dual purpose breed is the Shorthorn, but though this particular breed is naturally adapted for this characteristic, there is existing danger in developing dual purpose cattle. Many who have started out to breed dual purpose Shorthorns are destined to make a failure in so far as adhering to the double purpose is concerned, unless they pay more attention to beef and a little less attention to milk. It is not impossible to breed a very high type of cattle that will produce a fair amount of milk, and still possess the conformation necessary for them to be included as very good specimens of beef animals.

The whole tendency on the part of some breeders seems to be towards milk, and they go into the game of producing dual purpose cattle, seeing nothing but heavy milk production. The danger to the breed or the dual type lies in the man who looks for conformation that denotes milk formation alone. He never looks much above the cow's underline; her udder, milk veins and wells are about all he examines, and a cow that fits him there is generally, slim-necked, narrow chested, sharp on the back; an all round mean individual from a beef point of view. The black and white Holstein has been developed to meet this single purpose of milk production by the highest attainment in breeding art, and there is no reason for Shorthorn breders seeking to raise a red and white Holstein. If the cattle bred and named dual purpose Shorthorns are to be real dual purpose animals, first attention must be paid to meat, and with it get as much milk as possible without seriously injuring the beef tendencies of the breed.

Laying Dual Purpose Foundation

In laying the foundation for a dual-purpose herd the buyer or breeder should be well satisfied with cows that give from 6,000 to 8,000 lbs. in each lactation period, provided these cows show good beef type and Shorthorn character. Pushing for high records is bound to be carried too far and will result in dairy Shorthorns, a class of animals which should not be eligible to be called dual-purpose. The name "dairy Shorthorn," is a misnomer because, under existing conditions, there is no excuse for such animal. We have our distinct dairy breeds which fill the bill for milk and cream as well as one could expect, and we have our distinct beef breeds which produce the acme of excellence for the block. The place for the dual-purpose animal, and it has a very large place in Canada's agriculture, is on the average farm, where the man is so situated that he can make more by a combination of a fair supply of milk and good beef calves than by straight beef or straight dairy operations. In order to breed and maintain a herd of the kind of cattle that will produce good steers it is necessary that attention be paid to meat, and that milk production be not overestimated or over-worked. A great many of the breeders who are enthusiastic over the dual-purpose cow are headed straight for a red and white dairy cow, which is a mistake.

Avoid the term "dairy" in speaking of any type of Shorthorn cattle, and stick closely to the requirements of a good all-round cow, namely, meat as well as milk. This will necessitate some attention to the size and general ebef qualities of the cows used in the herd. Select nothing but the big, roomy females which give evidence of being able to produce a good calf as well as a fair-sized pail of milk. Forget about the 15,000 and 20,000-lb. records, and lay more stress on the 15,000 or 1,800-lb. mature steer, or the 1,000-lb. baby beef at twelve to fourteen months of age. Dual-purpose means serving two purposes, not simply giving milk.

The quantity of milk that a cow gives does not always determine her value . Th ecost of production is a factor that must be considered. Some cows give twice the quantity of milk on the same amount of feed.

Thoroughly clean milking is important, not only as a means of developing the milking power of the cow, but also to produce richer milk.

To prevent bloating in cattle the herd should be shifted by easy stages from dry or scanty feed to abundant or luxuriantly growing fodder.

Efficiency

ALPHA Trade Mark

THE ALPHA Gas Engine is equally efficient in delivering the most power with the lowest fuel consumption, whether gasoline, kerosene or natural gas is used for fuel.

The ALPHA is also efficient because of its conservative power rating—each size has a generous reserve power above its rating, which permits of occasional overloads.

The De Laval Company is very efficient in rendering prompt service—well worth the consideration of any buyer of a gas engine.

If you don't know who handles the ALPHA in your vicinity, write nearest sales headquarters for his name.

COMMON DISEASES OF CATTLE

Troubles of the Respiratory System

The Cow in Health and Disease is the title of a new agricultural book just out of which the Burton Publishing Co. of Missouri are the publishers. Written by G. H. Conn, formerly veterinary inspector for the Bureau of Animal Husbandry of the U. S. Dept. of Agriculture, it embraces the fundamental principles of hygiene, the proper care and treatment in all common diseases.

It is a good practical book for dairyman. From it the Ottawa Farm Journal takes the following:

Cold in the Head

Cold in the head, also known as catarrh of the head or sometimes rhinitis, is most often brought about by animals that are accustomed to shelter being exposed to damp or stormy weather. This condition is usually mild and very seldom fatal, but if complicated by a severe sore throat it is sometimes fatal. It may also be caused from irritating or noxious gases. At first a reddening of the lining of the nostrils and eyes is noticed. This is quickly followed by a watery discharge from the eyes and nose. At first not much attention is paid to this condition but the discharge becomes more profuse and the animal develops a high temperature and the discharge may become heavy and contain pus. The animal becomes greatly weakened and is dull, does not move around much, has an impaired appetite.

The first thing that should be done is to get the animal into a warm yet well ventilated barn. If cold, blanket the animal. All drinking water should have the chill removed. Only the best of feed and that in small quantities should be given. Take six ounces of spirits of camphor and two ounces of fluid extract of belladonna and give one (1) tablespoonful of this mixture in a little water as a drench about every three or four hours. Good care is the most essential thing in the treatment.

Bleeding from the Nose

This condition is often spoken of as epistaxis, and is quite rare in cattle. It may be the result of injuries the same as in other animals, but it is not at all common. In aged cows in an unthrifty condition we have sometimes seen quite a severe hemorrhage or bleeding from either one or both nostrils. This usually takes place from a month to six weeks before the pregnant cow gives birth to her young. Does not occur in cows that are not with calf. The bleeding may persist until several pints of blood has been lost and then cease of its own accord, but many times leaves the animal in a weakened condition. If this condition is not properly treated these hemorrhages may recur at intervals of a week or ten days and then at calving time if the cow experiences any great difficulty in giving birth to her young it may leave her in such a physical condition that death will result.

Keep the animal quiet and bathe the head and nostrils with cold water. Apply cold water to the head. Tie the head up to a rack or beam. If it does not stop within a reasonable time call a veterinarian who can either use stypic injections to check it or hypodermics of adrenalin. To prevent the recurrence of the hemorrhages take eight ounces of the tincture of iron chloride and of this give two (2) tablespoonfuls in water as a drench, night and morning until the cow has calved when all danger will have passed.

Bronchitis

This is an inflammation of the mucous membrane lining the main bronchial tubes, be they the main bronchi or the capillary bronchial tubes. This condition is most often spoken of as catching cold. It in itself is not often fatal, but if complicated with other diseases it may prove fatal.

The animal's temperature may go up to 104 or 105 degrees. A cough is present which may be and usually is indistinct and incomplete. The inspirations are incomplete and short and gives the animal much pain. The expirations are prolonged. By placing the ear over the lungs various sounds may be heard corresponding to the extent to which the disease has progressed and the amount of exudate that is present. If, however, these bronchial tubes fill up with fluid the animal dies from suffocation. The appetite is lost and the pulse is fast and hard.

The animal should be placed in a well ventilated and comfortable box stall. The bowels should be kept in good condition by the use of laxatives and proper feeds. Keep the cow warm even though it requires blanketing. Use the following: Fluid extract belladonna, 2 ounces; spirits of camphor, 4 ounces, and aromatic spirits of ammonia, 10 ounces.. Give two (2) tablesoopnsful in water as a drench three times each day. The animal should be fed lightly and it should be of the best quality. This condition is apt to become chronic and then not a great deal can be done for it in many cases. If the case seems severe from the start a competent veterinarian should be employed.

Pleurisy

This is an inflammation of the membrane lining the chest cavity and that covering the lungs. It is rarely found as an independent disease, but usually found associated with pneumonia and is no doubt cased by the same disease germ. It may occur as an independent disease due to a fractured rib or a deep punctured wound.

When the animal is first noticed it has a great deal of pain. It does not move around much and when it does it will move as though foundered. The breathing is very fast, but is mostly abdominal and very shallow. The ribs are fixed. Movements of the animal causes the animal to evince pain. A short grunting sound is heard most times in breathing, and the expiration is much longer than the inspiration. The muzzle is hot and dry and the appetite is absent. The animal is constipated and the temperature will be around 105 or 106 degrees Fahrenheit. If the ear is placed over the chest cavity a hoarse rasping sound is heard, and this is caused by the rubbing together of the two inflamed surfaces. After a couple of days the temperature drops to 103 or 104 degrees and the animal begins to eat and secretions of the serous membranes begin to fill up the chest cavity and the sounds become less harsh as the cavity fills up. If medicinal treatment can not stimulate the absorption of this fluid in the cavity, the animal gradually grows weaker, the breathing shorter and more hurried and the animal has an anxious haggard expression, which is soon ended by death. If a veterinarian can be had that can perform an operation and draw off this fluid from the chest cavity from time to time it may be the means of saving the animal's life. Death will not usually occur sooner than from ten days to two weeks, nor later than the third week.

Give the animal the same general care as recommended for bronchitis. Keep the bowels active. Give the same treatment for the cough here as mentioned under bronchitis. Take of fluid extract of byrony and one (1) tablespoonful in a little water every three hours; this will very materially assist in the absorption of the exudate. Take of oil of mustard one half ounce and petroleum eight ounces. Thoroughly mixed, rub in on each side of the chest over the lungs. Do not rub too vigorously; this will have the same effect as a mustard plaster and is much easier kept in place. If the life of the animal is threatened it requires an operation as mentioned above which must be performed by your veterinarian.

Pneumonia.

This condition is divided by most authors in at least three different types or classed in three different groups, but we feel that very few individuals can differentiate between these conditions clinically, and as the treatment of them all is practically the same, we will speak of it simply as pneumonia. All of these types are caused by the same germs and the only difference is in the way the respiratory organs are affected.

The condition immediately preceding the pneumonia of cows is congestion of the lungs. The animal may be seen having a chill which may last only two or three hours or which in other cases may last several hours. This may be of short duration and escape the attention of the attendant. The temperature will be found to be 105 or 106 degrees Fahrenheit, and occasionally even higher than that. The respirations are greatly accelerated and very shallow, the pulse is quick and hard and the nostrils are dilated; a cough may be present at this time. The nose is hot and dry and the animal is usually constipated. Pressure between the ribs over the lungs gives the animal pain. The animal stands with the forelegs spread apart and the elbows turned outward. The hair is standing on end and the skin is harsh and dry. On placing your ear over the region of the lungs a soft crackling, snapping sound will be heard. During this time the animal stands most of the time. After this first stage has passed the temperature drops somewhat and the animal lies down most of the time. The expression becomes haggard and the pulse becomes hard and wiry. The secretion of milk is almost suspended. The sounds of the lungs are nothing but a whistling or wheezing sound. If the lungs could be seen at this time they would very much resemble the liver in appearance.

If the animal is going to recover the cough becomes loose, and the other symptoms begin to subside, the appetite returns and the animal is generally improved in all ways. If, however, the case is not progressing favorably the breath will have a foetid smell and is taken in very short gasps. The extremities are cold and feel clammy and the pulse can not be felt. These symptoms are an indication that death is a matter of a very short time.

It is doubtful after the first symptoms of pneumonia have developed if it is possible to abort the disease, but we do feel that if intelligently handled at this time that the severity of the attack can be so lessened as to make it a comparatively slight ailment in many cases and greatly lessen its effects in most others. This condition should be treated early, as this is the time when the real good is done. In this condition the more fresh air the better, just so there are no draughts. Blanket the animal well and then see that there is an abundance of fresh air. See that the bedding is clean and plenty of it. The chill should be taken off the drinking water. The feed should be given often and in small quantities and should be appetizing. The first thing to do after blanketing the animal and making it comfortable in the right surroundings, is to apply a coating of the mustard and petroleum as referred to above. Have your druggist put you up several powders of Sparteine sulphate, each containing 30 grains, and dissolve one of these in a small quantity of water and give every four hours. If the animal can be kept eating it will greatly favor the patient's chance for recovery. For this take fluid extract of nux vomica and gentian of each two ounces and give of this one-half tablespoonful every three hours in a little water. If the animal is constipated give a small laxative dose of Epsom salts or oil.

Heaves

This condition is also known as emphysema and is caused by a rupture of the very small air capities of the lung. It makes a peculiar respiratory action in which the inspiration is normal, but the expiration is prolonged and dfficultiy n expeliling the air from the lungs. The diagnosis can be

Bright Prospects

It looks as though the demand for beef will be strong for some years to come, and the man who is in line for greatest profits is the Shorthorn Breeder.

We haven't room to give our reasons here, but write the Secretary for our free publications, which furnish facts.

made from this characteristic breathing. The animal is usually emaciated, hide-bound, and the coat is staring.

There is no treatment for this condition and as it does not materially affect the milk flow nor the appetite and the best thing to advise is to prepare such animals for the block, where their condition is such that they will make good meat, and why not destroy them for humanity's sake?

SHEEP ACTIVITIES IN NEW BRUNSWICK

Federal and Provincial Aid to the Farmer and Breeder

Mr. Norman Stansfield, Acting Chief Sheep and Goat Division, Ottawa, with Mr. J. M. King, Maritime Representative of the Livestock Branch, have been in Fredericton this week conferring with the Honorable J. F. Tweeddale relative to the co-operation of the two departments for the further advancement of the sheep industry. Mr. Stansfield is very favorably impressed with the possibilities for sheep protection and likewise with the progressive legislation that has been enacted for the protection and purchase of sheep by the department. While in Fredericton Mr. Stansfield visited the wool warehouse and expressed himself as being well pleased with the quantity and quality of the wool accumulated.

Some very important decisions effecting both the farmer and the breeder were arrived at. The Federal department of Agriculture is offering a bonus of $5.00 a year for two years in succession to a farmer who will use a pure bred ram. This bonus applies to farmers who have never used one before. The Honorable J. F. Tweeddale has given his assent to a provincial bonus of $5.00 for the same purpose making a bonus of $15.00. It is anticipated that this bonus will be an incentive to the farmer for the purchase of more and better rams as it will make up the difference between the purchase price of a pure-bred and a scrub. The motive is simply to demonstrate for two years the value of the pure bred sire versus the scrub, and if at the end of two years the farmer is convinced by concrete evidence, that is better lambs, then it is assumed that he will continue to use pure-bred rams, but will receive no further bonus.

Another decision affecting the owners of grade flocks was arrived at, viz. that if a group of twenty-five farmers in any district or parish will get together and appoint a representative to purchase stock, the Department of Agriculture will pay his travelling expenses to any place east of Fort William, Antario, and will, if possible, have a representative go along and help make the selection. This idea should appeal to farmers' organizations throughout the country. The representative will have to purchase twenty-five rams in order to have his expenses paid by the government.

A scheme for the grading of pure bred rams bred by the breeders of New Brunswick was also decided upon. New Brunswick is the first country in the world to adopt this method which is probably the most advanced measure yet taken by any Department of Agriculture for the protection of the farmer who buys his stud sheep by mail. Briefly the scheme is as follows: Rams will be classed as Superior, Average and Common, and will be marked 3 star, 2 star and 1 star respectively. The rams will be graded by an expert sheep man and if a farmer writes to a breeder for a 3 star ram then he will be assured that he will get a first class article. Each ram will be marked. Further, the Federal Government will bonus only 3 star and 2 star rams, and will not bonus the common or 1 star ram. Consequently, farmers desirous of taking advantage of the $15.00 bonus offered by the Provincial and Dominion Department of Agriculture should bear this in mind. The Provincial Department of Agriculture is granting a bonus of $3.00 and $2.00 respectively on each 3 star and 2 star ram produced by the breeders of the Province. 1 star or common rams will not be bonused in any way, and it is hoped that these 1 star rams will be finally eliminated from the trade.

SENSATION IN AYRSHIRE CIRCLES

The shipment of 91 head of registered Ayrshires from Quebec to California has caused quite a stir among Ayrshire enthusiasts. This is the biggest deal in Ayrshire stock that has ever gone through in Canada and represents a cost of over $25,000. These were purchased by E. B. MacFarland for his ranch "Steybrae" at San Mateo, and the "Penobscott" ranch in California. Mr. MacFarland and his Farm Manager Jack Glass personally made the selections, ably assisted by Gilbert McMillan, Huntingdon, Que., who looked after the assembling and shipment of the stock. This shipment left Huntingdon on July 7th, via express and made a most imposing spectacle as they were a beautifully uniform lot of good sized commercial cows, true to Aryshire type, and will doubtless do much to increase the popularity of the Ayrshire on the Pacific Coast.

The largest purchase from any individual breeder was the buying of the entire herd of James Davidson "Ayrmont" Waterloo, Que., with the exception of the stock bull. This comprised 71 head,—40 cows, 15 heifers and 16 calves. The cows were a fine lot of good big cows, 30 of which were daughters of Vaudreuil Pride 3rd., a son of Auchenbrain Pride (Imp) a bull carrying the best breeding obtainable in Scotland. Possibly the most outstaing feature of the purchase was the bunch of 16 calves sired by Auchenbrain Timekeeper (Imp), which were undoubtedly one of the strongest groups of calves by one sire ever seen together. There is no question but that they could have held their own in the calf classes in any of the Canadian or American show rings.

Other purchases included the beautiful cow "Sunnyside Governess" from J. W. Logan, Howick. She being one of the top-notchers of the purchase. From Gilbert McMillan "Maple Leaf Lily", probably the "cream" of the shipment,—also a granddaughter of Bargenoch Gay Cavalier, and a grand daughter of the grand old cow Auchenbrain Hattie 6th., (Imp). Two very fine dairy cows were got from D. MacFarlan, Howick. From J. B. Black, Lachute, came a beautiful pair of 4 year olds, "Willowhaugh Spicy Jean" and "Willowhaugh Dolly Grey" winners at 2 and 3 year olds at local fairs and 1st, and 3rd, at Ottawa as three year olds in 1918. Two sweet heifers "Auchenbay Jean" (Imp), and "Burnside Miss Courtney" 2nd prize junior yearling at Ormstown 1919, from R. R. Ness, Howick; a beautiful heifer "Lulu" from Erskine McOuat, Brownsburg, also one from Wm. Rodger, Lachute and two nice ones from Stanley J. Hamilton, St. Eustache; one from Hector Gordon, Howick, and two fine 3 year olds each from David Pringle & Sons, and Rennie Bros., Huntingdon, and Wm. Gruer, Riverfield.

THE FANNING MILL

To keep the fanning mill stationery: Get two pieces of three-eighths-inch iron, 6 in. long, sharpen one end of each, tapering gradually and triangular, four staples to fit irons. Drive two staples in the corner post near the bottom, I inch from the bottom and 2 inches apart, do the same in the opposite diagonal post. Now drop the iron pins down through the staples and drive in the floor just enough to hold tight. When moving the fanning mill lift up oc the pins and the pins can be easily taken out by tapping with a hammer.

THE HORSE

CAN THE TRACTOR BE DEVELOPED TO BECOME THE RIVAL AND DO AWAY WITH THE HORSE

The rapidity with which the gas tractor is being introduced is one of the most remarkable developments in the machinery line for past years. The tractor undoubtedly finds the greatest field upon the farm, and where ie becomes the natural rival of the horse. I think it is well for us to note a few points of comparison in order to see whether the tractor has been made to surpass and excel the horse, where to equal it, and wherein improvements must be made in order to offer the animal serious competition at the present time.

Naturally the horse is even to day our best all-around source of work power for farm purposes, notwithstanding the fact that the tractor is being placed on a number of farms yearly, and many farms need a good tractor for the various duties to be performed.

The crop of horses this year will probably be worth on the farm five or six times the value of our entire output of gas tractors for domestic purposes. We may now compare the gas tractor and the horse on many points worthy of consideration without presuming to have covered the subject.

We could take up, for instanace, the question of thermal and commercial efficiency, flexibilitiy, attendance and shelter required, the relation of power to weight, endurance, size of opwer units, safety, and many numerous other factors, and still the list would not be exhausted, as this subject is a difficult one, and many complications enter into its makeup.

No doubt endurance is the horse's weakest point. Ten hours a day is often assumed as a horse's working period. Many authorities on the subject claim that eight hours is better for the health of the animal and some say that six hours under a heavier load will accomplish the same amount of work with less wear and tear on the horse. The average farm horse can not be depended upon for more than 15 to 16 hours of pull a day, nor more than six hours of work per day, as an average of even the busiest months of the year. A gas tractor will net 17 to 18 miles of furrow travel in ten hours and can double this in 24 hours.

Now properly handled, working about six hours a day, well and carefully fed, a horse may have a working life of ten years of about 1,000 hours each. The average farm horse will do exceedingly well to develop 500 horsepower hours per yeear, or 5,000 in a period covering ten years. A tractor carefully looked after will probably double this for each rated horsepower. This is especially true in threshing as the tractor develops about twice as much as in pulling, while a horse furnishes probably 15 to 30 per cent. less, owing to inefficiency of the apparatus through which his power is transmitted.

The horse cannot be overhauled when he wears out or when he runs down and stops. He must be kept in good working conditiion by constant attention and precaution. In this respect he is probably superior to the tractor as he demands more attention and care from the owner and from the operator; however, he needs the same care the year around, which is somehwat of a mystery, especially when the owner has nothing to do but to watch the horses eat.

Yet the horse has manay advantages over the tractor. We could consider weight, that is undue pressure upon the ground. This is constantly urged as the objectionable feature of the tractor. A horse while pulling upon the ground effects an average pressure of 25 to 30 pounds per square inch and a mule even more than this. Figuring roughly, about one-fifth of a horse's ewight may be taken as his maximum sustained draft, and six to eight miles an hour his maximum sustained speed for anything more than a nhour or so per day. The draft horse ordinarily gives the largest volume of work per day. Either his speed or load can be increased at the expense of the other until all of the horse's energy will be taken in moving himself at no load, or he will be loaded down until he can not move at any speeed whatever. Within these limits the horse has a large range of flexibility, which so far, has not been aproached by any tractor engine made. A horse for an instant only has been known to exert a draft of 1,800 pounds for 1,600 pounds in weight.

One thing more, worthy of consideration, is that a horse, if worked at his maximum working power, would not last for any great length of time, while the tractor engine is made to run at nearly full load the entire period of its natural working life, which will vary as some tractors are built better than others, and again some will be abused while others receive excellent care, and upon these things depend the length of service we may reasonably expect from them.

H. W. SWOPE.

HOOF OF THE FARM HORSE.—THE KIND THAT GIVES GOOD SERVICE

The shape of the healthy fore and hind feet of the horse are inclined to be eoval, but the fore foot when well formed should be almost circular. In the forefoot the breadth is usually greatest from side to side; in the hind foot the width is greatest from the front to the back. When the forefeet have a tendency to become like the hind feet, they are called contracted, with high boxy heels or muley feet. This is an unnatural form of hoof and any long-continued lameness which prevents the horse placing the usual weight on the foot or feet, may cause contraction. This fact should cause considerable suspicion, and call for more careful examination. A certain amount of contraction may have been caused by faulty shoeing—cutting away the bars of the foot; paring the frog so that it does not come in contact with the ground; neglect or rasping the horn of the quarters, and lowering the heels, thus preventing the expansion of feet to their healthy size and shape.

There is no reason to reject all horses with "wired-in" heels provided the horse goes sound. Contraction is not always accompanied by lameness. When the contraction takes place slowly, the bones of the foot accommodate themselves to the altered conditions.

Then as to flat soles, the weight of the body ought to be kept well above the ground surface of the foot, which should be arch-shaped; hence, the use of wedge shoes, or calking, are an evil if occasionally necessary. The cause may be congenital, due to laminitis, or abuse of the drawing knife. The degree of flatness varies much and the propriety of purchasing depends upon iit. The flatness may be just perceptible and made less noticeable by the use of the drawing knife giving a ficticious dome, but this can be detected by pressing the sole rudely and noticing if it yields or if the horse flinches.

The large flat-footed horse is frequently found with brittle hoofs, rendering the task of the farrier more difficult and it has been found that the large flat-footed animal has often a weak constitution, succumbs readily and recavers badly from febrile contagious diseases.

Of the two evils from faulty shape the muley foot is the least to fear. Low heels are undesirable; they are frequently associated with tenderness, corns, and long oblique pasterns. Long toes from wearing the shoes too long, throw a strain on the back tendons, and should lead to a careful examination of these and the ligaments before purchasing. A too oblique pastern is to be avoided, but upright, short pasterns are most undesirable in the horse; the jar, the stilty gait, and the so much weight thrown upon the structures of the feet have the result that sooner or later they will be the seat of disease, and for saddle

Limited
MONTREAL

purposes this shape is totally unfit. Toes turned out, from badly-formed legs, should never be bought for fast work; such horses are every liable to brush and tobruise the fetlocks and the ligaments, besides leading to enlargement of these structures. The opposite condition, inturned toes, is not perhaps, quite so much of an evil, but a horse with this shape is apt to be a "digger" and stumbler. Both these conditions are congenital and shoeing cannot modify them appreciably.

BALKERS AND HALTER PULLERS

Of all vices that equine flesh is heir to the most annoying to the average horse owner and driver is balking, or near balking, which consists in rearing or plunging when first asked to start, particularly after a rest of a few days, or, what is still worse, trying to start with a jump when only half hitched. The main reason that I think it is so aggravating, is that so few know how to combat it. A balky horse has the most sense, the confirmed runaway the least of any horse. I have bought more balky horses than those with any other vice for that reason. Once they are broken of balking they make the best of horses, being not afraid of the objects that usually scare those of different temperaments.

The little simple trick I am going to describe, and that has proved so satisfactory in so many cases, it not intended to break the horse of balking, which in most cases involves a lot of time, patience and more or less thorough knowledge of horse nature, but rather to help those who have been caught perhaps with a new horse that started away from home all right, but has now balked because the conditions under which he has balked before have again presented themselves. The average driver when caught in this way starts in by petting and coaxing the horse and winds up by losing his temper and beating it until stopped by passers-by or some policeman.

A horse has only one idea in his head at a time, and in this case he has decided not to go any further with that particular load, and the coaxing and petting are not sufficient to cause him to think of anything else. Whipping only makes him more stubborn and determined not to move. Now we have got to find something that will give him something else to think about.

All horses hate to have their ears hampered. In fact, no horse ever decides upon a different course of action without first moving his ears from the normal position, and here is the key to the whole idea. As soon as he balks, get down from the seat and deliberately take one ear and push it under the crown piece of the bridle, so that it is fast and leave the horse to his own devices for a few minutes. He will commence shaking his head and doing everything he can think of to get that ear loose, until he has forgotten all about balking and his whole thoughts are centred upon freeing that ear. Now let the driver get back on the wagon, call on the horse to start, and off he goes. Leave the ear where it is for about twenty minutes, then stop and free it. Let the horse have time to shake his head and be satisfied that everything is all right again, and off he will go as pleasantly as possible. As I previously stated, this trick will not break a horse from balking, but it will invariably start one that has balked on the road, provided he hasn't already been whipped and abused to a point where nothing matters.

The vice of halter-pulling is a very troublesome one, but I believe that any halter-puller can be cured of the habit. Any one of the following named methods will give good results. Take an inch rope, fasten a good heavy ring in the end to make an easy-running noose. Put the rope around the body of the horse just in front of the hip bones, that is, around the flanks. The ring should be under the belly. Now take the loose end of the rope, bring it up between the front legs and through the halter ring. To tie out-of-doors, tie if possible to a strong, springy limb of a tree or a small tree that will spring some when the horse pulls back. Repeat this treatment until the horse ceases to pull back, whenever you have occasion to tie him, whether in the barn or out-of-doors. Do not forget the ring, so when the horse quits pulling an jumps ahead the rope will loosen, and be sure to tie him whether in the barn or out to something he cannot break.

Another method is to tie a rope around the horse's neck and run it through the halter ring, then through a large hole in the manger, and fasten the end of the rope around the left front foot below the fetlock, letting the rope be long enough, so that he stands natural. When the horse pulls back he lifts the front foot off the ground, and in order to put it down again he has to step up. He may be left tied this way all day. A stran with a ring in it should be used around the pastern to tie the rope to. The horse may also be hitched to the hitching rack if a large staple is driven in the rack on the opposite side from the horse to pass the rope through freely and keep it from slipping sidewise. It doesn't take long to cure a halter-puller by this method.

Here is an effective cure for a persistent puller. Put on an ordinary halter. Have a rope long enough to run from the halter through the hole in the manger or hitch rack and then through a pulley in the barn ten or twenty feet from the ground. The rope must be long enough to go from the halter as described, through the elevated pulley and down to the ground. Now tie a 100-pound weight on the end of the rope, allowing the horse about two feet of slack at the halter when the weight is done. A horse can thus be tied anywhere outside where a pulley can be elevated so he will learn to stand with a slack rope, as he finds he cannot break loose and the weight is on his neck every time he tightens the rope.

Another method is this. Take about thirty feet of half-inch rope, put it under the tail close up like a crupper, and cross it on top of the rump. Pass the ends through the halter ring, then tie to something solid, and let the horse pull. He will be very much surprised after he makes one trial.

THREE-YEAR-OLD MARE HAS LYMPHANGITIS

I have a three-year-old mare suffering from a badly swollen leg. It is paining her, and has every appearance of lymphangitis. What can I do for it?
W. A. R.

The symptoms of the disease you describe indicate inflammation of the absorbent vessels of the hind legs. It may extend to the cellular tissue, become chronic and produce effusions and permanent swelling of the leg. It gets the names of lymphangitis, weed, or shot of grease, and is generally attributed to high feeding without sufficient exercise; over-feeding of green food or intestinal irritation of various kinds. Large coarse horses with thick legs are particularly subject to it. Horses that have been once attacked by this trouble are liable to a recurrence of the malady, time after time, until the limb assumes permanently an enlarged and distended condition, injuring both their appearance and usefulness. Keep your mare free from cold draughts of air and give her a moderate purge, consisting of a drench made of six drachms of powdered aloes, and a tablespoonful of powdered ginger in a pint or so of water. Foment the leg well with cloths wrung out of hot water, keep the bowels loose, and give as a drink an ounce of saltpetre in a gallon of water two or three times a day. To prevent the condition of "thick leg" that many times result from repeated attacks, rub the leg with a stimulating mercurial ointment made as follows: Red iodide of mercury, one drachm; lard, two ounces. A piece the size of a walnut should be rubbed into the swelling every day.

HORSE HAS MANGE

I have a horse that has a skin disease over his entire body, especially in the long hair on legs, tail and mane. The skin is persistently dusty and the hair tends to come out. What can I do to get rid of the trouble? W. H.

There is every indication that your horse is suffering from mange. Of all the skin diseases on horses this is by far the most to be dreaded on account of its contagiousness. Any animal that has it should be shut off from all others, and active measures taken to clean thoroughly every blanket, every piece of harness, brush, curry-comb or other utensil that has touched him. tSall posts, mangers, gates, rubbing posts and trees should be carefully washed with hot water, and carbolic acid or similar disinrectant or lime washed. Whatever remedy is applied the horse the parts should be washed with warm water and soap, to remove the crusts, dirt and scabs, before ointment or curing application is administered, otherwise it will not reach the insects that burrow in the skin. The following ointment will serve to eradicate the trouble if persistently applied. Flour of sulphur, two ounces; ten ounces of hog's lard; half an ounce of carbolic acid, mixed together. Wash the animal thoroughly every time and also dry it well before every application of the ointment.

POULTRY.

THE NOVA SCOTIA FIRST ANNUAL EGG LAYING CONTEST

To be held at the Poultry Department, Agricultural College, Truro, N. S., commencing November 1st, 1919 and continuing for eleven months until September 30th, 1920.

Rules and Regulations

This competition will be known as ——The First Nova Scotia Annual Egg Laying Contest. tI will be conducted on the Poultry Department of the Agricultural College, Truro, and under the direction of the Superintendent of Poultry and Manager of the Poultry Department of the Agricultural College.

Board of Management.

The Board of management will be Superintendent of Poultry for the Province of Nova Scotia and Manager of the Poultry Department of the Agricultural College, a Superintendent for the Contest (to be appointed) and Mr. H. H. Hull, Glace Bay, President of the Nova Scotia Poultry Association together with Mr. W. W. Osborne, New Glasgow, and Mr. John R. McMullen, Truro, N. S.

Scope and Number of Entries

The Contest will open to the Province of Nova Scotia. It will consist of 30 pens of five females—hens or pullets. The first 30 bonifide applications received accompanied with the entry fee will be the thirty accepted. Contestants will be privileges to maintain throughout the year a full complement of five birds. No males will be included.

No reserved birds will be required or accepted, and held subject to the loss of any birds in given pen. The owner, therefore is requested to have in readiness reserved birds which can be immediately shipped upon notification of the need of such a bird in any pen. In other words the owner will be given the privilege of maintaining a full number of 5 birds in the competition pen throughout the duration of the contest.

Fees

The entry fee for each pen will be $5.00 which must accompany the application. Applications are to be made on the printed form supplied with rules and regulations. All entry fees will be used for prizes in this competition.

Prizes

Suitable prizes will be awarded to the winning pens.

Delivering the Birds.

The birds must be delivered at Truro, express prepaid, between the first and fifteenth of October, 1919. The shipment should be addressed (Laying Contest) Poultry Department, Agricultural College, Truro and must also have the name and address of the shipper plainly marked on the shipping crate.

Rejection of the Birds.

Any birds arriving in a sick condition may at the discretion of the Contest Superintendent be rejected and either destroyed or shipped back to the owner at his expense. None but pure bred birds will be accepted and only those breeds that lay a marketable sized egg will be permitted to enter contest. The Superintendent also will have the right to clip the wings of any birds that may prove troublesome. No person connected with the Agricultural College, the Agricultural College Farm or the Department of Agriculture will be eligible to make entries. The right is reserved to refuse any and all entries.

Standard for Judging.

The rating of the birds or pens will be determined by the number, together with the size, the uniformity and marketing value of the eggs. The Canadian Standards for eggs will be used in rating the value of the eggs. The cost of Production will also be taken into consideration in rating the standing of the pens. All eggs produced will be retained by the management and sold to help defray expenses of this competition.

Feed and Care

The birds while in the contest will receive the best of feed and care but this will be subject to the judgment of the Board of Control. Each contestant will be entitled to the record of each bird he has in the contest and to a statement showing the receipts for eggs and expenditure for feed, etc. for his pen for the eleven months. Any birds in the contest which can qualify for the Canadian Poultry Record of Performance will be provided with pens to complete the 12 months test required.

No person except Officials of the contest will be allowed in the pens or yards after the birds have been housed. Every effort will be made to keep the birds quiet and no interference with them for the feed will be permitted. All pens will be trap nests during the contest. A detailed printed record will be presented to the contestant at the conclusion of the contest. Weekly reports will be sent to each contestant and complete monthly records will be prepared for the press.

Housing

The contest will be housed in double colony houses, 12 x 12 feet, divided into two pens having glass and cotton fronts.

The houses will be placed on the Poultry Plant of the Agricultural College on a plot of ground East of the main Poultr Building and will face the South. Each pen will be provided with a ard 20 x 50 feet.

Reports

A summary of the standing of each pen in the contest will be compiled at the close of each month, a copy of which will be supplied the owner of each pen. The co-operation of the Local and Provincial Press has been solicited and regular reports of the contest and its progress will be provided the papers that will publish it.

Return of the Birds

If no notification as to the disposal of the birds has been received by September 1st, 1920, the birds on the completion of the contest will be sent by ekpress collect to the owners address from which the shipment was made. No competitor shall be permitted to withdraw any of the fowls during the period of competition unless permission is granted by full vote of the Board of Management.

Entry forms will be supplied on application by addressing Superintendent Poultry Department, Agricultural College, Truro. All entries will be accepted according to provision of these rules and each contestant agree to abide by the above mentioned rules and regulations.

Entry Form

To J. P. Landry,
Poultry Department, Agricultural College, Truro.

Dear Sir:

I hereby enter one pen of..... for the First Annual Nova Scotia Egg Laying Contest and enclose herewith $5.00 in payment of entry fee. I hereby agree to the rules and regulations governing this contest which I have read.

MARKETING OF POULTRY PRODUCTS

(Experimental Farm Note)

Marketing has much to do with the success or failure of any poultry plant. No matter how successfully the plant may be run if the marketing end of the business is not properly looked after the whole enterprise will sooner or later end in failure.

Every producer should get the best price possible for his products, and to do this it is necessary to pay particular attention to their quality, and the season at which the products are sold.

Eggs.—Eggs should be gathered regularly and often. All small and dirty eggs should be retained for home use or sold separate from the rest.

The eggs should be neatly packed—if for private trade, they are made more attractive if put into neat cartons.

The sooner the eggs are in the hands of the consumer the greater the satisfaction and consequently the better the price received.

ACADIA UNIVERSITY
WOLFVILLE - - Nova Scotia.
Departments
Arts and Sciences. Applied Science. Theology.
Degrees
B.A., B.Sc., B.Th., M.A., and certificates admitting to the best technical schools. First two years in Agriculture given as electives in B.Sc., course. First year in Medicine, Law, and Theology given as electives in B.A. course.
Special Courses
Courses in Surveying, Draughting, Shopwork, Chemistry, Electricity, and Bacteriology, for returned soldiers.
Equipment
Largest undergraduate faculty in the Maritime Provinces. Three new and splendidly equipped Science Buildings.
Expenses
Expenses light, and over $1,000.00 given in prizes and scholarships yearly. Send for calendar to
Rev. GEORGE B. CUTTEN, Ph.D., D.D., LL.D., President.
Next term begins October, 1st, 1919.

ACADIA LADIES' SEMINARY
WOLFVILLE - - Nova Scotia.
The Aim.—To prepare Girls and Young Women for Complete Living.
The Courses.—Twelve; including College Matriculation, General, Music, Art, Expression, Household Science, Business.
The Faculty.—Twenty-four Teachers of fine personality and Special Training.
The Equipment.—Modern and First Class in every respect
A Junior School.—For Younger Pupils.
Information.—Write for illustrated book to
Rev. H. T. DeWOLFE, D.D., Principal.
Next term begins September 3rd, 1919.

Acadia Collegiate and Business Academy
A Residential School for Boys and Young Men
Ninety-first Year
Courses. — Collegiate, Manual Training, Business, Special Courses.
Features.—Modern Residence, Good Equipment, Ideal Location, Splendid Environment. Experienced Teaching Staff, Moderate Cost.
For illustrated Catalogue of Information apply to
Principal W. L. ARCHIBALD, Ph.D.,
WOLFVILLE - - Nova Scotia.
Next term opens September 3rd, 1919.

Dalhousie University
Halifax, N. S.
Arts, Science, Engineering, Music, Law, Pharmacy, Medicine, Dentistry

ENTRANCE SCHOLARSHIPS:
Three of $200, five of $100, each. Awarded on results of matriculation examinations, September 24-27, 1919. One reserved for Halifax County, one for Cape Breton, one for New Brunswick, and one for Prince Edward Island.

FIRST YEAR SCHOLARSHIPS:
Three of $200, three of $100, each. Awarded on results of first year, and tenable during second year.

DORMITORY ACCOMMODATION
is being provided for men students. Work on Women's Residence has begun. Provision will be made for women students until new building is ready.

REGISTRATION DAYS
in all Faculties September 29th and 30th. Halifax students must register on the 29th

LECTURES BEGIN
October 1st, 1919.

FOR FULL INFORMATION
write to President's Office.

The pullets should be early so that production will be heavy. If at any time during season the eggs become so plentiful as to cause a glut in the market forcing down the price to the cost of production, it is often advisable to use a good preservative and put away the surplus for the period of scarcity which invariably follows.

Table Poultry.—Immediately following "the spring lay" the flock should be gone over and all useless cock birds and those hens that show they intend to rest for the summer, should be put into crates and fed heavily for a week or ten days and thei sent to market either live or dressed, according to market requirements. This culling should not all be done at one time but gradually, as occasion requires, but it should be the aim to get the culling over with as far as possible before the time for marketing broilers, as the prices for fowl alwas drop after that.

Broilers.—It will pay to market many of the early cockerels as broilers depending on those later hatched for roasters as the season advances. All cockerels of teh light weight varieties should be marketed as broilers. When they are eight to ten weeks old either crate or pen feed them for a week or two as to finish well before marketing.

Roasters.—In the general purpose breeds such as Plymouth Rocks and Wyandottes, the main crop of cockerels should be held for roasters. These should be crate fed for from ten days to two weeks or even four weeks, according to requirements. The most economical gains are made the first ten days to two weeks, but to get the best finish it will require three or even four weeks in the crates.

Aim to produce the highest quality product—

To market it in the best condition.

To ask and to receive the highest market price.

Write the Poultry Division, Experimental Farm, Ottawa, for circular on the Preservation of Eggs and Bulletin on the Marketing of Poultry Products.

KILL THE ROOSTER

Every year there is a great and needless loss in the egg trade through allowing the rooster to remain with the hens after the season for chicken hatching has passed.

It is now well known that flocks of hens that are unaccompanied by roosters will lay as many eggs as these same flocks would lay if roosters were among them.

But the fertile eggs laid by the flocks in which the roosters are present are very easily spoiled by the summer heat, while this heat does not affect infertile eggs.

It is estimated by Mr. J. E. Bergey, Poultry Specialist for the Agricultural Extension Service of Manitoba, that over one hundred thousand dollars is lost each year by permitting the roosters to run with the flocks after they should be separated from them.

Mr. Bergey says:

"Five eggs out of every 100 are spoiled because they are fertile. It takes 103 degrees to hatch a chick from a fertile egg, but a temperature of from 70 to 90 degrees may start enough life to spoil it for food. This will not happen with an infertile egg.

"There is a great demand for Canadian eggs in Europe. Manitoba poultry keepers must help to supply that demand.

"The rosters will bring more money in June than they will in the fall. Sell them and save food."

On almost every farm there are one or more roosters at this time of year. In a few cases these are pure-bred, expensive roosters that owners wish to keep over until next year. Such a rooster should be separated from the hens, until the cool weather comes on, when fertile eggs will not spoil with the heat. About three or four months will suffice. But in most other cases the owners are not intending to run the same roosters with the flocks next year; and in all such cases these birds should be sold or killed at once. It will not pay to keep them until autumn.

SELECT YOUR BEST LAYERS

Everyone knows that some hens lay much better than others, but not everyone kho weeps hens has the time or equipment to figure out the exact difference between a good layer and a poor one.

Professor M. C. Herner, head of the Poultry Department, Manitoba Agricultural College, has some very startling figures in this conenction as a result of using trap nests and keeping careful records. In one season, out of 325 pullets there were a hundred that laid over 100 eggs. Of these there were 25 that laid over 175 and 4 that laid over 200. Of the remaining hens that laid less than 100 eggs, there were some that laid only 3. There were even two that did not lay any eggs at all.

Now, a poor layer eats just as much, or nearly as much, as a good hen and takes up as much room and gives as much trouble. It is obvious that if you are keeping hens at all, it pays to keep the kind that will lay well.

There are certain points to look for in selecting good layers, assuming that you can not use the trap nest system and determine the matter accurately.

1. As a rule poor layers are fat, lazy hens. 2. Poor layers molt early in the summer. 3. They sit on the roosts late in the morning and go back early in the evening. Good layers, on the other hand, are bright, vigorous, active hens, working and scratching all day long. As a rule heavy layers molt late in the season in September, or even as late as October.

There are other important points to note in selecting good layers, such as the fact that in yellow-legged breeds; poor layers have legs of a rich yellow coyor while the good layers have legs of a paler, faded yellow. In heavy layers too, the pelvic bones are much farther apart than in poor layers.

PREVENTING LOSS OF FARM POULTRY

The annual losses in poultry flocks from preventable diseases must be enormous. On the general farm the loss of an occasional hen causes no discouragement and no effort to remedy the case. Of course, hens are subject to a certain death rate that cannot be prevented but it seems as if the farm poultry flock often suffers a mortality rate that is far more serious than is necessary.

Lice and mites are responsible indirectly for many losses. These pests sap the vitality of the fowls and reduce their resistance until they become subject to colds and roup and other diseases which might skip the healthy fowls. The cure for lice and mites is almost too well known to repeat. However, it should be emphasized that many farmers who know the cure do not take time to apply it and prevent their valuable flocks of fowls from being ruined by mites and lice.

A dislike to using the axe on a sick fowl often results in the contagious spreading. A bird may have its head swollen with a bad cold until its eyes are nearly shut. It should be isolated for treatment but too often it is allowed to go without treatment and sometimes it is carefully treated but placed back in the flock where it can infect other birds. Colds are very contagious and they not only temporarily cause discomfort to the bird but they reduce its vitality and about destroy its value as a breeder. A bird that has suffered from a severe cold is more apt to have another cold and we also feel that it is apt to transmit a susceptibility to colds to its offspring.

If a bird is very sick and not of unusual value it often saves time, worry and the risk of infecting other birds if the sick fowl is killed and burned. The burning of the infected bird prevents the body being dug up by a dog and left somewheer on the farm where the hens have access to it. If a diseased fowl is buried it should be put down far enough to prevent its being recovered by the scratching or rooting of the animals.

NON-LAYING HENS

When a hen frequents the nest without result, it is a sign that there is some obstruction in the oviduct preventing the production of eggs which the hen would not go to the nest. As a rule, the obstruction is a mass of congealed eggs which originally came through broken eggs in the oviduct, and when this collection is a large one it is not possible to do anything to help the hen to pass it, but when only a few broken eggs have collected, a good dose of warmed castor oil, followed by several of salad oil, is generally effective. A desertspoonful is the dose for a hen in this condition, and you would do well to try this treatment without delay. You may also help matters by holding her over a jug of really hot water, so that the steam permeates the passage, as this causes the parts to relax, and the hen is assisted in getting rid of the obstruction.—Australian Agriculturist.

POULTRY HOUSE LITTER

The health of the farm poultry bock is influenced by the quality of the litter in the house. When the straw becomes damp and dirty it should be removed. The ventilation of the poultry house affects the poultry litter. In houses with plenty of open-front and windows, the fresh air and sunshine help to keep the litter dry. It is almost impossible to keep the litter in good condition without sunshine and so in a damp and dark poultry house the difficulties of managing the flock are apparent.

A little time spent in removing the trash that settles to the bottom of a ditch or run will very often save a lot of trouble and one of the best tools for that work is a potato hook. Grass, weeds, leaves, etc., that sink to the bottom or pile up in a ditch or run can be drawn out much easier with a potato hook than with a hoe or shovel.

MOUNT ALLISON LADIES' COLLEGE

Founded 1854. Session 1919-20

OPENS SEPTEMBER 8

¶This is the largest Residential Ladies' College in Canada.

¶WE STAND FOR—High Ideals, Soul Culture, Intellectual Equipment.

¶WE GIVE COURSES in—Music, Oratory, Household Science, Literature, Fine Arts and University Matriculation. Business Courses are provided by the Academy Affiliated with us.

¶WE POSSESS—An enviable reputation of almost continental scope.

¶Our Art Museum is a feature where we consider we stand without a peer. Free Calendar on application to

Rev. HAMILTON WIGLE, D.D., Principal

SACKVILLE, N. B.

MOUNT ALLISON UNIVERSITY

Annual Session 1919-20

OPENS SATURDAY SEPT. 20

¶Many Scholarships and Prizes are offered. For information regarding Courses of Study, Degrees, Scholarships, Prizes, Affiliated Relations, Expenses, etc.

SEND FOR CALENDAR

¶Incoming Students wishing Residential Accommodation—for which MOUNT ALLISON IS JUSTLY FAMOUS—should give earliest possible notice.

Courses in

ARTS, SCIENCE, AND THEOLOGY

Rev. B. C. BORDEN, D.D. : President

SACKVILLE, N. B.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N B. solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

Guard well within yourself that treasure, kindness. Know how to give without heistation, how to lose without regret, how to acquire without meanness.—George Sand.

"GRINDSTONE OF LIFE"

Hannah Jones was hurrying. She always timed herself by the clock and the work under hand was taking her a good deal longer than her alloted time for it, and she hal been obliged to stop in the midst of it to tie up a badly cut finger for Johnniie, and even after it was proprely fixed, he had fretted and whined in an unusual way, so she had felt compelled to spend a few minutes with him. At last she had found something to amuse him, and he was forgetting. She was piling up in her mind the tasks yet to be done. Her allowance for her housework never allowed for loitering, nor made way for the interruptions that occur. That was the rock upon which Hannah Jones split usually, and she had worked herself into such a state of nervous exhaustion she felt ready to drop when dinner was once on the table.

"What's the matter, Hannah?" John asked pleasantly.

"Oh, I can't work fast enough; I can't work half as fast as I can plan, and even if I could the plans won't work out," Hannah said raspingly.

"Well," agreed John sympatheticall-ly, "your rules are made of cast iron; they won't bend. First thing you know you'll break, if the rules won't.

"Oh, that's all you know about it," she snapped. "You keep your hired man all the time, and if any extra work comes up you get another man, and so you manage al lright, but no matter how many extra men you have I don't have any extra women to help me."

"But Hannah, you might have," John interpolated, appealingly.

"I don't want any extra ones. They just make that much more work. Here we are four in the familiy now and if I had a woman she would make one more and her being here would, in all reasonable calculation, make one-fifth more work for us both to do. Yes, it would be more than that, because she'd make emore washing and ironing and she'd probably want to sew for herself and have a day off Sunday—the day I am the very busest of all—and, maybe, bother the hired help so they'd want to chase off to doings at night. It's always worked that way. And then, too, they never try to see how much they can get done. I can do my dishes in almost half the time it takes the help I've had to do them. If I've got to stand over help with a club to get anything done—why, I'd rather do it myself. The nervous strain of having help around takes more out of me than the work itself does."

"Well," suggested John, "couldn't you put some of the work out to be done, or use bakery stuff to piece out with——"

"Well, when I put the washing out, how has it come back? Some of it hasn't come back at all and some that did come back was torn and spoiled and other pieces were only about half washed, so I had to do them over."

Hannah Jones was fully capable of doing about three things at a time. She had dished up the dinner, rushed around collecting the chairs, poured tea, pretended to eat and talked and did all these things at almost one and the same mament.

"Well, I wish you would let up some. Maybe you can think it out yourself. I can't. It's all I can do to manage my own affairs." So John dismissed the matter.

"Hurry and get through your dinner, I've got to catch up. I'm losing time al the time," Hannah spoke nervously. She prided herself on being systematic. Every day had its work and if anything kept her from doing her alloted tasks on the day and hour set for its special accomplishment she was wholly at a loss.

On this day a man came to see John, and as he arrived after dinner was under way he was invited to eat with them. Hannah felt like slaying him, but he smiled at her so pleasantly and apologized so sincerely she could hardly do less than serve him, with at least a semblance of cheerfulness.

"You see, Mrs. Jones, it was this way. I knew John wouldn't be here until dinner time, and I knew he wouldn't want to lose any time to talk the business over, so I seemed compelled to make myself an unasked guest rather than miss the opportunity of seeing him at his only leisure moment—if it is leisure when dinner is in process."

"You're welcome," returned John. "Take that chair. It's luck you came when you did or you'd have had no dessert. Hannah always cuts the pie according to the number of people to be served."

"Rather generous service," laughed the hand, "had you ben alone." And he looked approvingly at the luscious black raspberry pie awaiting cutting near Hannah's right arm.

Then the talk turned to the matter of business, and the men ate slower and slower and finaly pushed back a little, but still kept talking and figuring. Hannah was on nettles, but she realizeed that she couldn't interfere or interrupt. The business deal was one John wanted consumated. It would be of definite value to all concerned, and it was brought to a finish in an hour's time. But this lost hour piled on to the time lost during the forenoon loomed so large to Hannah Jones, tired as she was, that she felt she could hardly face the race with time and work necessitated by keeping her "system" of work intact. Hannah, however, was a gallant worker, and she wrestled with the things to do. She knew too, she could steal a few hours from her night's rest if she had to. But it was decreed that she should not catch up. A friend from "way off" came —and she could stay just over one train—and Hannah simply gave up.

"Goodness, Hannah! In your kitchen this hot afternoon?" Helen Hand exclaimed.

"Yes," Hannah returned. "I really do have a system of work, and I keep up to it ordinarily, but things have kept interfering. If it hasn't been one thing it's been two—and so here you find me."

"I'll help you," Helen offered, cheerfully.

"No," Hannah demurred. "I've got to the place where I can't go another minute. I've got to stop."

"And do you let yourself get to the place where you've got to stop very often?" Helen asked, curiously, looking at Hannah's nerve trembling hands and lips that twitched and quivered at the corners.

"Oh, no, not often, because mostly I can do my work in the time set for it, but on days that work wrong I get just frantic, though I never do stop on that account. I'd be more frantic than ever if I stopped and let the work pile up. It would be like ocean waves that pils up until they get mountain high."

"Yes," agreed Helen, "they do, and what then? They collapse, and that is what you'll be doing first thing you know."

Hannah looked at Helen curiously. "Don't you have set times for set work?" she asked strangely.

"Not any more," Helen returned, smiling. "I used to be just that way. I worked and timed myself for everything. I set myself 'stunts' to be done, and done just so, in just such a period of time. I counted everything, even found myself trying to count the words I read. When I reached that point I decided it was time to quit. I made myself do things haphazardly. I did really see that the meals were on time, that my family was fed and clothed and washed and ironed, but I stopped timing myself. When I began to feel as though I must simply kill myself rushing I sat down and crocheted awhile or turned on the phongraph. Really, it seems as though I never did my work so easy as I do now that I take it easy, with a little pleasure thrown in between tasks."

"So many mornings I get up feelin gas though I simply couldn't do things," Hannah lamented.

"When I feel that way I see that the breakfast is served, but I don't fuss to bake muffins or waffles or griddles cakes those mornings; I fix something easier. If I still feel that way after breakfast I let myself do exactly what I want to do. If I want to go back to bed I do it, and I stay as long as I want to, and I find when I get up I can work much faster and that I really do keep things up just as well as I did when I kept on a perfect racecourse of running. It isn't the work that wears us out. It's the stewing and the nervous strain."

"But what if somebody comes and finds the work all at loose ends?"

"I don't make eexcuses. I am my own master and the master of my work. Many days I can go on in the steady trend, but when I find myself getting wrought up, nervous, tired, and fretful, I relax, and I'm never going back to the laws of the Medes and Persians—which didn't alter, you know, though they killed a few to keep them intact."

"Hm!" said Hannah lucidly.

"What's the ruction?" inquired John a month later, when he entered the house after breakfast to find Hannah ensconced luxuriously in a rocker, with the phonograph playing. Hannah was crocheting.

"Nothing," aHnnah returned laughing. "I'm just being master of my work instead of letting it master me. When it gets at me with a club I sit down and won't do a thing. I'll teach it yet, that I am master. And she laughed heartfily.

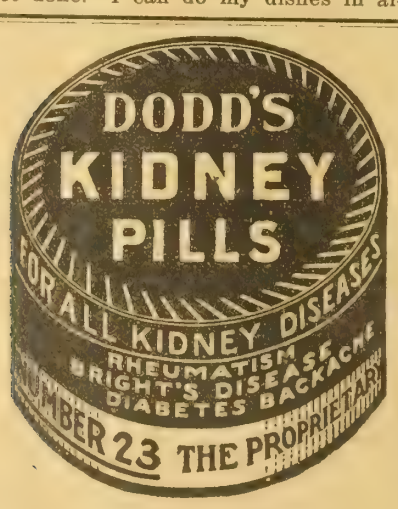
"Huh!" returned John expressively. "Master of your soul, eh? That's good. I've always thought your nose too good to be ground down with the wheel of life, but you seemed determined to be a martyr."

"I'm not a martyr any more, and I'm not going to serve you up at the stake either. I enjoy my work now, and I enjoy life, and I want you to do so too, John."

"I'll admit you did pretty nearly make a nervous wreck of me, but just because I worried about you. It's a might good thing to live to work instead of working to live."

"It isn't overwork that kills women, it's worry and watching the clock, and timing themselves. I like things right, but it's better to be than to do."

"It is," agreed John, "and you're being simply adorable lately, just like you used to be.



CANNING HENS FOR WINTER USE

"Canned chicken" may be made at home in your own kitchen out of the old hens that ought to be killed anyway.

The method operation for what is known as "Straight Pack" by the trade is very simple and is given in detail as follows by Dr. Robt. Barnes, Chief of the Meat and Canned Foods Division, Health of Animals Branch, Department of Agriculture, Ottawa.

Clean and cut up the chicken.

MAGIC BAKING POWDER

Contains no alum

We unhesitatingly recommend Magic Baking Powder as being the best and purest baking powder possible to produce. It possesses elements of food that have to do the building up of brain and nerve matter and is absolutely free from alum or other injurious substitutes.

SICK HEADACHES AND CONSTIPATION.

When the bowels do not perform their functions properly the liver is sure to become affected and the inactive condition of the liver will cause constipation, sick or bilious headaches, heartburn, water brash, specks floating before the eyes, the tongue becomes coated, the breath foul, and the eyes have a dull, yellow glassy appearance.

Milburn's Laxa-Liver Pills will regulate any irregularity of the bowels and stimulate the sluggish liver into action.

Mrs. Malcolm McDermid, Cranton Section, N.S., writes:—"I have been sick for a number of years with sick headaches and constipation. I tried all kinds of doctor's medicines but none did me any good. I tried Milburn's Laxa-Liver Pills, and after using four vials I am completely cured. I would heartily recommend them to all sufferers."

Milburn's Laxa-Liver Pills are 25c. a vial at all dealers or mailed direct by The T. Milburn Co., Limited, Toronto, Ont.

Sort out the fleshy portions, such as the legs, thighs and breast.

Break off the protruding portions of the bones in each piece.

Pack these fleshy portions in a gem jar or other container, as closely as possible.

Add salt and pepper. (About a teaspoonful of salt and ⅛ teaspoonful of pepper.)

Fill to within ¾ inch of overflowing with the liquid that comes from the balance of the chicken, process for preparing which is given beelow.

Place in boiler or other vessel containing warm water and gradually bring to a boil.

For pint jars boil 2¼ hours.

For quart jars boil 3½ hours.

For the balance of the chicken: Place in kettle and boil till the meat will strip free from the bones.

Strip off all meat and pack in jar.

Pour thereon the balance of the liquid in the kettle that has not been used in the first jar. If there is not enough liquid to fill the second jar, add water. Place in boiler as above, and boil as follows:

For pint jars 1¾ hours

For quarts 2¼ hours.

If desired the whole of the chicken may be prepared the same as the last part.

In all cases take care not to expose the gem jars to a sudden change of temperature.

Also, after the pars have cooled off, examine the tops to see that the covers are air-tight.

During the cooking of the product, place the glass tops on the sealers, but do not fasten them. Any steam or gas which may be generated will escape. As soon, however, as the process is finished, fasten the tops securely.

While desecribing the method of canning, something should be said about the poultry to be canned.

What is preferred are good, plump fowls, with a fair proportion of chickens, the bones of the latter giving a firmer jelly and lessening the danger of a soupy or slushy product. As a precaution against this condition, where the pack is straight fowl, gelatine may be, and often is used.

So much has been said and written about the proper methods of starving, bleeding and plucking poultry for market that it is useless to go over them again. One can only emphasize the necessity of exactness in carrying out the accepted principles in connection with these points, which are just as applicable to poultry to be canned as they are to those intended for the market.

There is another point which is important, although possibly its carrying out may detract from the appearance and affect the sale to an inexperienced buyer, namely, that all poultry intended for food, canned or otherwise, after being properly starved, bled and plucked should be left undrawn and kept in a suitable temperature for a day or two in order that the chemical changes which follow the killing of the bird may have an opportunity to take place.

"Is this the genuine Dr. Chase's Nerve Food?"

"Yes, madam, we do not offer substitutes, nor do we believe there is anything to take the place of this great nerve restorative."

"WELL, it has been so strongly recommended to me that I do not want to make any mistake in getting the right medicine."

"You are not making any mistake in this, for we think too much of our reputation to try to talk you into taking something else."

"Do you sell much of Dr. Chase's Nerve Food ?"

"It is one of our largest sellers, and gives such universal satisfaction that it is a pleasure to recommend it to our customers."

But do you know of cases in which it has actually cured people of sleeplessness, headaches, irritability and nervousness ?"

"Scores of them, madam. Some people never say anything about the medicines they buy, but scarcely a day passes that we do not hear of some case in which Dr. Chase's Nerve Food has effected a cure. It is also great for anaemia, and all ailments arising from a thin, watery condition of the blood."

"Well, I am going to try it. How much is it a box?"

"Fifty cents a box, or six boxes for $2.75. Better take the six, for you save a little on the price, and you need that many to give it a fair trial."

"Do you think I will."

"Oh, yes, the process of building up the nervous system is necessarily slow. You will no doubt feel benefited after the first box or two have been used, but too many make the mistake of neglecting the treatment then instead of keeping on until the nerves are fully restored."

"Do me up the six boxes, then, for I hear of so many people being benefited by using the Nerve Food that I am going to give it a thorough test."

If your dealer does not have Dr. Chase's Nerve Food in stock, write direct to Edmanson, Bates & Co., Ltd., Toronto.

THE BUFFALO MOTH

The buffalo moth, which resembles the lady-bug is the worst type of moth and hardest to destroy. The lady-bug is a small white beetle, oval in shape with black and red spots. The buffalo moth is a smaller beetle and not so oval in shape and are not so spotted and emits a disagreeable odor when crushed. It is not the moth but it is in the larvel stage and feeds almost entirely on woolens, The beetles feed on the pollen of flowers. It has been claimed recently that this moth is often introduced into houses through evergreens and other woodsy material used for decorative purposes. If you discover a small webby, white bunch resembling cotton here and there through the house, usually near windows, for it is there the beetle deposits her nits—you may safely conclude you have a case of buffalo moths. These little webby bunches no larger than the ned of one's finger, will be found to contain a lot of nits, which if not destroyed, will hatch and drop to the floor to begin their ravages . Each nest contains various sizes. The larger ones will hatch first but they are all fertile to a disagreeable degree. Where houses are kept at high temperature during winter months the buffalo moths can be seen on a sunshiny day. These moths should be killed before they have deposited their nits in the above named nests for from the nits the larvae hatch and begin their depredations. This is where the kerosene is used to best results and must be used in sufficient quantities to permeate the crevices. The room must be kept tightly closed and be thoroughly ventilated before using any remedy; and this is only "doctoring the effect." Ground spices, tarred paper, dried tansy and sweet flag or calamus are all good to use in putting away woolens and furs. Their odor keeps the moth from infesting those articles so badly. Moth balls are not beneficial with buffalo moths. The common moth is less destructive and easier eradicated than the buffalo moth.

I bought a horse with a supposedly incurable ringbone for $30.00. Cured him with $1.00 worth of MINARD'S LINIMENT and sold him for $85.00. Profit on Liniment, $54.

BEVERAGES

A beverage is any drink. Water, the chief one of them is Nature's drink or beverage. Almost all of the beverages have but little nutritive value. (Exception must be made, however, to egg-nogs, cocoa and chocolate.) Nevertheless their use in health as well as in disease should be carefully considered. When abstinence from solid food is necessary for a short time the patient must depend upon beverages for nourishment.

Starchy beverage include toast, rice and barley water. Rice and barley water are given to reduce a laxative condition of the bowels, and are often used alternately. Rice water is soothing to the whole alimentary canal. Toast water is given in cases of extreme nausea.

Fruit beverage are cooling, refreshing, slightly stimulating and are valuable for the salts, sugar and acids they contain. They are frequently employed when high temperature is present. Lemons and oranges are most used in making fruit beverages, chiefly because of their cheapness. As all fruits contain one or more acids, a physician should be consulted as to the kind to be given in individual cases. Pineapple contains a ferment that digest proteins.

Wine whey is stimulating, and is often retained in severe gastric ailments. For a limited period it may be used for debilitated infants with a weak digestion. It stimulates the digestive ferments to such an extent that there may be a gradual return to the regular diet. Clam water and oyster liquor some times stimulate the appetite. Clam water administered in small quantities, is especially valuable in relieving extreme cases of nausea, in larger quantities it acts as a laxative.

Egg-nogs and other beverages in which eggs are used, play a most important part in the dietary of the sick.

Tea

The leaves of the evergreen shrub, Thea, furnish the tea of commerce, both black and green.

The best brands of black tea are imported from India and Ceylon. The best green varieties come from Japan and China. The leaves before curing have neither odor nor flavor.

There are four annual gatherings. The first, which comes in April is considered the best.

Climate, elevation, soil, cultivation, selection of the leaves and the care in the picking and curing of them all go to make up the quality of them. First quality tea is made from the young tender, whole leaves. In black tea the leaves are fermented. The leaves of gren tea are unfermented.

Tea is a stimulant not a nutrient. Its stimulating effect is due to the presence of an alkaloid, thein, and avolatile oil. Its astringent qualities are due to the present of tannin. Black tea contains less tannin than green tea. The thein and volatile oil vary but little.

Tea should always be made as an infusion by the use of freshly boiled water. The practice of allowing tea to boil, or allowing leaves to be used and reused with a small additional supply, cannot be too strongly condemned. The thein is so soluable that it is almost immediately dissolved out of the leaf. Tannic acid is dev eloped as soon as hot water is placed on the leaves but in a small quantity. Careful experiments show that more tannic acid is contained in a 5 minute than in a 3 minute infusion. The longer it stands the more tannic acid is drawn out.

Tea drinkers require less food than those not addicted to the habit, as it has been proved that there is less water to the tissues when it is indulged in. This accounts for the large quantity drunk by the poor. It would appear from its immediate stimulating and satisfying qualities that it had a food value; but when it is constantly used to take the place of food, evil effects are soon apparent, and the victim if attacked by disease, finds that his system offers little resistance. The harmful effects are due to the thein and oil, rather than to the tannic acid.

Tea, in moderation is stimulating, refreshing and often relieves bodily fatigue and headache. It has a slight influence in regulating temperature and circulation. It is cooling in summer and warming in winter. On an empty stomach it acts as a diuretic. Excessive tea drinkers are apt to become nervous, suffer from depression and insomnia. The habitual tea drinker often becomes a nervous wreck.

Coffee

Coffee is the seed of the berry of the evergreen tree CAFFOEA ARABICA, which yields annually three harvests. Each berry contains two seeds contained in a husk.

Coffee was formerly cured by being dried in the sun, but owing to frequent rainfalls in the country where it is grown slow artificial heat is preferable. It is imported to be cleaned, sized, roasted and ground. The coffee berry in its raw state has no odor nor flavor; both being developed by roasting.

Java coffee is the best coffee grown, but much coffee labelled "Java" does not come from the island of Java. Any coffee having the distinctive flavor of Java, no matter where grown, bears that name. Brazil, Central America, Mexico and Arabia are all coffee countries.

Coffee like tea is usuall blended, the most popular blend being 3 or 4 parts Java to 1 of Mocha.

Coffee is a stimulant as tea is. Its stimulating property is due to caffein and a volatile oil. The effect of caffein is almost identical with that of thein. It also contains tannin and is more stimulating than tea.

Coffee should be bought in small quantities and kept tightly covered in a glass jar or tin canister. It is best ground at home. Because of the large amount of volatile oil it contains it quickly depreciates in value.

Coffee may be prepared as a decoction (boiled coffee), an infusion or filtration. Coffee for filtering should be finely ground.

Coffee strengthens heat action and increases respiration. It is a nerve stimulant and acts as a diuretic. It relieves the sensation of fatigue and induces wakefulness. It is often valuable to relieve nausea after an anaesthetic, and often proves useful in cases of opium and alcoholic poisoning.

A cup of black coffee assists digestion but breakfast coffee with cream and sugar retards digestion.

When taken to excess coffee produces biliousness, languor restlessness, heartburn, palpitation of the heart, dyspepsia and insomnia.

Many preparations have been put upon the market as coffee substitutes, but to the coffee drinker there is no substitute. They, however, make a pleasing hot beverage. To the adult a single cup of coffee at breakfast and

UNSIGHTLY PIMPLES
PAINFUL BOILS
Are Caused By Bad Blood.

When the blood becomes impure, it is only natural that boils, pimples, or some other indication of bad blood should break out of the system.

Ointment and salves will do you no good You must get at the seat of the trouble by using a good internal blood purifying remedy such as that grand old medicine, Burdock Blood Bitters. This preparation has been on the market for the past 40 years, and is acknowledged by all who have ever used it to be the best blood cleansing remedy.

Mr. Emerson G. Goodwin, Cambridge, N.B., writes:—"For nearly two years I suffered from boils and pimples on my face and neck, and nearly all of my body was covered with the pimples. I tried most everything, but got no relief. One day a friend advised me to try Burdock Blood Bitters, and after using three bottles the pimples and boils had all left me, and there is no sign of them returning. I can strongly recommend B. B. B. to anyone who is troubled with skin disease."

Manufactured only by The T. Milburn Co.. Limited. Toronto. Ont.

a cup of tea at luncheon will not prove harmful.

Cocoa and Chocolate

Cocoa and chocolate are manufactured from the cocoa bean of commerce. This bean a native of Mexica, is the seed of a fruit 5 to 10 inches long, containing from 20 to 30 seeds. The area of the cocoa belt is limited, being confined to Mexico, South Ammerica, and the West Indies.

The fruit is gathered and allowed to remain on a heap on the ground for 24 hours. The pods are then cut open, the seeds removed, drained and put in a sweating box for 2 days to undergo fermentation. The flavor of the bean largely depends upon the care taken with this process. Now the beans are dried in the sun when they are ready for exportation.

Having been exported in this crude state they must now be cleaned, assorted and roasted; then the thin brittle covering removed by machinery. The thin coverings are sold under the name of "cocoa shells". The broken roasted beans constitute "cocoa nibs." Chocolate is the cocoa nibs crushed, pulverized and moulded. Vanilla and sweet chocolate have the addition of flavoring and sugar. In the manufacture of the various cocoas nearly one half the fat is removed from the cocoa nibs.

Unlike tea and coffee, cocoa and chocolate, though slightly stimulating, have a food value which should not be overlooked.

The stimulating effect of cocoa is due to theo-bromine, a principle closely allied to thein and caffiien; it also contains some tannin.

Cocoa as a beverage may be used by many with whom tea and coffee disagree. There are some however who find it clogging and heavy on account of the large amount of fat it contains. This is usually because it it taken with a hearty meal. In cases of enfeebled digestion cocoa usually agrees with the patient much better than tea or coffee.

Adulterations in tea and coffee are coloring matter, dried stems in tea and chicory in coffee. Starch and cocoa shells are the common adulterants in cocoa. Iron oxide is sometimes added to cheap articles for coloring purposes. Sugar is an adulterant inasmuch as it is a case of a cheaper material mixed with a more expensive one. Sweetened chocolate should always be properly labelled. There is really no adulteration of the brands of any reputation.

Cereal Coffees or Coffee "Substitutes"

These are NOT substitutes for coffee inasmuch as they do not produce the same effect and do not have the same flavor. They are harmless, the chief sin lying in the extraordinary claims made as to their nutritive value. As a matter of fact their nutritive value amounts to no more than the 1-20th part of skimmed milk; their chief value lying in the fact that they provide a hot, harmless beverage and restrict the drinking of the caffein bearing beverages. A good "decaffeinated" coffee is much better as it is harmless and has also the true coffee flavor.

When She Could Not Turn in Bed

DODD'S KIDNEY PILLS CURED MRS. WEBERG'S ILLS

Manitoba Woman After a Year of Suffering Proves Once Again that Dodd's Kidney Pills Help All Kidney Ills.

Rennie, Man., Aug. 3rd. (Special.)—"Yes, I feel as well as ever I did in my life and I give Dodd's Kidney Pills all the credit." The speaker was Mrs. E. Weberg, a highly respected resident here, who for some time was a severe sufferer from rheumatism and kidney trouble.

"My trouble started with a cold," Mrs. Weberg continued. "I coud not throw off the after-effects. My sleep was broken. I felt heavy and sleepy after meals and I was always tired and nervous. Stiffness in the joints, cramps in the muscles and then headache, backache and heart flutterings, followed .

"Then dropsy and rheumatism set in. I could not work on account of my sore back. I got so bad I could not turn myself in bed.

"I suffered for a year before I started to use Dodd's Kidney Pills. I used two boxes and now I feel as well as ever I did in my life."

Mrs. Weberg, who looks the picture of health, struck at the root of all her troubles when she used Dodd's Kidney Pills. All her ills came from sick kidneys. Dodd's Kidney Pills are purely and simply a kidney remedy. Their record for the last twenty-five years is the cause of their popularity. Ask your neighbors about them.

ICED COCO

¼ cupful flour, ½ cupful coco, 1 quart boiling water, ½ cupful sugar, ¼ teaspoonful salt, 1 teaspoonful vanilla.

Mix sugar, flour and coco. Add the boiling water gradually, stirring all the time. Place over the fire and cook slowly, 15 minutes. Add salt, and when cold put in the vanilla.

This syrup is the foundation for the coco drinks. If you have the time, it is better to add the hot syrup to a quart of scalded milk, let blend 15 minutes, then beat and chill. If using cold milk, blend the cold milk and the coco syrup with an egg beater. Serve with whipped cream and dust a tiny bit of grated sweet chocolate over the top of the glass. The syrup may be kept in the ice-box and used when desired.

Iced coco is an ideal summer beverage for all lovers of chocolate. It may be served with either luncheon or dinner, but it is particularly fitting to serve to afternoon "happen-in" guests.

ICED TEA

4 teaspoonfuls tea; 2 cupfuls boiling water.

Put the tea in a china or earthen pot and pour on the boiling water. Let steep where it will not boil but will be hot for 5 minutes. Pour off. If served at once pour into glasses filled with chipped ice, or if to be served later, pour into a pitcher. Many think the tea has a much better flavor if served as soon as made.

The tea is made strong to allow for the dilution of the chipped ice used in serving. Serve with slices of lemon or oranges, diced pineapple or strawberries. Clove may be put in the lemon slices, or a tiny piece of vanilla bean in the teapot for variety in flavor. Sweeten as desired with powdered sugar.

"You'll like the Flavor"
KING COLE TEA
Makes a Friend of Every User.
Perfectly packed in bright lead foil, and price marked on every package.

FRUIT PUNCH

1 pineapple or 1 can grated pineapple, 3 cupfuls boiling water, 1 cupful tea, freshly made, juice of 6 lemons, juice of 10 oranges, 1 quart strawberry, currant or grape juice, 1 bottle charged water, 1 quart sugar—or better, 2 cupfuls syrup, 3 quarts water.

Grate the pineapple, and boil with the water twenty minutes, or longer, then strain through a jelly bag, pressing out all the juice; let cool and add the rest of the fruit juice, the tea and the syrup. If sugar is used, add a pint of water to the sugar and let boil six or eight minutes; cool before using. Add the charged water just before serving. It is better to make the punch a few hours before the time of serving, then let stand closely covered, on ice, to chill and ripen. Then when ready to serve, add the water and the charged water. Strawberries, mint leaves, or slices of bananas or oranges may be added as a garnish.

ICED COFFEE

Allow at least 2 tablespoonfuls of coffee to each cup of water and make in any desired way. Pour at once from the grounds. The milk may be added while the coffee is hot or after it is cool. Serve with chipped ice and whipped cream. Sweeten if desired with powdered sugar. Iced coffee is a delicious "tea-time" drink.

READING ON TRAINS INJURIOUS TO THE EYES

Many people believe that it is injurious to the eyes to read on a train, but few seem to know why. The reason is the added strain on the delicate muscles of the eyes. The motion of the train shakes the paper or book constantly, thus continually changing its position and its distance from the eyes, keeping the delicate muscles of the eyes in constant action to readjust the focus. Extra work is thus thrown on these tiny muscles, as the changing of focus occurs sometimes a hundred times a minute.

Another cause of eye strain in reading on trains is the poor lighting usually encountered. Often people try to read on a train or street car when the daylight is fading and before the car lights are turned on. Even with the light on, the situation is not greatly improved. Usually the light is high up in the centre of the ceiling and is badly placed for reading, the light being too far away from the paper and the light rays being reflected into the eyes from the book or paper.

HELPS BY THE WAY

To prevent your white dresses from turning yellow when put away for the winter wrap them in blue paper. If you prefer to use white cloth dip it first in strong bluing water and it will serve the same.

When hanging pictures always hang them with the face to the wall first, then even up the wire and turn them without unhooking them. This leaves the wire twisted on the hook, and the jarring of the house will have no effect on them.

Nothing Better for Camp or Summer Kitchen

LENGTHENED LIFE FOR THE BATTERY

Batteries Like Tires Can Be Conserved By Intelligent Care

The period service of a starting and lighting battery is inevitably all too short. Never before in its history has the storage battery been largely used in such a strenuous and even abusive service as it now has to perform on hundreds of thousands of gasoline cars. Fortunately it is within the power of the user to somewhat mitigate the destructive conditions inherent in car service to a certain extent and thus give the battery a chance to last as long as circumstances permit and the following are suggestions directed toward the achievement of this end: Never let a battery become discharged and remain in that condition for any length of time, for the plates will become permanently sulphated, often beyond recovery. This applies especially to batteries on cars which are out of service, as when laid up for the winter, and need hardly be given in connection with batteries on cars, which are in regular use. When a battery is found to be discharged, charge it at once and keep it charged. Never allow a battery to be subjected to heavy overcharging, for any considerable period, as this abuse is more destructive than anything else to which it is likely to be subjected in normal service. Excessive overcharging is particularly dangerous to the users interests, as he is seldom warned against its evils by starting and lighting manufacturers, because it does not affect the operation of their apparatus, while undercharging does so, seriously. For this very reason such manufacturers generally adjust their systems for rates of charge that are too high to meet average conditions of use, in order to avoid the possibility of undercharging. The facts regarding overcharging are these: When a battery is fully charged, part of the current subsequently sent into it is wasted in decomposing the electrolyte into hydrogen, and oxygen, these gases being freed, with violence, within the active material of the plates, which is torn off and deposited in the bottom of the jar, where it may later collect and short-circuit the cell. The rest of the charging energy wasted in the battery is converted into heat, which often raises the temperature of a cell so high that the insulating separators are boiled into wood pulp, with the final result that the cell is short-circuited. When cells, that are not leaky, require more than very slight and occasional fillings with water or when they become noticeably hot, serious overcharging is taking place. The weather itself makes little difference in the water demanded, but it happens that batteries are more violently overcharged in summer than in winter, because of the difference in driving conditions.

Constant Overcharging Destroys Storage Cells

When it ras become evident that a battery is being habitually overcharged, as evidenced by its high temperature at the end of long drives and its large loss of water, the charging rate should at once be reduced. Until recently the regulation of charging rate has been made a mystery of, but now it is being mentioned more freely. The adjustment can be made on the generator of almost any system, in a few minutes and the car owner should insist upon its being attended to if he has any regard for his battery's longevity. Several different adjustments may be required in the course of a year's driving in order to meet changing conditions. Every time that the starting operation is performed, the battery is grossly overloaded. This ought to be generally realized and the period of overload reduced by insuring perfect carburation and ignition conditions. With care any engine ought to start in five seconds, summer or winter. Overloading tends to bend the plates and dislodge active material from the plates and for this reason accidental short-circuits should be carefully forestalled by keeping the insulation of the system in perfect condition. In refilling cells with water never use any that contains foreign matter as a very slight taint of metal will seriously injure the plates. Cells operate best when the density of the liquid is as prescribed and thus frequent hydrometer tests are essential. Since portions of the plates above the liquid do not enter into the normal chemical actions, they soon become permanently deteriorated, thus rendering it a vital matter always to keep them covered with electrolyte. The inevitable shocks of car operation are sufficiently hard upon a battery. They should be kept at the minimum by frequent inspections to determine that the battery is firmly secured upon the chassis. Batteries and tires are similar in one respect. They are the two elements of a car which have a relatively short life and which are known to require replacement at rather short intervals. The only thing that can be done with each is to try to make the replacement interval as long as possible.

SEEING ONE'S CAR AS OTHERS SEE IT

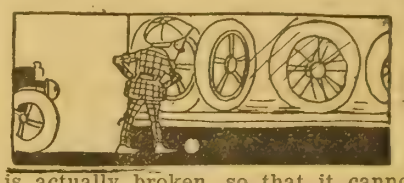
Do Your Wheels Run True and Otherwise Correctly,

Have you ever noticed how often the car ahead of you is afflicted with wabbly wheels? Sometimes, also, you may notice that the front wheels of other cars toe out instead of in. How are our own wheels? The operator seldom sees the wheels of his own car, while in motion, and it is well that he occasionally should let someone else drive and examine them critically, when his car is both receding from him and approaching him. A rim that does not run true subjects its tire to undue wear by "scuffing" is sideways over the road surface and there is also a tendency to loosen the rim fastenings and even the spokes. The wobble is usually caused by the careless application of the rim, resulting in its failure to seat properly all the way around. While a wheel is jacked up, for a rim change, the accuracy of its running should be tested. A bent axle shaft also causes a wobbling wheel, even though the rim is properly applied. A sagged rear axle housing or excessive wear in outside bearings results in rear wheels that run out of parallel and wear in steerinv pivots and bearings causes front wheels to lose their camber—their downward inclination together. Constant excessive change of direction of the front wheels of a car, approaching over a rough road, indicates abnormal play in the steering parts. A slight fluctuation of the front wheels, such as can be accounted for by the action of the springs in the drag link and allowable backlash in the steering column mechanism is permissible, but more than this causes abnormal front tire wear and even hard and possible uncertain steering control.

ARE WIRE WHEELS STRONGER?

J. S. M. asks: Are wheels with wire spokes stronger than those with wood spokes? Which last longer?

Answer: There still exists some difference of opinion upon this point, but it is pretty generally considered that, for the same weight, wire wheels are the stronger. In practice there is very little trouble from the breakage of either kind of wheel, except in accidents. When an accident does occur it is usually found that a wood wheel



is actually broken, so that it cannot safely be used, but with a wire wheel it often happens that, while it may be badly distorted enough of the spokes remain unbroken so that it can be used temporarily, after slight repairs have been made. Assuming that both kinds of wheels are kept thoronghly painted and thus protected from the weather, there is no practical difference in their life, but if they are neglected, it seems that teh wire wheel suffers more rapid deterioration. Repairs of wire wheels are usually cheaper than those of wood wheels.

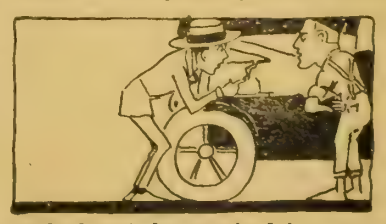
OPERATING CAR WITHOUT AMMETER

O. W. F. asks: Will it do any harm to run my car without the ammeter, which burned out and has been sent away for repairs? I have been told that the generator might burn out also if I did so.

Answer: If you electrically connect the two wires taken out of the ammeter, the system will work just as it did before the instrument was removed, except that you will have no indication of the current that is flowing, but should you run your car without connecting the ammeter wires together, the generator would run without furnishing any current to the system which, in the case of some generators, might result in the burning out of the shuntfield windings, under the very high voltage generated.

REPAIRING CRACKED WATER JACKET

R. R. S. asks: Can a crack in the outside of a cylinder, which lets wa-



ter leak out, be repaired in any way?

Answer: Usually it can. A small crack can sometimes be closed by "rusting it up" with salamoniac solution or by caulking it with copper wire. Most cracks can be filled by the autogenous welding process or by brazing and a properly fitted sheet metal patch screwed on over the break is sometimes used. The advice of a competent welder is of value in determining how such a crack may best be treated.

MAGNETO INQUIRY

M. J. B. writes: My 1915 car is equipped with a ———— magneto, which sparks the two inside cylinders simultaneously and the two outside cylinders simultaneously. It gives a good, fat spark, but an automobile

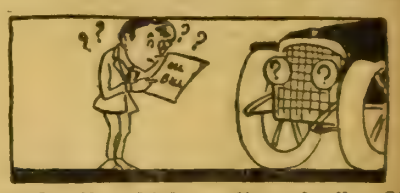
mechanic says that this arrangement is wrong and that I am getting only half the power I should. The valves of my engine are in good shape and the compression is all right, but it has no snap or vim. What is the matter?

Answer: This type of magneto proves perfectly successful in practice, the fact that two sparks, in series, occur at the same time, being taken account of in the design of the windings, so as to give ample igniting power. Its adoption permits the magneto distributor to be done away with, thus reducing the cost and complication of the instrument. If your particular magneto is in good condition you need not worry about the ignition. Very probably your trouble is caused by faulty carburation, assuming that everything is timed correctly. Since the date when your car was built, many changes have had to be made in carburetors and manifolds, in order to successfully utilize the increasingly involatile fuel furnished, and we believe that the application of exhaust heat to your manifold and the careful adjustment of the carburetor or the installation of a more modern one, will eliminate your troubles, assuming that there is no abnormal friction acting in any of the car parts.

LOW OIL ECONOMY

W. H. S. asks: What mileage on each gallon of oil ought I to get with my 1916 light six car? I have been figuring it up and I find that I have been averaging about 225 miles. Isn't this pretty low? If so, how can it be bettered?

Answer: Your oil economy is decidedly low. As a guess, we should say that you ought to be getting from 400 to 500 miles to the gallon, at least in warm weather, if your engine is well worn in and you are using the correct



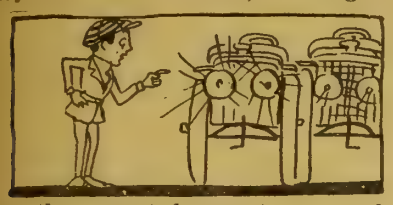
grade of a high quality of oil. Oil that is of a too light body, especially when hot, passes the pistons too freely and oil of a too low flash point is rapidly lost by decomposition. If fuel condensation is excessive, so that the engine oil has to be changed very frequently, the consumption becomes excessive. Badly fitted pistons and rings, leaks from the crank case, past defective gaskets or along bearings an the use of an illy adapted grade of oil are the usual causes of abnormal lubricant consumption.

TESTING THE FORD MAGNETO

W. P. P. asks: How can one tell whether a Ford magneto is as strong as it should be?

Answer: Most well equipped service stations, of this make of car, have a special voltmeter for testing the condition of magnetos and you can obtain one of these magneto testers from almost any Ford accessory dealer. Some idea of the condition of a suspected magneto can be obtained by comparing its action with that of one, known to be of normal strength, in another car of the same model and with the

same headlight arrangements. When the engines of the two cars are running at as nearly the same speed as they can be made to run, if the lights

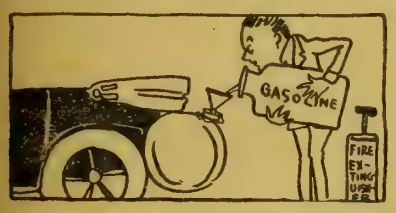


from the suspected magneto are much dimer than those from the other, a weakened condition is indicated.

FIRE DANGER FROM CHAMOIS STRAINER

J. H. writes: The instruction book that came with my car advises that all gasoline be filtered through chamois, but friends warn me that the use of this kind of strainer is likely to result in a fire. Is this danger a real one?

Answer: The danger, if it exists, is very slight and is entirely absent if the funnel used is of metal and touches the metal of the tank so long as gasoline is being poured upon the



chamois. In very cold, dry weather, friction of the gasoline upon the chamois may produce electrification of the funnel and a spark, if the funnel is not in contact with the tank. This has led to the passage of regulations against the use of chamois. We advise you to keep on with its use, taking the precautions above mentioned.

CYLINDERS FLOODED THROUGH VACUUM TANK DERANGEMENT

W. L. writes: Cylinders 3 and 4 of my "six" engine fail to fire. The sparks are perfectly good, but the cylinders seem to be flooded with gasoline, as I find the raw liquid there, when I take out the plugs. I think

that the trouble may be that the vacuum tank is working improperly. Is this probable?

Answer: Your inference is, in all probability, correct and your cylinders are receiving gasoline that is sucked from the tank through the top of the vacuum tank and, by way of the vacuum connection, right into the intake manifold of the engine. Most likely the float of the vacuum tank is prevented from rising, either by its having stuck or from its having become leaky and filled with gasoline so that it possesses no buoyancy. The air-vent is thus kept closed and the suction valve opened and when the upper tank compartment becomes filled with gasoline, it is drawn directly into the intake manifold when there is suction therein. Restoring the action of the float and its connected mechanism should remove your trouble.

Motor Efficiency Depends on Spark Plug Service

Spark Plug service depends on the ability of its insulator to resist vibration, shock of cylinder explosions and extremes of temperature changes in all types of motors, in all kinds of weather, in all climates, and under every known load and road condition.

Champion Dependable Spark Plugs

are equipped with our new 3450 Insulator, the result of ten years of tedious research and 3450 distinct experiments.

It offers three times the breakage resistance to sudden temperature changes; and

It has two and one-half times the breakage resistance to shock and vibration; and

It has fifty per cent. more resistance to electric current when heated than the best previous Champion Insulator that made the name a synonym for dependability.

Besides these Insulator tests, Champions are subjected to an air pressure test of 140 pounds to the square inch for compression leakage and a final inspection for imperfections. "Champion" on the Insulator is your guide to better spark plugs for efficient service in every make of motor or engine, each guaranteed to give "Absolute satisfaction to the user or full repair or replacement will be made."

Champion "O" for Overland Cars. A 14 "O" ½ in. Price $1.00.

CARE OF IGNITION CIRCUITS

Watch the Primary Connection and the Secondary Insulation

Ignition circuits are of two kinds, the primary and the secondary. The former is the circuit which comprises the battery, ignition switch, the coarse wire winding of the spark coil, the timer contacts and the wiring necessary to connect them. The latter circuit comprises the fine wire winding of the spark coil ,the distributor with its rotating brush and contact segments, the cables from the distributor segments to the several cylinders and the spark-plugs located therein. In the primary circuit flows a current of low pressure, usually of about six volts, while the secondary circuit carries a very high pressure (high tension) current, of tens of thousands of volts. Because of its low pressure, the primary current requires but a very slight obstruction to stop its flow. A loose or dirty connection at a wire end will do it. On the other hand, it has little power of escaping from its circuit and thus comparatively slight insulation will keep it from short-circuiting. The secondary current, on the other hand, is not affected by loose or corroded connections and will even flow, practically undiminished, through a slight break in a wire, but it has the power of jumping a considerable distance and where a "short sut" offers, it is likely to do so and fail to reach the spark-plug. It is evident from the above that the principal requirement in caring for the two circuits of an ignition system lies in keeping the primary circuit from becoming interrupted and keeping the secondary circuit so well insulated that a short-circuit cannot occur. In the primary, every inch of wire must be free from breaks, every wire end must be cleean and firmly secured to iits binding post, the switch must have no dirty or loose contacts, the timer points must be free from corrosion and the ground connection must be secure. In the secondary, every inch of wire must be free from dust and oil and the spark-plug insulation clean of soot and oil. It is useless to spend time cleaning plug points and tightening cable conection to plugs, with the fliers, dirt and looseness are of no account there. Keeping the plug porcelains clean and thus avoiding short-circuiting is the important matter.

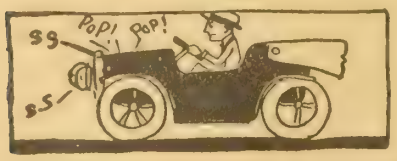
THE LIGHT TRAILER

The light trailer, for use behind the ordinary passenger automobile, has now become a recognized factor in motor car practice. As the motor car is now the "general utility" vehicle it is constantly being called upon to perform a rapidly widening range of services such as are constantly demanded in business and domestic life and the pneumatic tired, two wheel trailer has provided the response to this demand. The average automobile owner possesses but one—usually a passengar car— and this must be used for all his purposes. By fitting to it a light trailer, he can do trucking of goods which would spoil the interior finish if loaded into the passenger body, he can handle, on good level roads, a full body load and a full trailer load, without subjecting his car and its tires to more than slightly abnormal wear and tear and can render himself in great measure independent of express and railroad companies, by his ability to carry with him the baggage which he requires for which the modern car itself provides no carrying space, owing to the very low seats, now in use, and the monopolization of the rear of the body, by the spare tire equipment. Judiciously used, the light trailer is an extremely handy and valuable motor car accessory, immensely increasing the all-around usefulness of the car to which it is applied but, like everything else, it should be used in a reasonable way and one should not try to "mope mountains" with it over rough, hilly roads and then wonder why his car suddenly requires repairs.

CARBURETOR JET MAY BE OBSTRUCTED

H. A. M. writes: For the last few days my engine has failed to run properly with anywhere near full gas, spitting and missing when I open the throttle. When I close the strangler it stops doing this, but then runs "loggy" and will not speed up. Where should I look for the trouble?

Answer: It looks as if your engine were not getting gasoline enough to produce a sufficiently rich mixture and we suspect that the spraying jet of your carburetor is partially obstructed with dirt. When this is the case, enough gasoline often passes the



obstruction to permit low throttle operation, but not enough for full throttle operation. When you close the strangler, you increase the suction upon the jet so that enough and probably too much gasoline is delivered, but you also cut off the air supply, which causes the "loggy" action. We don't know what carburetor you have but its gasoline passages should be cleaned out, if possible without losing the adjustment. Of course, the trouble may be that the auxiliary air-valve holds open, which would produce a similar result.

OIL-LESS BUSHINGS FOR SPRING BOLTS

H. Y. writes: I am overhauling my car and find that the spring bolts are so badly worn in the spring-eyes that I shall have to make replacements. My mechanic advises me to put in oil-less bushings instead of bronze ones, claiming that they wear well and do away with grease cups and the attendant bother. What do you advise?

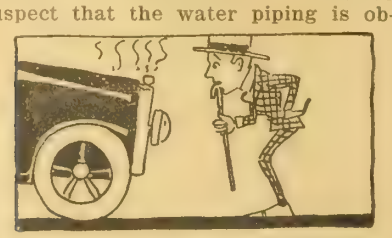
Answer: There is a tendency toward the adoption of non-metallic bushings in spring-eyes and good re-

sults are being obtained. If you use suitable bushings and the work is properly done, you will probably obtain satisfactory service, but this practice is of a somewhat experimental nature thus far. Impregnated wood, compressed asbestos, vulcanized fibre and other materials are used. Many materials capable of holding their shape and free from the tendency to abrade the metal of the pins seem available for this purpose.

ENGINE OVERHEATS

D. S. C. asks: What do you suppose makes my engine get so hot and steam come out of the radiator cap, when the car is stopped? I have washed out the radiator with soda and put on a new fan-belt, but the trouble is still there. The pump appears to be working all right.

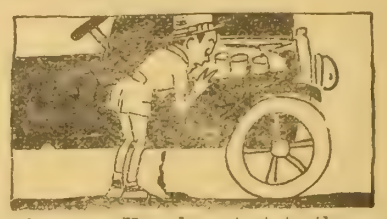
Answer: If there is really anything wrong in the cooling system and the trouble does not arise from using a badly proportioned mixture, from faulty valve or spark timing, inadequate piston lubrication or abnormal friction somewhere about the car we suspect that the water piping is ob-



structed. If the engine becomes hot while the radiator is comparatively cool, this is probably the cause. The linings of rubber hose connections sometimes become loose and partly obstruct the circulation and sometimes the hose from the radiator to the pump becomes so flabby, that it sucks together and stops the flow. Watch this hose with the engine speeded up and if it tends to collapse replace it. If you disconnect the upper hose from the radiator, water should be thrown from this in a full sized stream for 10 to 20 feet when the engine is speeded up if everything is unobstructed. Sometimes the pump impeller breaks or becomes loose on its shaft. This test will determine whether it is working properly.

OVEROILING IN EIGHT CYLINDER ENGINE

L. S. writes: I am having the following lubrication trouble with my eight cylinder engine. Oil comes out of the muffler pipe connected with the hight hand cylinder block and the plugs of these cylinders foul. The other side is all right. My oil pressure gauge does not register, probably on account of something wrong with the oil pressure regualtor. I have taken out the pistons from the right hand block and find them and their rings in good shape. At least, there are no brown spots on them. What is the cause of this trouble?



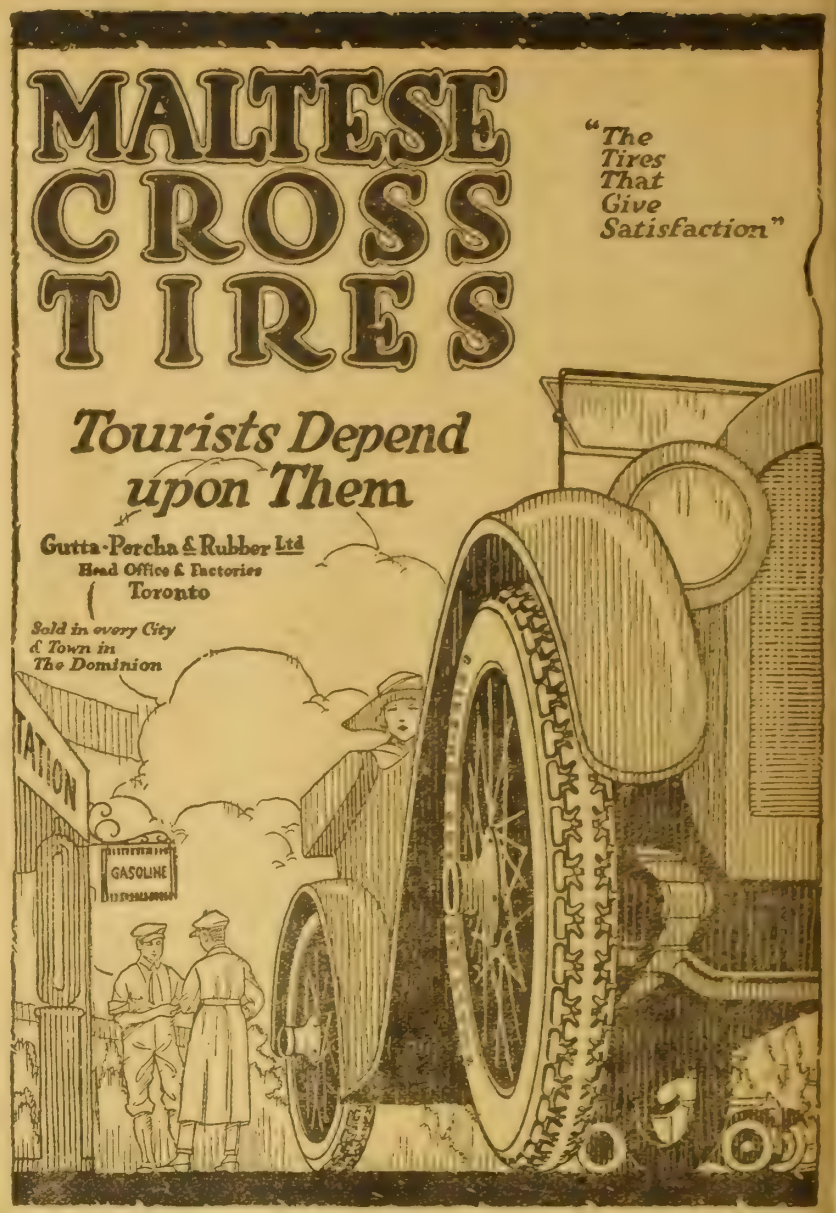
Answer: You do not state the make of this engine and thus we are in the dark as to the details of our lubricating system. There has been some trouble experienced in equalizing the lubrication received by the two sets of cylinders in this type of V engine, there being a tendency for the cylinders of the right block to become over lubricated, in case there is an excess of oil thrown about in the crank case. At high speed, this is quite likely to occur unless the pressure of oil is kept down to a reasonable volue. May it not be possible that there is something wrong with the pressure relief valve, which permits too much oil to be supplied when the engine is running fast? If you find nothing wrong with the teroiling system, it may be that the piston rings on the overoiled pistons do not fit so well as they appear to, but if overoiling is general on the right hand cylinders we should infer that there was something out of order about the lubricating arrangements themselves.

FORD TRANSMISSION LACKS NEUTRAL POSITION

J. P. writes: I have much trouble in cranking the engine of my 1916 Ford, as tehre seems to be no neutral position in which the engine is free to turn. Also, it will not coast freely. Is there some bearing worn out that allows the gears to drag or doesn't the high-gear disengage properly?

Answer: We can hardly do better than quote the Ford Manual in this connection—"it indicates that the clutch-lever screw which bears on the clutch-lever cam has worn and requires an extra turn to hold the clutch in neutral position. When the clutch is released by pulling back the hand

lever, the pedal should move forward a distance of one and three-quarter inches in passing from high speed to neutral. Also be sure the slow speed



band does not bind, on account of being too tight. Don't use a too heavy grade of oil in cold weather, as it will have tendency to congeal between the clutch discs and prevent proper action." Assuming that nothing is worn out, we believe that attention to the high-speed clutch adjustment will remedy your trouble.

THE COLLAR

The collar should be just large enough to permit a man's hand to pass inside the collar between the lower end of the collar and the neck or breast of the horse. If the collar is too loose it will cause friction; if too tight it will choke the horse, and cause sore withers. Test the fitting of the collar by lifting up the horse's head.

The hames should fit the collar; if too long, they will probably be buckled too tight at the top, and in this way the collar will be made to pinch the horse at the top. Sores thus produced begin by a pimple or very small boil, often overlooked because the mane covers it.

Examine your horse continually, and if there is any sore spot, adjust the collar so that it will not touch that spot. If the skin is merely wrinkled, bathe it with witchhazel or diluted vinegar. If the skin is broken, bathe it with clean water, containing a little salt.

If the collar "rides up," it can be kept down by a martingale running to the girth, or by an extra girth runnin gfrom trace to trace, back of the forlegs.

The best collar for a mature horse, whose weight does not vary much throughout the year, is the leather collar. But for most horses, the best collar is one stuffed with hair, and covered with ticking. With this collar, if the horse's shoulder becomes sore at any point, the lining of the collar can easily be ripped, and the hair removed or pushed aside at that point, so that no pressure will come on the sore place.

Collar pads are much used, but they quickly become dirty, cannot easily be cleaned, and thus cause many sores. Still, a pad that makes the collar fit is better than an ill-fitting collar without a pad.

By all means, clean the inside of the collar every night. If you wait until the next morning, you are likely to forget it. Of course you will clean the horse's shoulders as soon as the collar is removed. The salt sweat drying on the skin is what does the mischief.

BELTS AND PULLEYS

Pulleys carrying belts which are not to be shifted should be crowned, that is, the centre should be higher than the edges, the relief varying from one-sixteenth inch in small to one-eighth inch in large pulleys. This is because, owing to the higher speed of the centre, the belt tends to climb. Where pulleys are to be shifted the driving pulley should always be flat, the belt being maintained in position by the tight and loose pulleys of the driven members. If this is not done the belt will take a position on the crown of the wide pulley and ride partly on the tight and partly on the loose pulley.

There is absolutely no economy in feeding less than the fowls and chicks (especially the chicks) will eat.

Cows vary in their cost of keep as in their ability to use economically the feed.

MARKETS.

CHARLOTTETOWN

Beef, carcass, ox, 22c to 23c; cow, 18c to 20c.
Veal, carcass, 14c to 16c.
Hogs, 19c to 20c live weight; very few offering.
Lamb, 30c lb., (carcass).
Mutton, carcass, 22c.
Beef Hides, 34c.
Sheep Skins, stots, 60c.
Calf Skins, 74c lb.
Potatoes, 80c to $1.00 per bushel; very few available.
Carrots, none.
Turnips, none.
Parsnips, none.
Oats, 85c to 90c per bushel.
Cornmeal, $4.50 per bag.
Bran, $2.40 to $2.50 per bag.
Oatmeal, $6.00 to $6.50 per bag.
Middlings, $2.50 to $2.60 per bag.
Cotton Seed Meal, none.
Oil Cake, $3.75 to $4.25 per bag.
Buckwheat, none.
Ontario Flour, $12.00 to $12.15, wood.
Manitoba Flour, $12.00 to $12.50, wood.
Chickens, none.
Fowl, none.
Turkeys, none.
Geese, none.
Butter, Creamery, 50c to 55c.
Butter, Dairy, 40c to 45c.
Cheese, 28c to 29c; market unsettled and lower prices likely to prevail.
Wool, 70c to 72c.
Eggs, 42c to 43c.
Hay, Pressed, $23.00 to $25.00 per ton.
Straw, Pressed, $11.00 to $14.00 per ton.

THE LOCAL GRAIN MARKET

Montreal, Aug. 4.—On reports of showers in some of the corn belt and more liberal selling a weaker feeling developed in the market for future options and prices closed at a decline of 1⅜c to 2½c per bushel, but on the other hand the July future was strong and scored another advance of 1⅜c. Oats were easier and sold ⅜c to ⅝c lower, while rye declined ¾c to 1c and barley was very strong, closing with a net gain for the day of 2½c to 3¾c per bushel. The undertone to the Winnipeg market for oats continues strong and with good buying advanced ⅜c to ¾c, and barley 2⅜c to 2⅞c, while flax was weaker and declined 5c.

A firm feeling prevailed in the local market today for cash grain, and prices generally were maintained. There was some demand for oats from local buyers and sales of a few round lots of No. 3 Canadian western, extra No. 1 feed and No. 1 feed were made ex-water, and a few odd cars ex-store, but the volume of business on the whole was small and the market is quiet with No. 3 Canadian western and extra No. 1 feed quoted at $1.03½ per bushel ex-store, and ex-water at $1.02½. A few odd cars of barley changed hands for shipment from Ontario points, and No. 3 on spot was quoted at $1.53 per bushel ex-store.

THE LOCAL FLOUR MARKET

Montreal, Aug. 4.—There was no important change in the condition of the local flour situation today, but there may be some developments of importance in the near future. The demand from local and country buyers for Government standard spring wheat grade continues good and a fairly active business is passing for prompt and nearby delivery, wtih sales of car lots for shipment to country points at $11 per barrel in jute bags, ex-track, Montreal freights, and to city bakers at $11, ex-track, or at $11.10 delivered, while broken lots sold to city bakers at $11.10, ex-track, and to grocers and other dealers at $11.20, ex-track, all less 10c per barrel for spot cash. A very firm feeling prevails in the market for old crop winter wheat flour owing to the fact that stocks in first hands on spot are about exhausted. There were some enquiry today for small lots and a few sales were made at $11.40 to $11.50 per barrel in new cotton bags, and at $11.20 to $11.30 in second-hand jute bags, ex-store. New crop wheat flour is commencing to be offered by Ontario millers a little more freely and some business has been done in car lots for prompt shipment from the mills. The quality of the flour for the season of the year is reported to be very good. There is no change in the market for white corn flour, prices being maintained with a steady demand for small lots at $10.60 to $10.70 per barrel in jute bags, delivered, and re flour is quiet at $8.50, to $9.

MILLFEED AND ROLLED OATS

Montreal, Aug. 4.—The condition of the market for all lines of foodstuffs is strong and the prospects at present are for higher prices in the near future owing to the fact that supplies are none too large for which there is a good steady demand from all sources and a fairly active trade is reported. Sales of broken lots of bran in mixed cars were made at $45, shorts at $48, pure barley meal at $68, mixed grain moullie at $66, mixed moullie at $58, dairy feed at $50, and oat middlings at $47 per ton, including bags, delivered. There was no further change in the market for rolled oats, but prices rule very firm at the recent advance noted with a small trade passing in broken lots of standard grades at $5.25 per bag of 90 lbs., while Golden cornmeal was quoted at $5.50 per bag, delivered to the trade.

THE BALED HAY MARKET

Montreal, Aug. 4.—According to private advices received here from the United States today the tone of the market is stronger for some grades and prices have advanced $2 per ton. This had a tendency to create a better edmand here today for car lots and especially so for clover mixed hay for shipment to the above market and purchases of quite a few cars were made on spot and in the country. The domestic trade was quiet, but the tone of the market was steady with car lots of good No. 2 Timothy hay quoted at $28, No. 3 Timothy hay at $25, and clover and clover mixed at $20 to $22 per ton, ex-track.

THE PROVISION MARKET

Montreal, Aug. 4.—According to advices from Toronto on Tuesday an easier feeling had developed in live hog market since the close of last week and the prices quoted showed a decline of 25c per 100 lbs., with sales at $24.50 per 100 lbs. weighed off cars and at $24.25 fed and watered, while the f.o.b. price was 50c lower than last Thursday at $23.24. In spite of the above and the fairly liberal supplies coming forward to this market, the feeling has continued strong, and prices today scored an advance of 50c per 100 lbs. At the higher level there was a good demand from packers for all offerings, and an active trade was done. The quality of the stock was better owing to the fact that percentage of rough, heavy, sows and stags was smaller, and sales of selected lots were made at $24 to $24.50 per 100 lbs. weighed off cars. On account of the above the undertone to the market for dressed hogs was also stronger, and prices were marked up 50c per 100 lbs. The demand continues to be somewhat limited owing to the small consumption of pork in the hot weather and trade was quiet, with sales of odd small lots of city abattoir freshkilled stock in a jobbing way at $32.50 to $33 per 100 lbs.

There were no new developments in the market for smoked or cooked meats, prices for all lines being firmly maintained in sympathy with the strength in the market for hogs, and under a continued good demand for supplies for domestic consumption. The trade in a wholesale jobbing way was active, and sales of 8 to 10-lb. hame were made at 45c to 46c per lb., 12 to 15 lbs., at 43c to 44c, heavy weights at 41c to 42c, cottage hams at 42c, picnic hams at 33c to 35c, cooked hams at 65c and cooked shoulders at 52c, breakfast bacon at 47c to 48c, special brands at 54c to 56c, Windsor selected bacon at 50c to 51c, and Windsor boneless bacon at 55c to 56c.

The tone of the market for lard is strong, but no actual change in prices has been announced as yet. The demand for supplies for domestic account continues good, and an active trade was done in a jobbing way, with sales of Canadian pure leaf grades at 38¾c per lb. in 20-lb. wood pails, and at 30½c to 40c in 1-lb. blocks, while American compound lard is selling at 27½c in 20-lb. wood pails, shortening at 32c to 34c in 1-lb. blocks, and at 31c to 32c in 20-lb. wood pails.

The receipts of provisions today were 50 packages lard, 1,680 boxes hams and bacon, and 1,273 packages tinned meats.

FOREIGN GRAIN ADVICES

Liverpool, Aug. 4.—The situation in the United Kingdom remains very firm. Offerings of corn have been extremely light and even cornmeal is now being put forward in only limited quantities. Supplies of the latter have dwindled rapidly and are now of rather moderate proportions. Prices for cornmeal are advancing with values now quoted at 22⅝ pounds per English ton. We continue to receive complaints regarding the Italian crop which is suffering from the lack of moisture in sections. On the other hand, weather in the Argentine has been exceedingly favorable during the past week and the movement of corn from the interior is increasing in volume with a consequent enlargement in holdings. It is generally conceeded that the heavy precipitation experienced during and immediately after harvest caused such deterioration to the new corn crop in the southern grower, but it may be pointed out that the Argentine has an enormous surplus, and even allowing for a loss of about one hundred million bushels, or around one-half of the out turn, this country still holds liberal quantities of corn sufficient in fact to satisfy any likely European requirements, during the season.

Oats—There is a good enquiry for foreign oats in the United Kingdom at the maximum price of 59s for the American and 61s for the Canadian per quarter. These maximum prices are now under a foreign parity so that export business with both America and Canada has practically subsided. Reports of continental crops make France's prospects poor but those of Germany fair to good and in this connection it may be pointed out that Germany annually grows a large percentage of the oats in Europe.

STOCK NOTES

Orchard Hill Farm, Brown's Flats, N. B., have recently imported from the UnitUed States the pure bred Jersey bull "Pogis' Golden Port", an animal of excellent breeding and a nice individual. He is a grandson of the great Pogis 99th of Hood Farm, and has two crosses to "Fort Hill Farm Chief", the sire of Sophie 19th of Hood Farm, the champion long distance cow of the world with a record of 6600 lbs. butter in 7 years. His sire's dam has a record of merit test of 540 lbs. in 351 days and is a half sister of the richest official butter fat test cow in the world. His maternal granddam has an official record of 556 lbs. and is by Flying Fox's Victor, a sire of both high class show stock and great producers. He also has a half sister, from same dam, with record of 422 lbs. at 2 years. As this young bull carries much the same line of blood as the imported Grandiflora's Kathleen, now owned by Orchard Hill Farm, good results are expected from this mating. Orchard Hill Farm would extend the service of this bull to anyone wishing the service of a really high class animal.

ORGANIC MATTER

Ordinarily one thinks of organic matter in the soil merely in terms of fertility or plant food. To plow under a cover crop represents to one so much organic matter which will undergo decay and in so doing release certain soil elements of value to growing crops. However, the physical qualities of organic matter are of an importance scarcely if any less than the purely chemical or food providing resources which centre in it. Organic matter tends to make a soil dark in color, consequently it absorbs more heat and warms up sooner in spring. This in turn results in more rapid growth of the bacterial organisms which ply their trade in the upper layer of the soil and which are so necessary in the development of plant growth. In addition to this, organic matter makes a soil more porous and consequently increases its water-holding capacity. As a result it becomes more resistant to drought. All told, the purely physical influences which accrue as the result of adding organic matter to the soil are of far greater importance than many people would suppose.

WHITE-WASH RECIPE

A whitewash recipe which is popular for use around the farm consists in slaking a half bushel of lime in boiling water, keeping it covered during the slaking process. The lime is then strained and one peck of salt dissolved in warm water is added. Three pounds of ground rice are boiled with water to a thin paste; while half a pound of powdered Spanish whiting and one pound of clear glue are dissolved in water and then all these materials are thoroughly mixed together and allowed to stand for several days. This wash should be prepared in a kettle or portable furnace as, for best results, it should be applied as hot as possible with paint or white-wash brushes. The washes which contain milk, flour or glue should not be used in damp interiors because of the tendency of the organic matter to decompose. For such work it is preferable to prepare a whitewash according to some formula which does not include these ingredients. In all cases, whitewash is best applied with a broad, flat brush, the liquid being spread lightly over the surface which is to be painted. No attempt should be made to brush in the whitewash, as is done with oil paint.

FLY POISONS

The following are very convenient and effective fly poisons: Bicromate of Potash, one dram in two ounces of water. Add a little sugar. This mixture is not dangerous to human life. Another poison is one teaspoonful of formalin in ¼ pint of water. This must be kept away from children and house pets. To quickly clear a room where there are many flies, burn pyrethrum powder and sweep up the flies.

A PLACE FOR SKIM-MILK

In tests made in the Missouri station it was found that at the end of the first three weeks 100 chicks with skim-milk as the ration weighed 21.4 pounds, at a cost of 2.76 pounds of feed per pound of gain, the beef-scrap chicks weighed 15.1 pounds at a cost of 5.54 pounds of feed per pound of gain, and the no-milk-or-meat chicks weighed 9.86 pounds at a cost of 15.1 pounds of feed per piund of gain. The mortality in the lots was 13, 22 and 34 per cent. respectively.

SPRAY PINK AND GREEN POTATO APHIDS

(Continued from page 767)

kerosene emulsion and the one recommended on our spray calendar calls for one-half pound of soap and two gallons of kerosene to make thirty gallons. In this formula the soap seemed to be insuffiicient for the kerosene, so we increased the proportions somewhat. We also doubled the amounts of soap and kerosene but instead of mixing sixty gallons, diluted it less, to make fifty gallons, the right quantity to fill the spray barrel. Laundry soap was purchased by the box at wholesale prices, and the amounts of materials used were as follows:

Kerosene .....4 gallons
Laundry soap (about 30 oz) 3 cakes
Hot water .....2 gallons

After churning, dilute to make fifty gallons. The soap was shaved into thin slices with a tool for shredding cabbages, and was dissolved in water on a stove set up in the field for this purpose. It was then mixed with the kerosene and churned back and forth through a small tube under pressure by means of a bucket pump with the hose directed back into the liquid, after which it was transferred into the pump barrel and sprayed upon the plants with hand-power barrel pump with spray rods bent at an angle of forty-five degrees near the nozzles.

This emulsion was effective, and all aphids hit by the spray were killed. A part of one field was sprayed with nicotine solution and soap for comparison. Some of the men who applied the mixture thought that slight injury was caused by the kerosene emulsion, but the same thing could be deetected on some of the plants before they were sprayed. The variety was "Gold Coin," and there were many mosaic plants in the fild; the tissues break down and the leaves turn brown earlier on these plants and this is probably the explanation of the injury rather than the spray."

That there may be under some circumstances an opportunity to harvest a crop even during bad aphid years is indicated by the following statement from the Seventeenth Report of the State Entomologist of Connecticut for the year 1917:

"Mr. A. N. Farham, of New Haven, raised one of the best crops of potatoes in 1917 that he has ever grown. He planted early varieties as soon as the ground could be worked and matured the crop before the aphids came. One field at the Station farm gave a fair yield, but this was an early variety planted late, and was not attacked by aphids.

Although the pink and green aphid is treated in this account as relating to the potato crop alone, this species is during the summer months, what is tremed a "general feeder," being capable of developing the summer generations upon a large number of plants representing so far as yet ascertained ten or more widely separated botanic families. The fact that potatoes, which appear to be their favorite summer food, are grown over extended areas gives them an unlimited opportunity to spread when conditions in general are favorable.

Besides the pink and green aphid several other species of plantlice are known to infest potato, none of which have yet a record to equal the insect under consideration, although the "spincah aphid" (Rhopalosiphum persicae Sunzer) was present in varying numbers throughout the entire district infested by the larger pink and green aphid during the seasons of 1917 and 1918 and doubtless was a contributing factor to the potato disaster which extended half way across the continent.

Clean to handle. Sold by all Druggists, Grocers and General Stores.

DEFECTIVE CHIMNEYS DANGER TO HOME

Too much emphasis cannot be laid on the need for taking every precaution against the danger of fire in rural communities. In cities and towns, which are provided with proper fire appliances. many fires are arrested without any serious loss, but in rural districts where there are no organized fire fighting agencies, a fire usually amounts to a total loss; hence the need of using all possible means of prevention.

Common Cause of Fires

A summary of the various causes of fire, as given by fire cniefs, and other such authorities, reveals the fact that fires attributable to defective chimneys annually amount to from 10 to 26 per cent. of the total number, while in winter the proportion has reached as high as 50 per cent. Consequently it is up to farmers to give more attention to making the construction of chimneys as nearly fireproof as possible. tI is a well known fact that the ordinary brick and mortar chimney, as usually constructed, is always more or less of a source of danger. The constant heat from the fire, in time, causes the mortar to become so dry that it falls out of place leaving holes in the chimney. Such a condition may go unnoticed for a long time, and remain a constant source of menace.

Proper Chimney Construction

In constructing chimneys in buildings made of combustible material, the chimney should be built straight up from the ground and not placed on a bracket, as is often the case, and should extend 2 feet or more above the peak when the chimney is in the centre of the roof and 3 feet or more above the surface when on a flat or slanting roof. For proper draft, the minimum-sized opening for the flue should not be less than 64 square inches, while the walls should be at leats 8 inches thick. At the base of each flue a clean-out door should be provided, if possible. Whatever the material used in construction, it should be of good quality and laid in cement. Flue holes should never be filled with any inflammable material, but should be covered over in a secure manner with a metal flue stop.

The joists used to support the floors through which the chimney passes should not have their ends supported in brick, as the chimney may settle, leaving at these points, cracks through which fire may creep to the joists. Moreover no woodwork should come in contact with the chimney.

Fireproof Flue Linings

To overcome the fire hazard in brick chimneys, nothing is more effective than the scheme of providing some good fireproof flue lining. Such lining may be either fire clay or terra-cotta tile, and no difficulty will be experienced in its use. If fire clay is used instead of terra-cotta tile, the results will be similar if the size of the flue is not thereby cut down. The lining serves as a fire preventive, and in the case of terra-cotta tile gives a flue of uniform dimensions. The ordinary brick chimney will not do this. With lining the flue presents a smooth surface, which leaves no place for soot to gather, thus eliminating to a great extent the possibility of chimney fires. The cost of such a lining for an ordinary two-story residence would be nominal, and the lining should prove a cheap and effective means of fire protection. Fire brick might also be used in place of the fire clay or terra-cotta tile, with equally good results, but at a greater cost.

When the home is already equipped with an ordinary unlined brick chimney, the danger of fire will be very much lessened if it is given a close inspection at frequent intervals. If any breaks or cracks are noticed they should be at once repaired. Another important item is to see that the chimney gets an occasional thorough cleaning. This may be done quite readily with any sort of an improvised scrapping device, as for instance a pair of old automobile chains tied on the end of a rope.

CONCRETE TILE FOR DRAINAGE

During the past few years the manufacture of cement drain tile has developed into a big industry. On account of the fact that it is an easy manufacturing enterprise to start, a good many inerperienced men began the manufacture of concrete tile. As a result there were in the beginning many inferior tile made. Careful investigation shows that wherever concrete tile have failed, it has been for one or more of the following reasons:

Improper seasoning of the tile.

The use of too lean a miyture of concrete.

The use of too dry a mixture.

Attempting to use the tile before they have sufficiently hardened in order to have gained the strength necessary to withstand the action of soil water upon the concrete.

The greatest difficulty which was experienced in the use of concrete tile was in alkali soils. However, by proper manufacturing methods, concrete tile are just as serviceable as clay tile. In order to prevent failures the American society for testing materials has adopted certain standards which ought to be followed if the best results are to be secured. Briefly the most important points are:

Clean and well-graded sand from very fine particles to those which will pass a ¼-inch mesh screen for all farm drain tile of less than 10 inches in diameter.

Proper proportioning and mixing of materials, using a mixture of not more than one part cement to three parts sand.

The machine that is used should be one that will enable the operator to properly pack the material so that the minimum density will be obtained.

The thickness of the tile walls should be uniform.

Perhaps the method of curing is the most important point. This can be accomplished by one of two methods: Either what is known as steam seasoning or water seasoning. In some cases a combination of both methods is used. If steam curing process is used, this method briefly stated is accomplished by placing the tile in eepecially arranged steam chambers. The steam chamber must be tight enough to prevent the circulation of air and must be so arranged that the steam entering the chamber does not come in contact with the green tile.

If the water hardening method is to be used, the tile must be kept some place where evaporation will not take place rapidly and no water applied until they have hardened sufficiently so that the application of water will not injure the surface of the tile. They should be kept wet by sprinkling for not less than seven days. The temperature ought not to be lower than 70 degrees. They should be stored in the yard for not less than 14 days after being removed from the curing room before being used.

There are, of course, many more details than those given which one would have to know before starting the manufacture of concrete tile. Anyone who is considering the purchase

of tile will see that concrete tile in order to be satisfactory to use in a tile drainage system must be well made. Concrete tile have been in use for a sufficient length of time, so that there is no question regarding their practicability.

HINTS FOR TRACTOR OPERATORS

Because of the farm labor shortage and because of the advance in price of man and horse labor over that of gasoline, there will be a greater demand for tractors on the farm this year than ever before. n view of the fact, it behooves us to repair and keep in sufficient use not only those machines that are in use, but also those partially disabled.

Repair work on the tractor must be done early, as repair parts, this year will be more difficult to obtain, due to congestion of traffic and the inevitable war shortage of materials.

"Cleanliness is next to Godliness," and is very essential in the successful operation of a tractor. Old grease serves merely to collect and hold dust and this mixture of dust and grease is then a grinding agent instead of a lubricant. A few gallons of kerosene will take off all the dirt and grease and make the tractor look like new. When clean, it is much easier to perfect adjustments than when the parts are clogged and hidden from view.

Since most tractors have exposed gears, the question arises as to how these gears can be lubricated and still not collect dirt. Some companies answer this by saying that you shrould not lubricate the gear where it is exposed to dirt. In this case they depend on hard faced gear teeth and think that a clean, dry gear will wear longer than a dirty one even though the latter is greased. It is possible to use a lubricant on these exposed gears which is so dry that it will not collect dust. Such a mixture is made by moistening equal parts of flake graphite and powdered rosin with gasoline and smearing this on the gear teeth. The gasoline evaporates, leaving the rosin to hold the graphite in place. This, of course, applies only to drive gears.

The lubricating system should be examined to make sure that it is working correctly. Over 90 per cent. of tractor troubles are due to improver lubrication. Here, again, cleanliness is absolutely essential. Unless the machine is in such bad shape that it needs overhauling completely, kerosene poured into the cylinders will soften carbon deposits, cut the gummy oil residue and loosen gummed piston rings. When the cylinders have been drained, the crank case must also be cleaned. Drain the old oil from the crank case and fill it with kerosene. Turn the engine over a few times to clean the case, and then drain out the kerosene as before. Carefully examine all bearings to see that they are tight and then refill the crank case with new oil.

See that there is proper clearance between the valve push rods and the valve stems when the engine is turned over. It should equal the thickness of a thin postal card.

Keep a supply of spark plugs on hand, also a few good tools. Good tools, properly cared for, will save a lot of time and money when the spring work begins.—E. M. Mervine.

TYPE ESSENTIAL IN BREEDING

There has been more or less discussion on the question of type during the last few years, some breeders taking the position that it was the record that the cow made rather than the type of individual that fixed the selling price, and that all the breeders could consider was the price and not the characteristics of the animal as to type. I do not agree with that position, nor do I believe that the Holstein-Friesian Association can afford to. I am thoroughly convinied that type is one of the most important principles that must be adhered to. I am satisfied that 80 per cent. of all the high record cows are reasonably true to type, proving beyond all peradventure that type and high production can be attained. No breeder should presume to use a sire whose ogspring has sloping rumps and bad udder, no matter what the record of his dam may have been.

The fact that animals do not breed true to type is evidence itself that we have neglected type to a greater or less extent in the past.

I believe, in awarding premiums, that large production should stand for a certain number of points. On the other hand, I do not believe that premiums should be awarded at all to an animal that is not a credit to the breed, regardless of whether or not there was any competition in the ring. I have visited fairs and seen shows of live stock, not only those of the Holstein-Friesian breed, but of others, where there was absolutely no excuse for giving them a premium; where they were not a credit to the breed, but rather a discredit, but because of no competition they were awarded prizes. This, it seems to me, is obsolutely wrong, and I believe that in awarding premiums at fairs, we should have some rule laid down clearly definng the requisites necessary to entitle animals to prize money.

I think the breeders, generally, realize that we have not been particular enough about type; they realize that there are a great many herd sires in service that ought not to be considered or tolerated. They are there simply because of the records of the dams. In some instances the calves you get of the animal are creditable, and in such instances they do no harm, only as it may acect future generations of the breed.

I think also, that those breeders who think records alone fix the price are wrong. I have seen men put 30-lb. cows in a sale ring for less than half the price of a typey cow with a very much less record, showing that type is considered in the auction ring as helping to fix the value of the animals, and I believe it would be a very hard matter to sell a real sloping herd sire at any price, at the present time, regardless of the record of the dam.

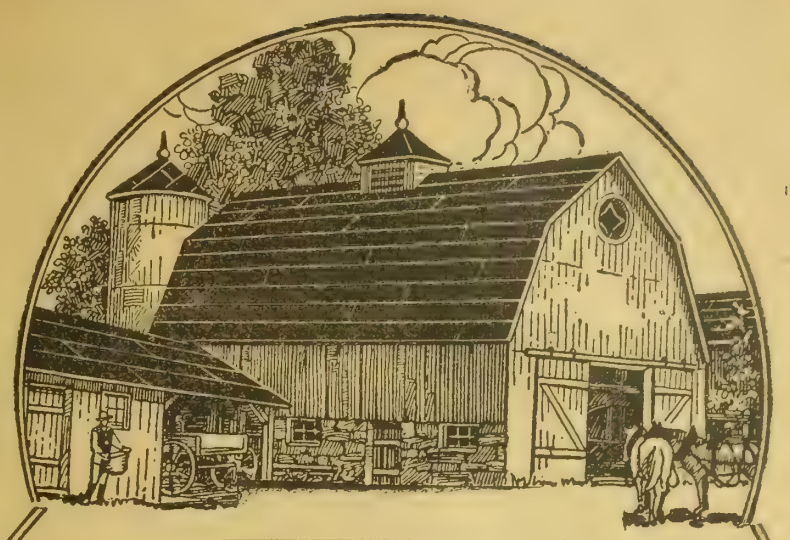
HON. D. D. AITKEN, President American Holstein-Friesian Assn.

DOES SOUR CREAM GIVE HIGHER TEST?

This question is often asked: "Does cream test higher when it is sour than when it is sweet?" Many have been led to believe that by holding their cream on the farm until it was real sour they would be given a higher test. This would be possible under one condition and that is, if a can of cream were allowed to stand for a long time at a regular high temperature there would be enough moisture evaporate to increase the percentage of fat slightly but this would be very slight and in that time the cream would no longer be fit for human consumption. Even then the extra percentage of fat would only make up for the amount of moisture which has evaporated.

For instance, if there were 80 pounds of sweet cream testing 30 per cent. butter fat, in this amount there would be just 24 pounds of butter fat Supposing this were allowed to stand until five pounds of moisture had evaporated this would then leave 75 pounds of cream testing 32 per cent. fat. It would also yield 24 pounds of butter fat and it is needless to say that the butter made from this 75 pounds of so-called cream would not be fit to eat.

It may be true that in some cases a higher test has been reported when the cream was sour, especially in thin cream. If a can of cream has been allowed to stand for any length of time and becomes sour the milk solids would settle and become very sour and firm. This makes it almost impossible to get the can of cream thoroughly mixed, therefore, the sample which is taken will not represent the contents of the can it is taken from as there would be practically no fat in the milk solids which are left unmixed. Many have, therefore, been led to believe that cream would really test more when sour than when sweet. If a higher test is given it is not accurate. W. H. UNDERWOOD.



Barrett's
EVERLASTIC
"RUBBER"
ROOFING

You can see the quality of Barrett's Everlastic "Rubber" Roofing as soon as you open the roll.

The best of materials, the utmost skill possible in manufacture, and the experience of over sixty years in making high-grade roofings goes into every roll.

Thousands of rolls of Barrett's Everlastic Roofing have been used by the Canadian and U. S. Governments, the leading railroads, and the largest contractors in the country. Dollar for dollar, it is the best "rubber" value obtainable today.

Don't waste your money on poor roofing that will need to be renewed in a short while. It will pay you better to insist on Barrett's Everlastic and see that you get it. The name Barrett is your guarantee against disappointment. You will find it on every roll of the genuine Barrett Roofings.

HARD LUMP ON BULL'S LOWER JAW

I have a three-year-old Holstein bull that has a lump on the lower jaw. It is quite hard, and two months ago bothered him quit ea bit when eating, but lately not so much. A. C.

If the lump has appeared as a result of an accident or blow on the edge of the jaw-bone, rub it daily with tincture of iodine, but first clip the hair off the lump.

If the lump arises from the lumpjaw disease, then medicinal treatment consists in giving the affected animal one drachm of iodide of potassium three times a day in a soft mash, till the effects of the drug was visible in the production of slavering at the mouth, tears in the eyes and loss of appetite. Then stop for a week and repeat the drug treatment. A couple of months or so of this treatment will usually cure a case that has not been allowed to run too far. Keep the bull isolated from the rest of your herd until cured, as it is somewhat contagious.

GETTING AT COST OF PRODUCING MILK

"It cost us $1.08 per hundred lbs. labor not included, to produce milk on the Macdonald College farm for the seven months just past," said L. C. McOuat, B.S.A., of Masdonald College to a staff representative of the Ottawa Farm Journal a few days ago. Mr. McOuat went on to explain how the cows were fed. and pointed out that no special effort had been made to make a record for cheap production. An individual feed cost was kept of every cow, as is always customary, and against this was the milk yield. There were altogether 45 cows in the test, and they were in all stages of lactation, many of them freshening throughout the winter and others almost dry. The labor of caring for the herd was not included. Asked as to what constituted the main rations, Mr. McOuat replied that for roughages, clover hay, corn ensilage and a few roots were principally used. while the meal ration was made up of distillers' grain, wheat bran, gluten and oilcake in various proportions. Naturally the rations varied from time to time, and also with the individual cows, but generall speaking that was the usual programme of feeding.

DISEASE SPREADERS

In the control of animal diseases the proper disposal of carcasses is important. Infectious and contagious diseases can be spread by leaving the bodies of dead animals where dogs, birds and other animals can get to them. The best methods of disposing of such carcases is to burn them until nothing but ashes remain. As this is often quite a task, especially where it is a large animal, the next method is burying under at least 5 feet of soil, covering the body with plenty of quicklime.

COSSAR STOCK FARM
Lower Gagetown, N. B.

Importers and breeders, Clydesdales, Dairy Shorthorns and Border Leicester Sheep

Orders now booked for EWE and RAM LAMBS for fall delivery, several extra good animals for sale out of Ewes clipping 10 to 12 lbs. and sired by an Imported Ram weighing about 400 lbs. with a clip of 18 lbs.

BREED LEICESTERS the Sheep with THE HEAVY FLEECE.

Auto Tires $17.50

Fine non-skid tire for small cars, size 30 x 3½, fully guaranteed for 3500 miles

The Maritime Farmer begs to announce a substantial reduction in the price of non-skid tires for small cars, Fords, Chevrolets, Maxwells, etc. They are FIRSTS, fully guaranteed and we will sell them to you, provided you are a paid-up subscriber to the Maritime Farmer for $17.50 f. o. b. Sussex. Plain tires for $16.25, fully guaranteed for above mileage. Tubes for same size tire $2.90. These goods are all A1 stock and are made by a well known tire house. Of course these prices are for spot cash with order. The Maritime Farmer was able to take advantage of the recent break in the market and its large buying capacity to get you the benefit of this substantial cut in price. IT'S THE BEST BUY IN CANADA Today. Write the Auto Department, Maritime Farmer, Sussex, N. B.

A VERY VALUABLE BOOK

The Veterinarian, by Charles J. Korinck, V. S., is a work on the afflictions of horses, cattle, sheep, swine, poultry, etc., which every farmer should have in his home. The story of how treatment can best be administered is told in simple every-day English that any person can understand. The methods suggested by Prof. Korinek are simple and easily followed. The book will cost you seventy-five cents, postage paid. It may be the means of saving you as many dollars in the near future. How many men are there who meet trouble by writing to the Maritime Farmer or some other paper for information which will be found in the Veterinarian? It is strongly bound in cloth, has serviceable illustrations and is well indexed. Seventy-five cents will bring it to you.

HOW TO MEND GRAIN SACKS

Grain sacks can be mended very nicely by using a crooked needle, and if you can not get a bent needle of your dealer, take a strong darning needle and hold the point in the fire a short time to draw the temper, then bend to suit. Get a light, smooth board 18 inches by 12 inches and round off the corners so it will slip in the sack easily. Turn the sack inside out, insert the board, then lay on your patch and sew around the edge of the patch, using the over stitch. Reverse the sack, insert the board as before, always keeping the board directly under where you are sewing, and over stitch around the edge of the hole, or for neatness, turn under and sew. Wrapping cord that comes around store goods makes good mending thread if waxed with beeswax.

Chester White Pigs for Sale

Book your orders now for Chester White Pigs from four weeks upward. Pairs furnished that are not akin.

W. A. ERB, SUSSEX, N. B.

ELMHURST STOCK FARM

Clydesdale Horses, Hereford Cattle, Leicester Sheep.

We are offering 4 Bulls fit for service, 9 to 12 mos. old. They are good thick, straight bulls fit to head a herd in any county. Prices moderate. We have Rams and Ewes for fall delivery. Write your wants, we can suit you in quality and prices.

William O'Brien & Sons, Windsor, N.S.

FOR SALE !

Several young bulls of serviceable age and youngsters. Well bred and good individuals. Prize winners at our recent show. Their dams won 1st, 2nd and 3rd in the ring of aged cows; also 1st and 2nd in the dairy test, 1st in heifer class and 1st in grade cow, competing against all breeds at our late show at Charlottetown, with an average fat of nearly 4 per cent. We will send photos of these young bulls and their dams to any prospective buyers. For quick sale we have priced them at from $50 to $125.

W. M. LEA,
"RIVERSIDE FARM," VICTORIA, P.E.I.

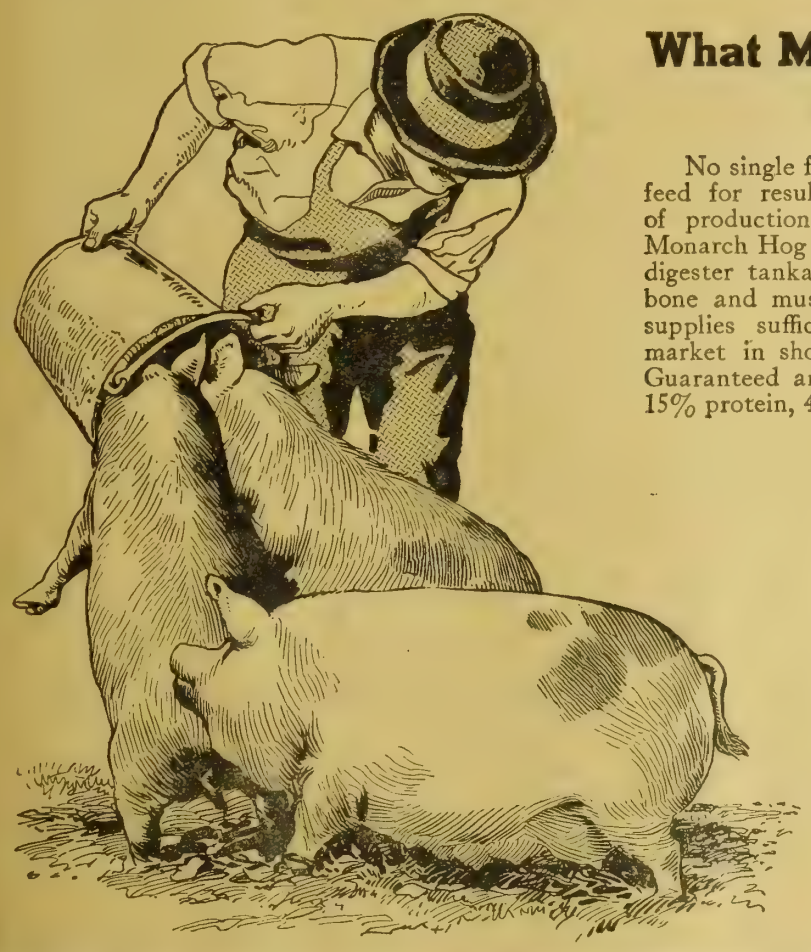
More Pork and More Profit

Heavier, Cheaper Hogs in Less Time

HOW to round your hogs into tip-top shape for an eager market at lowest cost—that is the problem Monarch Hog Feed is solving for farmers every day. Monarch Hog Feed is a properly balanced feed, supplying every requirement for sturdy hogs with stamina, energy, vigor and size; it has exactly the right proportion of protein and fat to finish your hogs in the shortest time.

Monarch Hog Feed

makes more pork and better pork; it shortens the hogs' stay on the farm and reduces cost of production; it gets hogs to market in best condition; in fact it solves the problem of economical feeding in these strenuous times of high-priced feeds—and there's money in good hogs nowadays. Improper feeding is one of the causes of soft bacon, declares Prof. G. E. Day in Ontario Agricultural College Bulletin No. 225. Monarch Hog Feed used along with the proper amount of roughage means good hard bacon that gets the best prices.



What Monarch Hog Feed is made of

No single feed can equal the properly mixed feed for results as to gain per day and cost of production. The principal ingredients of Monarch Hog Feed are shorts, corn products and digester tankage. This combination is rich in bone and muscle forming ingredients, and also supplies sufficient fat to bring your hogs to market in shortest time and in best condition. Guaranteed analysis of Monarch Hog Feed is 15% protein, 4% fat.

Monarch Dairy Feed

has guaranteed analysis of 20% protein and 4% fat. It is a properly mixed combination of Oil Cake Meal and Cotton-seed Meal with the bulky feeds, bran and corn meal. Though very rich, ensuring splendid results, it can be fed alone.

Sampson Feed

This general purposes feed is somewhat similar to Monarch Hog Feed, except that oil cake meal is used instead of digester tankage: it gives results for both cattle and hogs. Guaranteed analysis 10% protein and 4% fat.

Pigs "go for" Monarch just as they are doing in the picture. It is a palatable, easily digested feed. For profitable results it is the most dependable feed—and, remember, you can depend upon getting it, while mill feeds are often unobtainable.

Give it a trial. Order a ton from your dealer and note results. If your dealer does not handle Monarch feeds, send us his name and we will see that you are supplied.

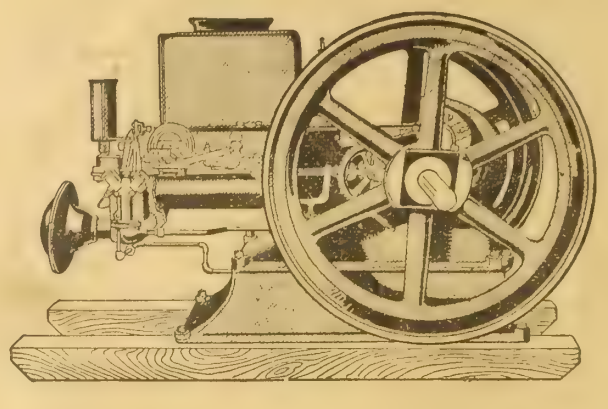
CURING THE BUTTNIG RAM

Rams that become butters are generaly tame ones. It is a good plan to have the ram tame, in order to feed him extra at tupping time, and be able to catch him to take him from one place to another at breeding time, or away from the ewes in the day time and back to them at night, which is good practice. But the taming of a ram can easily be done without teaching him the trick of butting. Never let a ram get in behind you that has the habit of butting, and keep the children away from them. A collar round the neck with a chain attached that will drag on the ground amongst the ram's feet is advocated as a reliable prevention of the habit. But for a positivey dangerous ram there is no reliable cure. If a person is attacked in the middle of a field, and has no means of gaining the shelter of a fence, he should lie flat on the ground and when the ram comes up to investigae the change of front you have made, as he will invariably do, catch hold of a foreleg and turn him on his back. He cannot get up when in this position, and by the end of ewenty minutes or so he will be so dazed and all the butting spirit will be out of him. From personal experience the writer has proved this method to be of practical value, when in a tight corner with a butting ram, but the preventative measure is to beware of fooling with them when taming them for practical purposes with the flock of ewes.

100% Efficiency with Kerosene



THE big thing to look out for when choosing a kerosene engine is this: Is it designed on true kerosene principles, or is it just adapted from machines built on gasoline principles? There is a world of difference. The *real* kerosene engine saves fuel and gives you maximum power. If you want 100% kerosene efficiency you will decide in favor of the

Renfrew Kerosene Engine

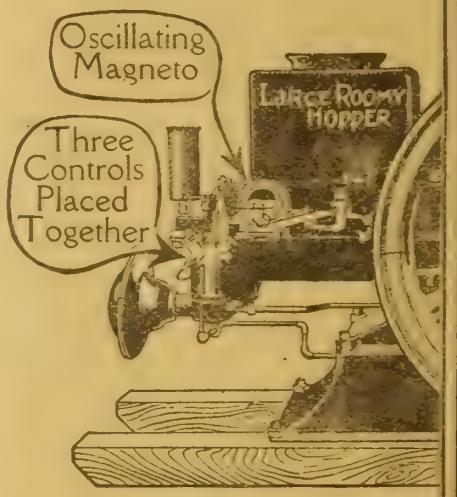
It is a *true* coal oil burning engine, designed precisely to get the last kick of power out of cheap coal oil. What a saving that means over gasoline at present prices we do not need to tell you.

Adapted engines simply cannot get the vaporized kerosene into the chamber warm enough. The Renfrew short manifold intake gets it to the right spot both *quickly* and in a *hot* condition. Thus it gets *full* power out of the fuel from both compression and explosion of the vapor.

In a real kerosene engine a big fat spark is indispensable. The Renfrew's oscillating magneto is designed to get that big spark at the right moment—and does it.

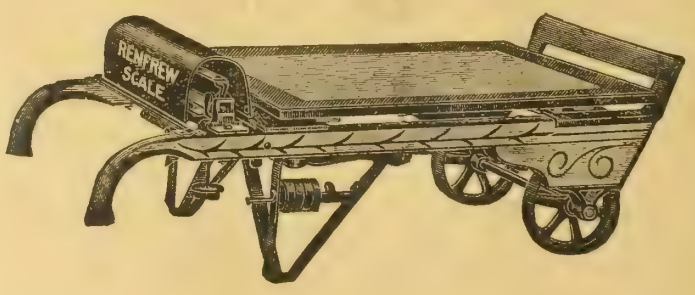
The special kerosene mixer, equipped with auxiliary air-valve, insures properly mixed charge for either light or heavy loads.

All these special kerosene features mean 100% service at the lower cost of kerosene over gasoline. That's the engine for *you*. Won't it pay you to get our illustrated booklet giving complete details? Write for it today.



You're Losing Enough to Pay for this Scale

A farmer often loses enough on one single sale of cattle on the hoof, or hogs, or sheep, to pay for a Renfrew Truck Scale. The only way to be on even terms with the shrewd, experienced cattle buyer is to weigh your live stock on the



Renfrew Truck Scale

This scale is Government tested. It has the Government Inspector's Certificate attached. No one can dispute its accuracy. Many farmers and stock raisers prefer to sell their animals dressed and make a still higher profit. Here again is the Renfrew Truck Scale a necessity. And after weighing you can truck the dressed hogs, beef, lamb, right to the wagon. Scores of other things can be weighed on this scale, too. Milk for the factory, grain, feed, groceries, etc. Weighs anything from 1 lb. to 2,000 lbs. Self-adjusting platform and will weigh accurately on even or uneven ground. Write for scale booklet and easy payment offer.

The Value of the Pure Bred Dairy Bull in the Grade Herd

By E. S. Archibald, B.A., B.S.A., Director Exp. Farms

During the past seven years a great deal of attention has been given this subject by the Dominion Experimental Farms; and many experiments of this nature are now under way. As it takes many years to accumulate very accurate information on this subject the results of a reasonably definite nature are only now obtainable from a few farms. Following is a list of farms and stations where this work is being conducted;—

Experimental Farm or Station at:	Class of Female Foundation.	Breed of Bull Used.
Nappan, N. S.	Good grade heifers	(Ayrshire (Holstein (Guernsey
Fredericton, N. B.	Average grade cows	(Ayrshire (Holstein (Shorthorn
Ste. Anne de la Pocatiere, P. Q.	Average grade cows	Ayrshire
Cap Rouge, P. Q.	Good grade cows	French Can.
Spirit Lake, P. Q.	Average grade cows	Ayrshire
Ottawa, Ont.	Excellent grade cows	(Ayrshire (Holstein
Kapuskasing, Ont.	Good grade cows	Ayrshire
Lacoma, Alta.	Common grade cows and grade heifers	Holstein

Many factors have entered into these experiments which prohibit definite deductions to date. However, the following summaries show progress and warrant considerable study.

TWO points must, in fairness to younger cows and heifers, be kept in mind, namely;—

1. During the war feeds were difficult to obtain, hence younger generations did not have as good an opportunity as their dams at the same age.

2. These grade herds have increased rapidly and the greater numbers in itself would usually mean slightly lower production, but with war conditions of labour and feeds, with pasture shortage and similar items, there is a considerable margin of error which may be corrected during the coming year.

NAPPAN, N. S.

Experiment Established, 1911.

Summary to April 1st, 1919.

In the year 1911, eleven good grade yearling heifers representing good grade dairy heifers of this part of Nova Scotia, were purchased as a foundation. Only nine of these were used in the experiment. These turned out to be very good heifers which made good records, decidedly above the average production of grade heifers in Eastern Canada. During the first three years these foundation heifers were bred to Ayrshire, Holstein and Guernsey bulls, dropping eight, six and three heifers respectively. This was again repeated in the next three years and four, three and three heifers of similar breeding resulted. The heifers and their progeny have been bred continuously to bulls of the same breed as their sire.

During the seven years a large herd of good grade cows has resulted all springing from the nine grade heifers, and all sired by pure bred bulls. No crossing of breeds was done.

When the experiment was started there was ample pasture for the foundation heifers and first crop of calves only, but the immediate extension of pasture lands was anticipated. However, owing to war conditions no extensions materialized. Hence, the production in summer did not increase over heifer records with the foundation cows as it should have and each successive crop of heifers in milk made matters worse and did not show the advance in records proportionate with the improved breeding.

Each crop of heifers was bred to freshen at the same age and season of the year as the foundation heifers. Had pasture been available this would have made an ideal comparison, but as it was the increasing shortage of feed was an extra handicap to each successive crop of better bred heifers.

A striking point brought out in this work to date is the transmission by the bulls of different breeds of the dairy type, colour and other breed characters.

The mass of data so far collected is of such bulk that only a brief summary is here possible. The most outstanding features to date are as follows:—

1. Foundation grade heifers made excellent two year old records, but have not materially increased these as mature cows owing to above mentioned reasons.

2. The first cross Ayrshire heifers (first crop calves from foundation heifers by Aprshire bull)—50 per cent Ayrshire blood, as two year olds 71.4 per cent exceeded their dams' records at same age, 28.5 per cent as three years olds exceeded their dams at same age, 14.2 per cent at four years exceeded dams and 33.3 per cent at five years exceeded dams.

3. The second cross Ayrshire heifers (daughters of first cross Ayrshire) —75 per cent Ayrshire blood, as two pear olds 25 per cent exceeded their dams records at the same age, as three year olds again 25 per cent were superior and as four year olds 33.3 per cent were superior to their dams.

Compared with the foundation heifers at three years old the second cross heifers showed 33.3 per cent superior to grand dams.

4. The third cross Ayrshires,—87½ per cent Ayrshire blood—have not as yet had a fair chance for comparison,

SUMMARRY DAIRY CATTLE GRADING EXPERIMENT TO APRIL 1, 1919. FREDERICTON, N.B.

Table. I.

Class of Cows—Common grade at mature age	Number of days milking	Lbs. milk.	p.c. fat	Lbs. butter 85 p.c.

Average six head	75.8	2118.9	3.8	92.00

*—Heifers at two years exceeding the dams' records at maturity.

but to date have not excelled their dams to any appreciable degree.

5. The first cross Holstein heifers (first crop calves from foundation heifers by Holstein bull)—50 per cent Holstein blood, as two year olds 50 per cent exceeded their dams at same age, as three pear olds 16.6 per cent exceeded dams at same age, as four year olds 16.6 per cent exceeded dams at same age. This is not as great improvement as with the first cross Ayrshire heifers which may be due to the fact that the bull was not as good a dairy sire, but more apt to be due to the decreased pasture per head and consequent poorer summer feeding.

6. The second cross Holstein heifers, 75 per cent Holstein blood, as two year olds 66..6 per cent exceeded their dams at the same ag, which is a material advancement over Ayrshire heifers of similar breeding.

FREDERICTON, N. B.

Experiment Established, 1915.
Summary to April 1st, 1919.

1. The foundation cows were representative of the average grade dairy cow in the district.

2. The first table gives the record of foundation cows—mature age—the second pear in our possession and after the first crop of calves (grade Holsteins) were born.

3. The second table gives the record of the Holstein heifers from foundation cows as two year olds. A comparison shows that these heifers produced 2% more milk and as much fat as their dams at maturity. As three year olds these heifers are producing 30% more to date than as two year olds, and it is safe to predict that they will produce at least 33% more than their dams when mature.

4. Table three shows the foundation cows again as Mature to date in present lactation.

5. Table four shows their second crop of calves by a Shorthorn bull as two year olds in their present lactation to date in which they are equal to their dams at maturity.

OTTAWA, ONT.

Experiment Established, 1913.

Summary to April 1st, 1919.

1. The foundation grade cows were the best obtainable grade Ayrshire and Holstein cows, equally divided, and all mature. It was expected that the rearing of daughgters superior to their dams would be difficult.

2. The loss of buildings by fire in 1913 and other circumstances later necessitated disposing of many foundation cows. This coupled with the fact that the majority of cows dropped during the first two years were bulls delayed progress.

3. Only two original cows have daughters which have completed one or more full lactation periods, details of which are given herewith. At present several heifers both Ayrshire and Holstein grades are completing two pear old records, many exceeding 10,000 lbs. milk and all equal to or superior to the average mature record of their dams..

Name	Class of cow	Age	No. days milk	Lbs. milk	p.c. fat	Lbs. butter 85 p.c.	No. of Lactation avge.
1. Diamond	Grade holstein	Mature	368	11389.	3.41	457.2	3

LACOMBE, ALTA.

Experiment Established, 1913.

Summary to April 1st, 1919.

1. The foundation cows are in two groups, namely:—

A. High class Holstein Grades.

B. Common mature cows representative of the average grade cows in Central Alberta.

2. The following tables are self-explanatory. It will be seen that for both groups the progeny by a pure bred sire as two year olds produce almost as much as their dams at maturity.

3. The large percentage of bull calves during their experiment has hindered greater progress, but another year will see a marked increase in records of progeny.

AGASSIZ, B. C.

Experiment Established 1913.

Summary to April 1st, 1919.

1. A number of excellent high grade mature cows were among the original 18 foundation cows, hence progress is sure to be slower than with a foundation of poor cows.

2. During the years 1915, 1916 and 1917 the cows were used for feeding experiments which would account for lower relative production than 1914.

3. The first sire used in this work had not the same relative excellence in type and records, as the grade females, although a fairly good bull.

4. In the year 1915-16 the records of several two year old heifers from the original cows, and by unknown sires, are included in the 18 cows reported.

5. It was necessary to reduce the number of cows in 1916-17 in order to accomodate the young stock. In this year, too, heifer records are included —in consideration of which a marked increase in production is evident.

6. In the year 1917-18 all the original excellent foundation females, gone. This year's records consist of the daughters of these cows, the majority of which are two year old records. Hence in another two years when these animals are mature the grade herd should show milk production fully 30% higher than the foundation herd.

7. Much higher class bulls are now being used so it is expected that progress will be still greater.

How Contagious Abortion is Prevented and animals Affected Should be Treated

Many inquiries reach this office regarding the eradiction and control of abortion amongst cows. At the present stage of veterinary science it cannot be said that this disease can be eradicated, but there are methods that can be applied whereby it can be controlled to a degree where loss will be of small account. Some have claimed to be able to prevent an abortion, where the case is taken in time, but whenever the disease has progrssed to the point that symptoms are manifest, the conditions are such that the calf can no longer live within the diseased uterus and it must be expelled. Moreover, it is dangerous to the life of the cow to seek to retain the dead calf within her.

In many contagious diseases, where the animal survives, and immunity remains, man has been able to induce this immunity artificially through the use of vaccines. In abortion disease, too, there is a decided tendency toward immunity, but efforts toward developing a satisfactory vaccine have not been crowned with success. Main reliance, therefore, must be placed upon preventive measures rather than drugs and vaccines.

Control of abortion disease is dependent upon three fundamental principles: Prevention of the dissemination of infection, developing herd immunity, and treatment of affected animals.

Prevention of Infection

In combating abortion disease much depends upon the general herd management. The dead calf and its membranes and accompanying discharges are teeming with the germs of the disease. They should be promptly gathered up and destroyed by burning, or buried deeply. The aborting cow continues to disseminate infection in her discharges for weeks, and far more disease is spread at this time than at any other. Consequently, isolation of the aborting cow is of the greatest importance in preventing the spread of the infection. The germs may be conveyed to susceptible cows in many ways where efforts are not put forth to limit the infection. For instance, in the dairy herd, a cow aborting in the line drops the infectious material in the stable, a careless attendant tramps through it, soiling his boots; he then walks up and down the feed alleys or climbs into the silo, spreading infection wherever he goes.

Often the aborting cow becomes a "buller," and where the bull runs with the cows, he is continually transmitting the infection in an active form from the infected cow to the remainder of the herd. Do not permit the bull to serve any but perfectly healthy cows, and under no circumstances should discharging cows be permitted in the herd.

Where a cow has aborted, remove all manure and litter, thoroughly clean floor and walls and spray with compound cresol solution, one part to thirty parts of water, i.e., a 3 per cent. solution. Any other good disinfectant may be used. Finish by whitewashing, the wash being made thin and applied as a spray. Whitewash itself is a good disinfectant, and it has the advantage of being easily seen, thus serving an an indicator to show the thoroughness of the work.

Provide clean quarters, for where animals are kept under favorable conditions they thrive and amply repay for added care and attention. In cambating contagious disease, sanitation is doubly important. Disease-producing germs live for a long time in dark, damp, filthy stables, and those same conditions are unfavorable for animals, lowering their vitality and resistance toward disease. Disease germs cannot long survive in clean quarters, well ventilation and flooded with sunshine.

Starvation, the use of spoiled feed or feed containing certain poisonous principles may seriously affect reproduction, especially in the presence of infection. A varied diet containing all the elements necessary for growth, must be supplied to the breeding herd to promote vitality and the power to resist disease.

Herd Immunity

In this connection, Geo. M. Potter, of the Kansas College of Agriculture, explains that investigation has shown that approximately two-thirds of the cows that abort lose their calves but once where properly treated, and thereafter they become immune. About one-third abort a second time, and only a small per cent. a third time. It is true that in such herds the disease may continue to manifest itself for some time by an occasional abortion, a retained afterbirth, or a case of sterility, but practically the disease may be said to be under control.

Because of this tendency to become immune, the cow that has aborted and through proper treatment has been restored to health should be retained. She is more valuable in the infected herd than a new cow which in turn might contract the disease. Many a fine cow has been sacrificed because of the mistaken idea that abortion can be controlled by disposing of affected animals. Never sell a valuable breeding animal, whether cow or bull, because of abortion disease. Unprofitable and hopelessly sterile cows should be weeded out on general principles, for they require attention that should be bestowed upon the good ones. But these cows should go to slaughter.

The vigorous heifer calves which reach maturity in spite of the disease are naturally from the more resistant

cows and they seem to inherit this tolerance, consequently they are less apt to abort in turn than cows from other sources. Raise them. They will aid in building up a herd immunity.

Treating Affected Animals

Vaccnation is along the approved lines of treatment in the handling of contagious abortion, but up to the present it has not established a satisfactory immunity. Carbolic acid administered in various ways, such as in the feed, wth salt, or injected under the skin, has probably acquired a greater reputation as a drug valuable for the control of contagious abortion than any other agent. The chief reason for this is because, as a rule, no treatment is attempted until the disease has reached its maximum, and in the natural course of events there is a great reduction in the slinking of calves the following year. It is during the height of the disease that the use of carbolic acid is instituted, and it receives credit for the natural decrease in the number of aborted calves. The fact that abortion has increased, in spite of the use of carbolic acid for many years, is an indication that it is not a specfic, and is of very questionable value.

Methylene blue is claimed to have antiseptic properties, and to have specific action in contagious abortion. It was extensively used a few years ago for this purpose and inquiries are still received regarding it. Its value as an agent for the cure or control of contagious abortion was greatly overestimated, and it has almost fallen into disuse for that purpose.

Acidity of Soils and How to Apply Lime Profitably and Effectively to Them

By Prof. E. Truog, Wisconsin College of Agriculture

There are few subjects in agriculture about which there has been as much confusion as about soil acidity. There is, however, nothing mpsterious about soil acidity, and it is not difficult to get a clear understanding of it. Soil acidity is due to an excess of active acids over bases in the soil.

Soils and in fact most of the materials and substances in nature, consist of a combination of acids and bases. Chemists have found that all known material can be broken up into simple substances called elements. Some materials are composed of two elements and some of many more. After analyzing all known materials they have found that there are about 80 elements out of which by various combinations all known materials are formed.

Some elements form acids when they combine and the others form bases. Common vinegar and muriatic acid are typical acids. Lime is a base. Soaps are usually alkaline due to the excess of bases they contain. A peculiar thing about an acid and a base is that they alwaps combine with each other when they come together and form a neutral compound called salt. Common table salt is formed when hydrochloric acid (muriatic acid) and the base sodium hydroxide are mixed together. If more acid is added than there is base with which to combine then there is some acid left over and the mixture is acid from the excess of acid. If there is an excess of base, then the mixture is basic.

As was stated, the particles of soil consist of a combination of acids and bases. The soil particles of upland soils are largely mineral salts. Now, when there is an excess of acids over bases the soil is acid. If there is great excess of bases the soil is alkaline. Soil acidity thus simply indicates an excess of active acids over bases in the soil and hence can be corrected or neutralized by adding a base like lime.

All soils where the annual rainfall is 25 inches or more tend to become acid, due to the more rapid leaching away of the bases than the acids. When water comes in contact with the soil, it dissolves the bases of the compounds that make up the soil to a much greater extent than the acid constituents. As a result from 200 to 500 pounds of bases, mostly lime, are leached out and washed away per acre annually on many farms in Canada, while the leaching of acids is comparatively very small. The more a soil is cultivated the greater the leaching and the more rapidly does it become acid. Many crops also take out much more bases than acids from the soil and help to produce an acid condition. The formation of acid soils is thus not at all strange or mysterious and it is entirely natural for soils to become acid after cultivation for a number of years. Sandy soils leach readily and are usually acid even in the virgin condition. Virgin clay and silt soils are sometimes also uitqe acid.

Some fields which are situated at the bases of slopes or in the bottoms of valleys receive lime in the drainage and seepage water from the higher land and hence do not become acid or do so only very slowly. The higher parts of a field usually become acid first.

So far, purposely, nothing has been said about organic acids that are formed when green crops or manure are ploughed under, or when dead vegetation of any kind accumulates. Many writers state that soil acidity is entirely due to organic acids formed in this way. In the case of upland soils our experiments have shown that the organic matter, and hence organic acids, may be removed and still the soils remain practically as acid as before, indicating that the acidity is due largely to mneral acids, formed by the removal of bases from the mineral salts as just explained. Some upland soils contain scarcely any organic matter and yet are extremely acid. It is to be clearly noted, however, that the acidity of acid peats and poorly drained soils is often due largely to organic acids. In well drained and aerated soils organic acids soon decompose and hence do not accumulate. Ploughing under heavy crops of green manure like rye may produce an acidity due to the formation of organic acids. This acidity is temporary and usually disappears in the course of a year.

Why is Soil Acidity Injurious?

It is often stated that soil acidity is injurious because it directly attacks and injures the plant roots and directly affects the bacteria in the nodules of legumes where nitrogen is fixed. Results of our recent experiments do not agree with this. We find that when soils become acid the supply of available lime and other bases in the soil becomes too low to meet the plant's own need for these. An acid condition is simply the positive indication that the supply of available lime is getting low.

It is to be clearly noted that even acid soils still contain lime that is bound up with the soil acids, but since there is an excess of soil acids, all of which try to hold on to the lime, it makes it extremely difficult for some plants to get sufficient lime unless more is added to the soil.

In the processes by which plants build up the different compounds of which they are composed, various acids are formed that must be neutralized, or else the plant sap becomes so strongly acid that the growth processes are interfered with or stopped. In order to neutralize these acids, the plant must get sufficient lime from the soil. If the growth of legumes is lowered or stopped by a lack of lime or any other cause, then nitrogen fixation in the nodules by the bacteria is also lowered or stopped. The nitrogen which is fixed is a by-product or waste material of the bacterio in the nodules and must be removed by the plant in order for the bacterial activity to continue and make possible the fixation of more nitrogen. The legume plant is not able to remove this nitrogen from the nodules unless other conditions are such that it can grow normally and thus have use for this nitrogen.

Plants like alfalfa and sugar beets require large amounts of lime and have comparatively weak feeding powers and hence are affected greatly when a soil becomes acid. It requires about 100 lbs. of lime carbonate to produce a ton of alfalfa. A ton of red clover requires about 75 lbs. Oats, rye, wheat, and corn require only about one-fifth as much lime as alfalfa.

Cabbage, lettuce, and most all garden crops require large amounts of lime. Gardens should always be limed if the soil is acid. It is thus very easy to understand why some crops like alfalfa, clover and sugar beets are affected by an acid soil much more than crops like oats and hay. The oat plant is low in lime and has very strong feeding powers. It grows much better on acid soils than barley which is higher in lime and has weaker feeding powers. A liberal supply of lime is necessary to make good barley soil.

A good supply of lime insures successful inoculation and nodule development of the legumes. It also makes the nitrogen, phosphorus and potassium of soils more available. It favors early maturity, hardiness, and freedom from disease injury. It helps to prevent lodging of grain. Lime improves the physical condition of both heavp clay soils and sands by making the clays more open and workable and the sands more compact. An abundance of lime prevents the accumulation of soluble toxic or poisonous substances in soils. Lime is really the great regulator of soil fertility.

There are only a few cases where an excess of lime may be detrimental. Potato scab and possibly a root disease of tobacco are favored by a large excess of lime. When the potato scab and root disease of tobacco are properly controlled, lime increases the production of both. Of the garden crops, the watermelon is the only important one that usually grows better on an acid soil. This may again be due to plant diseases which live in the soil and are favored by lime.

How Test for Soil Acidity and the Need for Lime?

Since soil acidity indicates and is due to a lack of lime, the test for soil acidity tells whether or not lime is needed. The litmus paper test has been used a great deal in the past for this testing. To make this test, blue litmus paper is placed in close contact with the moist soil and left there for five to ten minutes. If the paper turns red the soil is acid. The great trouble with the litmus paper test is that it does not tell how acid the soil is and hence how badly or how much lime is needed. When soils are only slightly acid the results are often confusing and unsatisfactory. The paper must be handled with great care and it fades when exposed to the light. Carbonic acid, which is always present in soils, and is beneficial rather than harmful may also affect the test.

In taking this sample select an average spot of a few square rods and take from this small area a little surface soil from five or six places so that they will make altogether a sample of about one-half cupful. If the field varies widely in fertility or topography, it is best to take several entirely separate samples from different parts of the field. If part of the field is high land and part low land, a separate sample should be taken from both places, and in no case should the soil from high land be mixed with soil from low land in making up a sample, as the results then will not mean anything. Samples from different fields should never be mixed.

Different parts of the same field, and especially the different fields on the same farm often vary greatly in acidity. Always test your soil before applying lime because some soils do not need liming. It is very profitable to put lime on acid soils, but a waste of time and money to put it on soils that are not acid.

PASTURE VS. SILAGE FOR THE DAIRY COW

Good pasture is generally acknowledged to be the ideal feed for the dairy cow. In a great many dairying districts it is very difficult to get good pasture throughout the entire summer season. Usually good returns are obtained by supplementing the pasture with concentrates, soiling crops, or other feeds. Of late years a number of dairymen are using silage as a supplement while others confine their cows in the barn and feed silage entirely. This latter practice has been in vogue for a few years at the Experimental aFrm, Agassiz, B. C. The chief criticism is that it seems an unnatural way of handling cattle, but it has nevertheless given good results. During the hot weather the cows are put in an exercising paddock at night and kept in a barn with screened windows during the heat of the day, while during cool weather the cows are alowed in the enclosure in the day time and stabled at night. By handling them in this manner little trouble is experienced from flies or excessive heat and the cows are handy at milking time.

The big factor in favor of feeding silage as compared to pasture is the fact that the former method allows of more intensive farming and consequently a great number of cows per acre may be obtained. It requires very bood grass to pasture one cow per acre for six months of the year, while a fourteen ton per acre crop of corn made into silage will feed two cows for six months. In other words, practically double the number of cows may be kept when silage is fed as when the cows are pastured.

From the standpoint of production, the pasture feeding gave the best result sin a fifty-day trial carried on last year comparing the two methods. Ten cows on pasture from May 8th to June 26th gave 12,860.9 pounds of milk, while ten cows fed silage gave only 10,848.2 pounds of milk in the same period. Figuring pasture at $2.00 per cow per month and silage at $5.00 per ton, with concentrates at market value, the milk cost 52 cents per 100 pounds more from the silage fed lot. The silage lot of cows were given daily exercise in a bare paddock and fed silage in the barn, while the pasture lot were on grass all the time except during milking hours. Each lot had the same grain ration. It must be remembered that this test was conducted in early summer before the flies became troublesome and while the pasture was excellent. Later in the season the pasture was dry and bare and the flies caaused great inconvenience to the cattle on pasture.

If good pasture is obtainable it is to be preferred to silage for feeding dairy cattle, but if good silage is on hand it may be used with excellent results to suplement the pasture at such times as the pasture may prove unsatisfactory.

W. H. HICKS,
Supt. Experimental Farm, Agassiz, B.C.

THE MARITIME FARMER

And Co-operative Dairyman
Registered Trade Mark
Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definite order for discontinuance is given,

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsible advertisers. To take advantage of this guarantee, written complaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said:—"I saw" your adv. in the MARITIME FARMER.

Sussex, N. B.

NOTICE TO ADVERTISERS.—Changes of ads. should reach this office one week before date of issue, in order to insure insertion.

RECEIPTS FOR FARMER SUBSCRIPTIONS

The Maritime Farmer, instead of giving you one receipt in the year for a paid subscription, sends you 24, or one every two weeks. You will find it on the GREEN COLORED LABEL on which your address appears. The date printed thereon is that on which your subscription terminates. If on payment of your subscription the date is not changed within two weeks, please notify us. No other receipt will be sent.

WHERE THE FARMER STANDS

The thing that country life needs most is to have its own leadership, its own self direction, and self dependence and downright faith in itself. The most important development so far as agriculture and farm life are concerned, is not the science of experiment stations, its appilcation by progressive farmers, the building up of great agricultural colleges, nor the discoveries and inventions that have changed the whole mode of life. Valuable as all these things are, they would be a sad failure if they were not giving the rural communities the men and women who understand the true relation of farm life to the national life better than outsiders can know it. There are in rural life today men and women of intelligence and fair-mindedness who have a right to do their own leading. They are capable of doing their own thinking and do it in a straight line. They realize that they belong to a democracy and not an autocracy that doles out pittances when only dire need is apparent. The growth of true democracy is seen in every assemblage of the rural people. Rightly constituted they are the reflections of the best judgment of the community as to what discussions and conferences are needed. Farmers are now realizing their responsibilities, and it is only when they accept responsibility collectively, that they can work constructively and have less occasion for regrets or protests later.

GIVE THE BOY A CHANCE

It has been said, and it is absolutely true, that not very much can be done with most adults, for the simple reason that their ideals are in the past. In view of this, therefore, the great hope is with country children, but, greatly to be regretted, too few parents appreciate the importance of the boy, or realize that he is the sole connecting link standing between them and the wonderful future.

A boy's place on the farm is a large one. There is no use denying that; one might as well debate on the value of daylight. Yet many farmers do not begin to appreciate this all important matter as they should, nor do they accord the boy his proper fitting in the general scheme of things. In this conection the late Theodore Roosevelt once fittingly said: "If you wish to do anything for a man, you must begin before he becomes a man. The only hope of success lies in beginning with the boy, so if we wish to have the best farmers in the land, and more of them, we must train the boys in scientific agriculture."

The study of any subject not only begets knowledge, but also interest in it. If a boy can be persuaded to study agriculture, his interest in it gradually increases until he becomes a scientific farmer for life. For this reason more time should be devoted to the study of agriculture in our rural schools.

THE FARMERS FORWARD MOVEMENT.

After years of unusual exertion, surrounded by unprecedented conditions, farmers of Canada have gathered, more than ever before, a definite idea of the profundity of their farm resources, and the astonishing results of their accomplishments. From the depth of this new experience there arises today a farmer with a new vision, a clearer understanding, and a more resolute determination to win for himself a moderate allowance of prosperity that will adequately measure his investment of brain and brawn in the tillage of the soil for the sustenance of mankind.

His experience is generating a desire for greater liberty and he is meantime estimating the handicaps which impede his progress toward that end. He no longer remains satisfied with the lack of knowledge of the problems that affect his progress to successful issues. He is resolved to fit himself in every possible fashion for the larger accomplishments which he knows now he can attain and has demonstrated as possibilities.

Many of the barriers to the success of his business he recognizes as artificial, and is setting his face resolutely to the task of removing such obstacles that interfere between his unremitting toil and the fair reward he considers should attend it. In these respects the farmer is distinctly looking forward.

BETTER AGRICULTURAL TRAINING NECESSARY

If agriculture is to develop, it can only be done through the highest planes of science, for it is only by that method that the greatest knowledge can be evolved, and diffused among students fitted to apply it in practice. If those who engage in other industries require a university training to fully equip them to keep up with the progress of the times, then surely those that are engaged in agriculture, the greatest of all industries, deserve to get the same training. It is vital then that agricultural colleges should have a high status both for teachers and students, and like technical colleges should be kept in closest relationship to the universities that is attainable. It is a country's duty to give every facility to raise the whole agricultural community to a high intellectual level, from the farm worker to the farmer. It is on knowledge that the future of the tillers of land in this country really depends more than on anything else. That knowledge will do little good, unless it is not only sufficiently widespread, but also adequate in its quality.

Universities in the future must enlarge the scope of their work, and have special courses for agriculture, business organization, banking, salesmanship, advertising and technical training. A nimal and plant life as itmere knowledge of the a affects the success of farm husbandry is not all that is necessary in farm business. It is vital to the interest of the farmer to have the knowledge of how to conduct the business necessary to reaping the full reward of his labors.

THE CALL OF THE COLLEGE

This is the time of year when the college calendar is really popular. All our higher institutions of learning are bidding for the young manhood and womanhood of the country. This is good and wholesome. We have never yet heard of anybody who regretted his college course. We have heard some folk say that it doesn't pay to go to college because many people who have gone are not making as much money as some people who never went. Needless to say, this kind of argument comes from individuals who were denied the privileges of higher education.

On another page will be found the announcement of the College of Agriculture, Truro. This advertisement should have particular interest for Maritime Province folk, and especially the farming population of that area. The College at Truro is the only one of its kind in the East, and it has a most honorable and enviable record.

Prior to the war, in the year 1913-14, there were in attendance 114 in the regular classes, and 350 at the Short Course. Although this is by no means the capacity of the college and falls far short of the ultimate goal in enrollment, yet it is relatively high in comparison with other institutions of the same nature. Practically all the students in the regular course and from 80% to 90% of those in the Short Course, with the honorable exception of those who fell in the great conflict, are now farming, and the great majority in eastern Canada. Every one who is conversant with rural conditions knows what an impetus these men have given to the higher type of agriculture in the Maritime Provinces.

During the war, as at all higher educational institutions, the attendance was greatly reduced. But now that the war is over the College is planning to prosecute its work more vigorously than ever. The time is most opportune for young farmers to carefully consider their duty to themselves, to those who will in time be dependent upon them, and to the country which has given them so rich a heritage. One or two winters spent at the college is the very best kind of investment for the future. Apart from the knowledge of farming methods, and of the scientific principles which underlie these, they would have opportunity to improve themselves as citizens of the country, and to realize the highest form of patriotism.

Although the College of Agriculture is located in the province of Nova Scotia, its classes are alike free to students from the three Maritime Provinces. The term begins on the 4th of November, after the main activities of farming are over, and closes in April, in good time for the spring work. We would strongly urge those for whom there is any possibility of attendance to write at once for information. It will do no harm to write even if there seems to be no possibility of attendance.

* * *

The small, well pruned and well cared for orchard is worth more to the farm than the large one uncared for. Cut out the trees that are not wanted.

Progressive communities draw men who are looking for the best land with proper surroundings supplied by development.

Gleanings From Nova Scotia Agricultural College

THE SILO

A striking testimony to the value of the Oats, Peas and Vetches mixtures (O. P. V.), which has been so strongly recommended by Professor Trueman, of the Agricultural College, came to our attention recently A dairy farmer living some 40 miles from Halifax erected a silo two years ago, filled it with the O. P. V. mixture last fall. He had abundance of feed for his dairy cows, and, in addition, in a year when hay was scarce, sold over $700 worth of hay. This he holds, and rightly so, to be clear profit from the silo, without which he would have been compelled to buy hay instead of selling it, or to reduce his stock.

Quite a number of silos have gone up during the past two years for ensiling this mixture. The experience of this farmer indicates that there should be many more. Two or three facts may be simply indicated here with regard to this kind of ensilage. The O. P. V. mixture is hardy and well adapted to the Maritime variety of climate. It is capable of a yield of 12 tons to the acre (this was attained on the College farm last year) and is very high in food qualities. A recent rough estimate of the cost of a silo runs thus,—

	tons	cows	costs
10 by 20	28	7	$225
10 by 22	31	8	$240

Any farmer who is interested and wishes further information on the matter should write to Professor Trueman at tht Agriculeural College, Truro.

A SPRAYING CALENDAR

Those who have been watching the experiments conducted by Professor Brittain of the Provincial Dept. and Mr. Saunders of the Federal Department, have been much impressed by the excellent results following the use of a spraying calendar issued by these men last spring. It indicates the composition of the sprays used and the proper time to use them in fighting the various foes of the orchard.

Trees sprayed according to directions are very free from scab and vermin, and the fruit free from russeting. It is also evident that the trees so sprayed have suffered no ill effects by burning. In short, this publication is a decided step in advance and deserves a wide circulation. By the way it is worth mentioning that the poisons prescribed effect a considerable saving over those formerly in general use.

PASTURE IMPROVEMENT

The pasture lands of Nova Scotia were never in better condition than during the present year. It has been an unusually favorable season for vegetation of every kind. For this reason it may seem less necessary to speak of the improvement of pastures. But those who should know best, and doubtless do, say that the time to improve pastures is not when they are thin and burned with drouth but when they are at their very best. The Farm Superintendent at the Agricultural College has for several years made it a practice to apply a moderate quantity of fertilizer to fairly good pasture land, and by this practice has so improved it that some 60 acres of grazing land is this year carrying 37 head of live stock. They are in splendid condition and are not able to keep it eaten down. fThe practice at the College is to apply fertilizer in the fall, going over the pasture lands about once in three years with, say, 500 lbs. per acre of basic slag, wood ashes, or some other brand of equally good fertilizer. Experiments have shown that a top-dressing in the fall will not give good results on sparse pastures. However, the experience of the College is that it pays very decidedly—in fact few operations pay so well, to treat pasture lands in this fashion.

It is important to remember tnat in these years of soaring prices the cost of producing beef, mutton, milk, etc., on pasture has not materially increased. This will still be true when it has become the general practice to apply either artificial fertilizer or even the much wanted barnyard manure to pastures. A smaller area will carry the herd, and the yield will be increased with the richer grazinig. In any case the added expense does not campare for a moment with the increased cost of feeds used in the stable.

One does not need to argue at length that it is good business these years for the farmer to concentrate as far as possible on the summer season for heavy milk and meat production. The cold storage movement now underway will obviate the old difficulty of an overstocked market. The two important steps to be taken to meet the mill feed situation are, without doubt, to grow and to store silage feeds and to secure the best possible pasturage.

An expert who has recently looked over the agricultural situation in Nova Scotia states that the most practical thinfi which can be done at the present time by N. S. farmers in order to secure a larger revenue at the minimum of outlay is to improve their pastures. This expert pointed to the fact that good grazing is the secret of the high class live stock of the Old Country. There, farmers top-dress their pastures with fertilizer and manure as carefully as they do their arable lands. An illuminating commentary on the whole question appears in Professor Trueman's article in the Report of the Secretary for Agriculture, issue of 1919.

SIDE LINES IN FARMING

It is a well known fact that many men who are now among the blessed ranks of the independent made their first start towards success through some sideline, which, in itself was relatively unimportant. This furnished without much labor or expense the extra cash return which meant the difference between debt and forehandedness. Among these the most common have been the poultry flock, the strawberry patch and the early market vegetable plot. Here and there we hear of one who gives first place to the honey bee. The writer heard recently of a leading orchardist in the western counties who states that this busy little creature gave him his first lift.

The present is an unusually favorable season for honey production. One gentleman in the heart of one of our towns had at the begining of August taken $120.00 worth of honey from five hives. Besides this his assets have been increased by two new colonies, worth $25.00 or $30.00. Another man in the same town who just begun last spring with two hives has secured $30.00 worth and expects as much more before the season closes. The wintering of bees is always attended with an element of uncertainty, but apart from some degreee of knowledge of their habits and a bit of watchfulness they require but little labor.

ANOTHER HUN BEATEN

Among the most exasperating pests that afflict the market gardener and vegetable grower generally is the cabbage maggot. It will be good news to these to hear that Professor Brittain of the Entomological division, Truro, and his assistants, have been most successful in their work for the elimination of this pest. They have tried out a number of methods of dealing with this foe, all of which have been more or less successful, but there are two comparatively easy methods of treatment which they recommend in place of the older tarpaper disc treatment.

1. The application of a solution containing corrosive sublimate, in the proportion of one part of this poison to one thousand of water, 1 to 1000, or, one tablet of the usual commercial size to a pint of water. This liquid is poured about the roots of the plant in the early stages of its growth. Two applications during the season gave perfect results at the College.

2. The application of a creosote preparation. In this treatment the creosote is mixed in the proportion of one to one hundred, 1 to 100, with clay, and the mixture, ground to a fine powder, is thickly sprinkled in a dry condition on the surface of the ground around the plant. It is necessary to renew the application after each cultivation.

Both these methods have been thoroughly tried out, and both have given perfect results on the experimental plots.

ANOTHER LEAN YEAR IN MILL FEEDS

Nova Scotia as a whole, and particularly her farmers have reason for profound thankfulness for an unusually bountiful crop of hay, and the promise of a heavy yield in grain and roots as well. It wil be necessary to bear in mind, however, that a arge portion of Canada has suffered severely from drouth. The Secretary for Agriculture, who has recently returned form a trip through parts of Ontario, reports that there will be little if any grain available for shipment either from that Province or from large areas further west. Consequently the indications point to a mill feed situation at least as difficult as the past two years, with equal scarcity and high prices. Substitute feeds which were available in considerable quantities last year from the United States are also being swept up by the starving markets of Europe.

Every possible measure should be taken in view of these facts to conserve our resources in feeds. Orders should be placed at the earliest possible date with the feed merchants for the winter's supply. Whatever opportunity there is to obtain such supply will fall to the early purchaser. One leading authority in Montreal who is familiar with feed and feed conditions when asked by an eastern representative when it is best to buy these commodities, replied: "Buy whenever you get a chance to buy, for you may not get another chance."

TIMOTHY AND CLOVER SEEDS

Many farmers learned through disappointing experience last Spring that it is unwse to delay placng orders for Tmothy and Clover seeds. Those who were late either had to go without or had to pay extremely high prices. Reports of the seed situation indicate a recurrence of the shortage in both these commodities. As a mere matter of routine it is always good business to place a necessary order early, especially in these days of bare markets. The late duplicate order is subject to extra shipping charges, liable to be delayed beyond the period of usefulness, and is almost certain to find prices advanced. Those who have inside knowledge of the seed trade in these two lines particularly advise the placing of orders for next season's Timothy and clover seeds even at the present time.

ONTARIO HOLSTEINS FOR NOVA SCOTIA

Dickie Bros., of Truro, N. S., both of whom have lately returned from overseas, are taking over the farm of their father, Mr. Samuel Dickie, and increasing the herd of purebred Holsteins. It will be remembered that this herd includes the great cow, Miss La Honda, holder of the world's record for three days butter fat production in public dairy test.

Mr. Walter S. Dickie recently visited Ontario and selected a carload of females from herds in the Brant distrct. From Oak Park Stock Farm, Paris, was secured the beautiful two year old heifer, Lady Hengerveld of Oak Park, a daughter of the grand champion bull, Lakeview Dutchland Hengervald 2nd, and herself a show heifer of high class. From Mr. F. S. Passmore's herd at Brantford Mr. Dickie selected a choice cow with a good record in Patsy B. Mercena, also a two year old daughter of this cow, Patsy B. Hartog. This is another show heifer, sired by a brother of the 33-lb. cow, Jenny Bonerges Ormsby. The 1600-lb. cow, Pauline Hartog, of beautiful lines and with an excellent record came from the herd of Wellington Sager & Son, St. George, along with the three year old, Julia Netherland Baroness, one of the choicest things in the Plant dispersion sale last spring. Three head were added from the herd of Mr. G. W. Clemons, St. George, Evergreen March 5th and Maple Hill Edith, two excellent daughters of Prince Pieterje March, also the heifer calf from the later cow. From the herd of Mr. G. B. Robb, Branchton, one cow and five two year old heifers were selected. The cow looks like a winner in the show ring and is a daughter of Summer Hill Ormsby, a $1500 son of the five times 30-lb. cow, Jenny Bonerges Ormsby. The five heifers were an excellent lot, all heavy in calf and showing good indications of production. They were all sired by Maple Hill Danforth, son of Choicest Canary and Evergreen March 2nd, while all their dams were got by Summer Hill Ormsby.

This was a very typey lot of cattle, and, as they arrived in Truro in good shape, should prove a notable addition to the Dickie herd. Messrs. Dickie have been using high class bulls for years, including a son of Madam Pauline Canary 31.76 pounds, and a son of Wadmantje Canary 33.00 pounds and 781.25 pounds in a year at four years.

A bull calf from Miss La Honda and sired by Prince Colanthuc Canary A., the son of Madam Pauline Canary and Prince Colanthus Abbekerk, is one of the stelar attraction in the Nova Scoti aherd, and breeders who are seeking type eand production combined should have a look at this young fellow.

EARLY MOLTERS ARE SLACKERS

A hen which selects a new coat of plumage ebefore October 1st is unpatriotis and a slacker. She should be condemned and executed. The early molter is a loafer, while the later molter is a heavy layer. Hens rarely molt and lay at the same time and an early molter has gone on a striike before eshe should. The poultry man will do well to rid his flock of this kind, says H. L. Kempster, of the University of Missouri College of Agriculture. Many people have the idea that an early molter will be a layer next winter. Studies at the Missouri Experiment Station indicate this is the exception rather than the rule. A late molting hen will lay just as many winter eggs, if not more than the early molter; so the poultry man will make no mistake in selling the early molting hen.

HORTICULTURE.

HOW TO KEEP UNDER CONTROL MANY OF THE INSECT PESTS THAT INFEST GARDEN CROPS

Successful gardening depends to a great extent on the ability of the gardener to keep under control the many insect pests which infest garden crops.

To begin with, it is well for the gardener to know that two kinds of insect pests are recognized. One kind sucks the juices from the plants, and the other kind eats the leaves and stems. It is necessary that the gardener know the complete life history of every insect that inhabits his garden, but it is essential that he know their vulenrable points and the methods to use against them.

Some methods are largely preventive while others are curative. To be effective, a proper remedy must be applied at the proper time. As a rule, insects do the greatest amount of damage during their larval stage.

Tiny as the aphids or plant lice are, they are for the worst enemy of the gardener. Not because they consume a greater quantity of food stuff than the leaf eating insects, for that is not the case, but because they feed on the under sides of the leaves and, therefore, destroy much vegetation before their presence is known. And how they multiply! Only half a dozen in the garden today will mean thousands in the course of two or three weeks. When the leaves of a plant curl up or turn yellow, you may be almost positive that aphids have taken possession. Aphids generally do the most damage to crops that are grown on poor soil, crops that are late planted, or crops that have been poorly cultivated. On strong, vigorous crops these insects do not gain a firm hold, but they will practicaly destroy an inferior crop.

One sort of aphids known as thrips cause much damage to onion crops. The leaves are the object of their attack. When attacked, the leaves first assume a dull gray or dirty appearance and within a ashort time, turn brown and die. Kerosene made into an emulsion is one of the most effective remedies. A standard solution of Bordeaux mixture is also recommended. This mixture should be composed of water four gallons, fresh lime one-half pound, copper sulphate one-fourth pound. Any quantity may be prepared by using the ingredients in the same proportion.

The cucumber is also the victim of an aphid which does much harm in a comparatively short time. The cucumber being a very tender plant, it will not endure the severe methods employed for destroying insects on more hardy plants. An excellent remedy is to spray the plants with a ammoniacal carbonate of copper solution. This is made by dissolving one ounce of carbonate of copper in one-half pint of strong ammonia (26 per cent.) This, of course, is a stock solution and before using should be diluted with 9 galons of water. White or whaleoil soap made into an emulsion will, under ordinary conditions, answer the purpose admirably.

As stated before, insects that eat the leaves of plants must be poisoned by introducing poison into their food. Paris green was, for years, the usual poison used for this purpose but of late years, arsenate of lead has replaced it to a great extent. The drawback to using Paris green is that it is washed off by the first rain, while the arsenate of lead will adhere to the plants for weeks. Arsenate of lead can be purchased in packages just as Paris green is purchased and the mixture generally used is six ounces of arsenate of lead to five gallons of water. Arsenate of lead is harmful to stock and must be used with caution.

Hellebore is a mild poison and although not so sure as the arsenate of lead, it will answer the purpose very well and with little or no danger to stock, as it soon loses its virulent qualities aafter exposure to the air. It may be used as a spray, one ounce to two gallons of water, or mixed with a little flour and dusted on the leaves when they are wet with dew. Hellebore is especially adapted for use against the voracious currant worms. This pest begins its work early in the spring and starting at the bottom of the plant eats upward, doing a large amount of damage before he is discovered. A spray of hellebore early in the spring will do much toward saving your currant crop from this pest. A second brood, some two weeks later, should be watched for. If you kill these you will have no more trouble.

Grasshopers do much damage to garden crops although they are noticed but little by the gardener. It is a great lover of celery during the early part of the season and many celery crops have been almost ruined by this "king of jumpers." A poison composed of wheat bran to which there has been added molasses and water and enough Paris green to give the mixture a slight greenish color, will do the work.

The celery leaf tier is another enemy of the celery plant. It not only destroys the leaves by eating them, but spins a web and ties the leaves together. Hand picking is the most effective means of controlling this insect. The most harmful of all celery insects though, is the celery caterpilar and the zebra caterpillar is, though much smaller, a good second. Both caterpillars can be controlled by hand picking.

Cutworms are the hidden enemy of the gardener and are, indeed, most vexatious pests. They hibernate during the early spring. They feed at night and prefer fresh food, for this reason many of them may be poisoned before time of setting out plants by spraying a plot of grass with a mixture of one eounce of Paris green to five egallons of water, mowing the grass and dropping it in handfuls of five or six yards. Many of the worms are attracted to the grass and poisoned. The poisoned grass should be distributed on the ground in the evening. Another preventive measure against the cut worm which provides good results is to provide a little paper colar for each plant, when setting them out. These collars are merely strips of stiff paper fastened at the ends with toothpicks. They should extend an inch or two below ground and two or three inches above. If these preventive measures are followed you should have little or no trouble with cutworms. However, if you have allowed them to get a start in your garden you may save your plants by placing a good vermine on the ground around the plants. This should end the career of both cut-worms and grubs.

Don't give up in despair when the cabbage worm makes its appearance. Spray your cabbage plants with a mixture of one ounce of white hellebore to three gallons of water and watch what happens to Mr. Cabbage Worm. Some degree of success has been attained in controlling the cabbage worm by the use of sot or salt.

The striped cucumber beetle and the cucumber patch has a hard time waxing fat at the same time, and if the cucumber beetle is not taken in hand at the proper time, there will be nothing in the patch but the beetle. There is no specific remedy for this insect, but direct applications of poison will destroy the beetles when they occur in moderate numbers. Mix arsenate of lead with finely sifted plaster or similar diluent in the proportions of one to seventy-five by weight, and dust over the young plants early in the morning when the dew is on. Topical applications are inefficient when the insects are most abundant, therefore, recourse must be had to other measures, a good repellant being the most successful. Land plaster or gypsum saturated with kerosene or turpentine is an excellent repellant. Tobacco dust sprinkled on the hills, particularly when the soil is moist, is also an excellent repellant.

Besides the insect thrips, mentioned elsewhere, the onion is attacked by the onion maggot. This pest works at the roots of the young plants and is very destructive. There is no entirely satisfactory means of combating it, but one of the best remedies is to apply sand which has been previously soaked in kerosene to the base of each plant. A cupful of kerosene to a bucket of sand will make the correct mixture and a handful of sand is sufficient to place at the base of each plant. This keeps away the flies that lay the eggs from which the maggots hatch. Saltpeter placed close to the plants, but not allowed to touch them, just before a rain, is also an excellent remedy.

Hand picking is the only sure way of ridding your tomato plant of the tomato worm. They are not often present in large numbers and any of the poison sprays will affect the growth of the plants.

Concerted action is what counts in dealing witih the insect pests. So don't be discouraged but go right ahead with the garden.—G. A. R.

FUNGUS DISEASES EASY TO CONTROL

Most diseases of plants are caused by low forms of vegetable life known as fungi which live upon and within the tissues of the higher plants. They are thus parasites which obtain their nourishment by breaking down the cells of the plant on which they exist. The main difference, other than size, between the fungi and the higher plants is the lack of the green coloring matter so abundant in the higher order of vegetation. The methods of development in the fungi are very similar to that of the higher plants, but their microscopis size renders their study more difficult. The parasitic fungi spenr the winter mostly within the living and dead vegetable tissues and during the first

Carhartt's Overalls

are made for hard service

YOU have only to examine them to find that out. Every seam is double stitched, every button is riveted, while points where the strain is hardest are reinforced to prevent tearing or ripping. Special features worth noticing are the angular rule pocket, the swing pocket to keep tools and pencils in place when you bend over, lined watch pocket, and an extra rule pocket on the right leg. You'll be surprised at the way your Carhartt's will wear and wear and wear. You'll say when the time comes to discard them—and you may depend upon it that won't be for a good while—"Well those Carhartt's certainly don't owe me anything." My Carhartt overalls, allovers and gloves are readily identified by the car-heart button.

Hamilton Carhartt President, Hamilton Carhartt Cotton Mills, Limited Toronto, Montreal, Winnipeg, Vancouver, Liverpool, Eng.

Eureka POTATO DIGGER

Saves Extra Help

Pay for your Eureka Potato Digger with extra money earned by getting the whole crop early and selling while prices are high. Get the crop before it freezes in, without extra help.

The Eureka works in ground and conditions where other diggers fail. Its Eureka elevator and duplex rod provide more separation; its big wheels and main gears give big power; its high clearance over shovels prevents weeds and vines bunching.

Has vine-turner attachment: Special construction prevents frequent breakage. Growers report digging 150 and more acres without repairs.

Adapted for use with tractors; with or without engine attachment. 6 and 7 ft. sizes; several styles.

In stock near you. Write for catalog.

Fruit Packages

We Manufacture Strawberry Boxes and Crates for same, 6 qt Baskets, Apple Boxes, Box Shooks, Apple Graders, Wheelbarrows. Now is the time to lay in a supply of Fruit Packages for the coming season. We have a good stock on hand, order early and ensure prompt shipment. Price on application to

Hantsport Fruit Basket Co., Ltd.

HANTSPORT, N. S.

warm days of spring send out small spores which correspond to the seeds of the higher plants. These spores are disseminated by the wind and otherwise from plant to plant. With favorable conditions as to moisture. the spores send out small branches which penertatee into the living tissues of the higher orders of growth. Here new branches are formed in immense numbers which soon sap the vitality of the plant and cause it to become diseased. New spores are developed on the exterior of the plant from time to time, but more especially in damp warm weather, and thus a fungus disease may become widely disseminated in a avery short time.

By the application of a fungicide to a plant it is possible to destroy the spores which have found lodgment upon it and thus prevent the development of additional spores which would cause disease. Just as long as the tissues of plants are covered with a thin even coating of a fungicide, no fungi can develop upon them. Thus, if a fungicide is applied at regular intervals of about two weeks during the spring and early summer, a plant disease may be held entirely in check. Thus a fungicide is a preventive and its application should begin long before the disease has advanced far enough to manifest itself to any extent. The application of Bordeaux mixture is thus a good plant insurance. Applied to potatoes it causes the vines to remain green much longer than would otherwise be the case and this in turn causes the formation of larger tubers. It thus increases the yield of potatoes more than enough to pay for its application, even though potato disease may not be present.

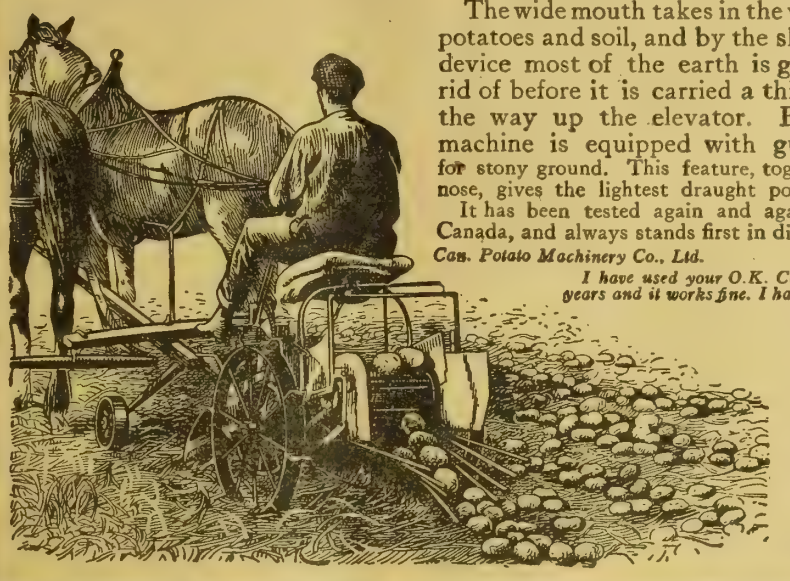
Some fruits—the apple, grape, peach, and plum—are nearly always susceptible to fungous diseases and should be regularly sprayed with Bordeaux mixture every two or three weeks during the spring and early summer. This will do much towards insuring a good crop each year.

Potato Digging Costs Half
With the O.K. Potato Digger

The cost of labor is exactly half of what it is when a plow is used to take up the crop. The work is done in half the time, is done more easily and the potatoes are not injured.

The O.K. Digger gets the potatoes out of the ground without bruising or splitting. It leaves them clean on the field where they can be quickly gathered up. The nose and working parts of this machine are strongly made, and can be used year after year without trouble.

O-K
Canadian Potato Digger



The wide mouth takes in the vines, potatoes and soil, and by the shaker device most of the earth is gotten rid of before it is carried a third of the way up the elevator. Every machine is equipped with guards for stony ground. This feature, together with the specially designed nose, gives the lightest draught possible in a potato digger.

It has been tested again and again by farmers in every part of Canada, and always stands first in digging efficiency.

Can. Potato Machinery Co., Ltd. *Mindinroya, Ont., Nov. 20, 1918.*

I have used your O.K. Canadian Potato Digger No. 1 for eight years and it works fine. I have dug eighty acres with it. With a few neighbor boys and the digger, digging is a short job. Yours very truly,
(Signed) Wm. Couley.

SMALL FRUITS FOR FARM GARDENS

While few families in cities and towns are without fresh strawberries, raspberries, gooseberries and currants during their season, many farmers' families have not a plentiful supply of these fruits although they can be so easily grown in the country. **Farmers who have made a practice of having a good fruit and vegetable garden would not be without one** and, notwithstanding the difficulty of getting help on the farms, the home garden is usually cared for, once the benefits of having one have been experienced. All the household is deeply interested in the garden and if the farmer will take half a day or a day to get some of the rough work done before the rush in the fields begins, the necessary care during the season will usually be given by some other member or members of the family. A beginning might be made this autumn.

The strawberry, being the first of the small fruits to ripen is, perhaps, appreciated more than any other. For the area of land occupied it gives the best returns. To obtain the best fruit, the ground should be rich and the plants must not be too much crowded. In the home garden it will be found well worth while to place runners as they develop so as to space the plants from five to six inches apart each way and then keep the surplus runners cut out. A fruiting row about two feet wide is desirable unless there is only one row in the garden when it may be left wider. Varieties suitable for the home garden in Eastern Canada are Senator Dunlap, Parsons Beauty, Bubach and Wm. Belt. In the warmer parts of British Columbia, Marshall, Royal Sovereign and Paxton are three which are especially good for home use. A well cared for strawberry row in a garden should give a pound of fruit for every lineal foot of row. It will be found best not to take more than two crops off the same row and only one crop would be even better.

The raspberry is the next most important small fruit. A single row across part or one end of the garden or along one side may be found the most convenient place. The plants may be either kept as single plants or in hills five feet apart each way and about six canes left to a hill, or in rows, the original plants being three feet apart in the rows and kept in hills or left to become a continuous row, and if more than one row is planted there should be six feet between the rows. The canes should be kept well thinned out if grown in a row and not left closer than six inches. If very close the canes will be too small to produce the best crop. In plantations already established it wil be found to be desirable to cut out the fruiting canes as soon as possible after the fruit has been picked and remove the weak canes of the current season's growth so that the strong canes will develop well. The purple, non-sucking varieties of raspberries, such as Columbian and Shaffer, as propogated by covering with soil the long, slender tips of the new canes, in August.

These tips will root and the rooted plants are cut away from the cane late in the autumn. The Herbert is the hardiest and one of the best varieties for home use, but Cuthbert is very good also and is particularly good for preserving, as it is firmer than Herbert, but it is not so hardy. Columbian is the best purple raspbery. Thirty-six lineal feet of Herbert raspberry produced fifty pounds twelve ounces of fruit in one season at Ottawa, but if half of this amount were gathered in the average garden from this area, takinig one year with another, or about two pounds from each plant set out, there would be more than twenty-five pounds of fruit each year in from ten to fourteen pickings. Raspberries may be planted quite successfully either in the autumn or spring.

Red currant jelly and black currant jam are missing from too many farmer's tables, while with a few currant bushes in ia home garden there could b ean abundant supply. The highest yield obtained at Ottawa from six bushes of red currants in one season was seventy-nine pounds, but half of this amount would be a good average yield. Curant bushes should be about six by five feet apart, and they can be planted successfully either in the autumn or spring. There is a marked difference in the hardiness of red currants. Some of the hardiest are Red Dutch, Raby castle, Long Bunch Holland and Red Grape, but these are not so large in fruit as are some not quite so hardy, such as Red Grape, Cross, Perfection and Pomona. The largest-fruiting varieties such as Fay Prolific, Cherry and Comet are only suited for the warmer parts of Cnaada. Among black currants the Boskoop Giant has very large fruit and is of good quality, but heavier bearers with good-sized fruits are Magnus and Climax.

Gooseberries are very productive, yielding about as much as red currants, and a very few bushes will supply the family needs. One of the most productive at Ottawa is a new variety originated there called Mabel, six bushes of which yielded three hundred and one pounds in five years. Gooseberry bushes should be planted about the same distance apart as currants though they may be a foot closer in the rows. Gooseberries can be planted successfully either in the autumn or spring . Downing and Red Jacket or Jesselyn are two of the best varieties in Eastern Canada. On the prairies Houghton is the most reliable; and in British Columbia, Oregon Champion.

The second brood of the currant worm, which strips the leaves from the red currants and gooseberries, may not have gone when these notes appear. For the second brood, which usually apears when the fruit is ripening, white hellebore in the proportion of 1 ounce to 2 galons of water may be used without danger to human beings and it will kill the worms. If bushes are no tprotected from the currant worm they will be weakened, the succeeding crop will not be so good and the fruit may be scalded by the sun. All the small fruits mentioned require abundance eof manure if they are to do their best.—W. T. Macoun, Dominion Horticulturist.

HOW TO DESTROY APHIS OR PLANT LICE

What is the simplest method of exterminating the little green bugs or lice on plants, especially house plants? Where plants are small in seed bed and can be tightly covered can formaldehyde be used?

Ans.—Tobacco water or tobacco extract, diluted in accordance with directions, controls green fly or aphis. This is the florist's remedy. Kerosene emulsion, tobacco fumigation, dry snuff or Persian insect powder are other remedies. Formaldehyde is not used for this purpose. The common decoction of tobacco is prepared by boiling stems or dust thoroughly; then strain and dilnte until the decoction contains two gallons of water to one pound tobacco. All seedsmen sell commercial tobacco extracts.

THE FOUNDATION OF THE FLOCK

In the selection of sheep to commence sheep raising, the selection should be made from some of the improved breeds. They will, of course, cose more than the degenerate natives, but surely will be more profitable in the end, if not immediately. I advise those who intend to commence sheep raising to buy a few at first ,and only the best that are obtainable, though the price be threefold the price of ordinary sheep. An intelligent breeder will seldom allow you to pick his flock, but there are breeders who from increasing age, failing health, or some other cause, are quitting the business, and have clearing out sales, where the buyer can get the best by paying a good price. Where the sales are by auction, you can get your pick by outbidding your contestants.

The reason why the improved breeds are best is because they have obtained the ability of putting on more flesh, and making a faster growth from the same amount of food than the unimproved. The unimproved sheep (like Pharoah's lean kine) can devour everything in their way, anad "still be as ill-favored as at the beginning."

Having obtained some fine sheep for the foundation of his flock, the shepherd must not think his work is done, and that he can lie in bed in the morning and take his ease. The same painstaking that brought the sheep to their high state of excellence must be continued in order to keep the flock up to the present high standard.

In choosing sheep for the foundation of the flock, the quality and weight of the fleece should of course be regarded; but aside from this, the properties most desirable are size, early maturity, constitutional hardiness, disposition to fatten easily, and lightness of offal. In regard to size, it is a disputed point whether the largest breeds, like the Lincolns, do not consume more feed in proportion to their size than the smaller breeds. Some large men eat no more than men of ordinary size, and some eat more than others.

The result of an experiment made in England by Dr. Parry, as stated by himself, was as follows: "By breeding small sheep instead of large ones, on his place, he was enabled on the same area to increase the number of his sheep from 660 to 890, and increase his profits from $2250 to $3620."

One experiment is not enough to establish a fact, and the general opinion among breeders is that large animals are the most profitable. At all events, they sell the best. It has been found that the very heaviest sheep are not so well suited to elevated, precipitous mountain ranges.

The lungs of animals are of the utmost importance, as upon their size and soundness the health and the strength of the ainmal chiefly depend. The size and strength of the lungs (as indicated by the size anad breadth of the chest) is a great point to be regarded. The head should be small, as by this the birth of the lambs is facilitated. Not only this, but a big head on a sheep, hog or steer is not regarded with favor by the butcher, as it causes more loss by greatr weight of offal. The length of the neck should be in proportion to the height of the sheep, not only because it conforms to the law of symmetry and beauty, but so the sheep may obtain its feed from the ground with ease and comfort.

Most breeeers are agreed that the bones should be small in proportion to the weight of the flesh and wool. Extremes in breding for smallness of bones should be avoided. Bones may be too small to properly sustain the weight of the flesh and wool. My father had two fat hogs that broke their legs in the pen when trying to get up. Evidently they had been bred for smallness of bone a little too long.

For the foundation of the flock, the flockmaster should take pains to secure purebred ewes of the breed he desires to keep, and not more than three years old. They should be in fair condition when the ram is placed with them. Five months is the period of gestation, and to have lambs dropped about the first of February, the connection should take place about the first of September. It is less trouble to have lambs weaned in May, after the weather has become fine, but the early lamb weaned in February or March (sometimes called "hothouse lambs") are in great demand and are much more profitable than those weaned later.

Thomas Hale gives this direction for choosing a ram: "Let him be young, wholesome and well shaped, his wool clean and well grown, the skin underneath of the same color; let the body be large, his forehead broad, round and rising; his eyes be large, and of a cheerful aspect, his nostrils straight and short."

When about 15 months old, a sheep has two broad teeth in front; at 24 to 27 months the have four; at 36 to 39, six; at 50 to 57 months, eight; after the fifth year, a sheep is known as to age by a full mouth of 32 teeth in all—the same number as cows and steeers have. In a lower jaw there are eight incisors, or cutting teeth—the precise number existing in the mouths of mankind; but in mankind half are in the upper and half in the lower jaw, and teeth bite against teeth; whereas in sheep, the teeth in the lower jaw bite against a tough, fleshy pad or roof of the mouth.—J. W. Ingham.

CONTROLLING ABORTION IN COWS

Are there any methods that can be adopted as precautionary measures in preventing or controlling abortion in cows? For the last few years I have had it to a considerable extent in my herd.—A. B.

Reply.—The proper disposal or handling of the body excretions is the most important thing in controlling abortion disease. A cow showing a discharge from the genital tract should always be isolated from the herd in a speecially arranged stall. All bedding should be removed from her stall and burned or buried after being covered with quicklime. The floor of the stall should be sprayed or sprinkled with a strong solution of an antiseptic or covered with lime.

The foetus and foetal membranes should be burned or buried and covered with quicklime. In case an animal aborts before she has been isolated from the remainder of the herd, the floor and gutter should be cleaned and disinfected, but the odor from most disinfectants are objectionable to the dairymen. The most reliable disinfectant, minus the odor, is copper sulphate. Six ounces to each gallon of water will make an efficient solution. It should be used with precaution in case iron stanchions are used as it wiill corrode iron. The quarantine stall, previously mentioned, should be cleaned from top to bottom, and thoroughly disinfected each time after the patient has been removed. However, the patient should be scrubbed with a one and one-half per cent, water solution of cresol or coal tar disinfectant just before leaving the stall. This will prevent the infection on the outside of the body from spreading to other cattle.

Aborting animals should not be bred until all discharge has ceased and they show signs of a normal oestrum. The bull should be irrigated before and after service with a one-half per cent, water solution of compound of cresol. The tuft of long hair from the opening of the sheath should be clipped, and then insert a soft rubber tube with a funnel attached to one end. The foreskin should be held with the hand, thus preventing the immediate escape of the fluid. The hair of the belly and inner sides of the thighs should be sponged with a 1 or 1½ per cent. water solution of the cresolis compound or a reliable antiseptic. Every precaution should be taken against using too strong an antiseptic for douching either the cow or bull. Bad results have followed their use.

To make a ½ per cent. water solution add 5 drams of antiseptisc to one gallon of water.

To make a ¾ per cent. water solution add 7½ drams of antiseptic to one gallon of water.

To make a one per cent. water solution add one ounce and 2 drams of anatiseptic to one gallon of water.

To make a 1½ per cent. water solution add 3 ounces and 1 dram of antiseptic to one gallon of water.

To insure accuracy, a graduated flask should be purchased and used for measuring the antiseptic.

PARASITES

Parasitic diseases are most common in low-lying marshy land, and they are, next to dogs, the cause of the greatest loss among sheep. Parasite are of two classes, external and internal. The external ones are lice, ticks and scabmite, and none of these should be in existence at all, as they can be stamped out by dipping. The carlessness of a few farmers in this matter is enough to keep the whole sheep industry in a continual war against external parasites. There are a number of commercial dips on the market and a number that can be home-made;; all are good when properly used. In coal tar dips it has been found much more effective and beneficial to the wool if soap is added. Lime and sulphur dips had a tendency to spoil the texture of the wool. The best time to dip is immediately after shearing, but dipping should be done every time it is necessary, either as a preventative or as a cure. If the fall dipping is done, a warm day should be chosen, or a warm place to herd them in till they are thoroughly dry.

The purchase of rams is one of the chief causes of spreading the diseases arising from worms. Certain dis-

tricts are badly affected and lung worm disease is imported by buying sheep from these districts; and once a pasture is affected, it is impossible to clear it from the pest. Lung worms show their first signs in the lambs, by their commencing to cough. It is not found in lambs up to six or seven months old, but reaches its height at nine months old. Farmers who go in for selling fat lambs should get them on the market before they are nine months old. Weaning time is the period at which lambs are most liable to be affected, and for a cure, the injection of turpentine into the windpipe is advocated.

The nodular worm confines its work to the small intestines, and the chief cause that gives rise to this form of parasitic disease is feeding on low, swampy land. Feeding of salt to sheep has a great effect in ridding them of parasites.

For stomach worms the best agent is the oil of turpentine, and half an ounce is about the average dose for a sheep. Ground blue stone has also proved its beneficial effects with stomach worms; a teaspoonful for every sheep, mixed with the feed, is the quantity sufficient to free affected animals of stomach worms.

Foot rot can largely be controlled by dipping, but for its prevention the hoofs of the flock should be examined and any overgrown or ingrowing hoof that collects dirt should be pared off. Restrictive measures should be adopted to prevent sheep affected with lip and leg ulceration from being taken from one place to another, as it is very contagious. Every sheep breeders' association should be acquainted with infected districts and no animals should be purchased from such a district.

CATTLE BLOATING DANGEROUS

With the approach of the season at which bloating of cattle frequently occurs, the principal cause of the trouble and means by which it may be avoided will be of interest to our readers.

Many a cow has come to an untimely end because she became dissatisfied with the scanty feed to be gathered from the closely crop-fed pasture, broke down the fence that surrounded a field containing a more luxuriant growth, and stuffed herself with the luscious, stolen greens, until he lost all desire for even another mouthful.

Soon her troubles begin. Fermentation develops in the mass of corn or clover, and gas forms that fills the first stomach of the cow to its utmost capacity.

How Fermentation Causes Death

The danger to the animal from acute bloating is not that the distended stomach may rupture, for such an accident is almost unknown. The pressure of the gas-distended stomach, however, exerts a dangerous pressure upon the heart and lungs, with the result that animals dying from acute bloating usually die of strangulation through inability to breathe with their compressed lung tissue.

The stock owner should guard against the bloating of his cattle by every precaution at his command. Clover or other green vegetation, if eaten when wet by dew or rain, seem to be especially liable to ferment before leaving the first stomach of the animal that has fed upon them. Eating excessive amounts middlings or corn meal will also cause bloating. It also occurs in cattle as a result of becoming choked. The principal cause, however, is overheating succulent green forage, such as clover, or green corn or cabbage.

Change Feeed Gradually

To prevent bloating in cattle, the animals should be shifted, by easy stages, from dry or scanty feed to abundant and luxuriantly growing fodder. They may be allowed to feed from the good forage efor only three-quarters of an hour on the first day they are given access to such grazing. A full hour may be allowed on the second day, and by continued slow steps and gradually lengthened stay in the tempting feed, the danger of loss from bloating will be largely overcome.

But in case the first evidence of a too protracted stay in the heavy growth of forage should be that the owner notices one of his animals with sides distended, and perhaps even lifted above the level of the backbone, he must act quicky. Removal of the gas from the paunch will quickly bring relief. If a veterinarian is within reach he should be summoned at once. If no surgeon is available the owner should immediately attempt to bring relief to his animal.

Trocar and Method of Use

Many cattle owners keep a trocar and canula constantly on hand and thoroughly understand its use. The trocar is a sharp-pointed rod provided with a metallic sheath or canula which leaves the point of the trocar exposed. The spot to be selected for inserting the trocar is a point equally distant from the last rib, the hip bone, and the lateral bony projections from the spine in the region of the loins. Here a small cut about three-fourth of an inch long should be made through the skin with a small knife, and then the trocar witih canula attached may be pushed through the cut into the paunch. The trocar is then removed, allowing the gas to escape through the canula. The canula should be retained in place so long as any gas escapes through it. Sometimes several hours are necessary, and the canula should be firmly tied in place. An attendant should remain near the animal ,if possible, so long as the canula is in the paunch.

Medicines That Relieve Bloating

If the animal is not distressed and the bloating and swelling of the body is not great, or when the alarming conditions have been removed by the use o fthe trocar, it is best to resort to internal medicine to allay the formation of gas. Two ounces of aromatic spirits of ammonia in 2 quarts of cold water should be given every half hour, or half an ounce of chloride of lime dissolved in a pint of tepid water may be given every half hour until the pressure of the bloating has been removed. A dose of purgative medicine is usually beneficial after the bloating has disappeared. For this purpose 1 pound of Glauaber's salts will usually prove effective.

Care should be used in the administration of fluid medicines. Take time. Do not hold the cow's head too high. Keeping the aniimal's head raised so that her nose is slightly higher than the level of her face will allow her to swallow without interference.

CARE OF PIGS BEFORE WEANING

The fattest and cheapest gains by pigs are made before weaning time, so ordinarily it will pay to keep the small pig growing as rapidly as possible. The sow should, of course, get some good milk-producing feed, and she should be fed to her full capacity as soon as the pigs are old enough to take all the milk she will give. It will not pay to limit the feed at this time, according to L. A. Weaver of the Missouri University College of Agriculture, since the pigs make the most economical gains from feed fed through the sow. When the pigs are about a month old, they will be able to use more feed than that obtained from the sow even though the sow is properly fed and a good milker.

As soon as the pigs eat, which is usually at four or five weeks of age, they should be fed separately from their dam. They should have access to a small pen where the sow cannot go to receive their feed. Skimmilk fed in a shallow pan is very good for them. The pigs may also be taught to run into the creep for feed. As soon as they begin to eat well, a slop made of milk, some shorts, a little bran, and some linseed-oil meal or tankage, fed along with the chopped oats, will make a ration which, with proper exercise, will prevent thumps or scours.

A good ration for young pigs is made up of four parts by weight of ground oats and barley, four parts of shorts, one part of bran, and one part of tankage. As the pigs become older the grain may be gradually increased until the amount has been doubled.

In addition to proper feed, however, the pigs must have plenty of sunshine and exercise. These things cost little to supply and are absolutely necessary for best results.

LIVE STOCK FARMING

One of the advantages of live stock farming is that it furnishes employment throughout the entire year. With grain farming the chief demand for labor is during the rush periods of preparing the land, planting, cultivating and harvesting the crops. It is then that labor is highest priced and usually hardest to secure. When work can be guaranteed throughout the winter, it usually possible to secure help that is sufficient and reliable, and especially so if a good tenant house can be provided. A married man who is more or less settled makes the best sort of help for the farmer who desires a steady hand.

THE SCARCITY OF FEED

The scarcity and high price of feed makes Herbageum a necessity in economical feeding, either of horses, cows, calves, sheep, pigs or poultry. By its use all classes of feed are more easily and thoroughly assimilated. Waste is avoided and better returns secured from the same amount and quality of feed. As good calves can be raised on skim or separated milk with as on whole new milk without it. And fresh whey seasoned with it is fine for hogs. Heavier weights and sweeter and firmer pork and better lard are secured when Herbageum is given regularly. Make your own calf meal. Write us for the formula. Herbageum at present is only 25c per lb. but would be economical at 40c per lb.

DAIRYING

HYDRATED LIME SOLUTION AN EFFECTIVE GERM DESTROYER FOR THE MILKING MACHINE

The milking machine, like any other piece of machinery, must be kept in good condition to do its best work. Just recently I talked with a man who was milking about 40 cows by machine. He said: "The first month I had the machine it worked fine, but it kept milking slower and slower, so I increased the speed and it seemed to help for a few days. Then it got to milking slow again. Now I have the speed of it twice as great as is recommended in the directons, and I mlk them out in a hurry." This is a big, strong man who believes in doing everything by might. No one can milk a cow by machine by determination and strength. I did not have an opportunity to find out what the trouble in this instance was, but I believe I could come near telling what might be the trouble, writes Prof. C. Larsen of the South Dakota College of Agriculture in Hoard's Dairyman.

Vacuum Should be Steady

This particular machine was not of the pipe-line type. The vacuum or suction was created in a small pump located on the stanchion frame in front of the cows. Probably the ring on the end of the plunger had become dry, stiff, and even worn. In some climates, dry and high altitudes, leather and rubber will dry out much quicker than in lower and more moist climate. In this condition it was not able to produce the sufficient and proper amount of suction.

Maybe the machine milked the easy cows too fast at first, and the excess of milk went up into the pumps. This would happen only with the easy milkers. The effect of it, however, would be equally bad if it happened every milking time with one or two cows in the herd. The leather or rubber rings on the plunger would become very soft, greasy, and loose of form. This would also cause a lack of vacuum.

Maybe he forgot to shut the pit cock in the end of the pump. This would release considerable of the vacuum. In faet, this draincock is there for drainage, and to be closed when hard milking cows are being milked, and to be opened when easy milking cows are to be milked. This latter prevents the milk from running over into the pump.

Leaky Teat Cups and Rubber Tubes

After the vacuum is generated and produced in exact amount, it must be made to apply on the cows in that force. If it has been determined from numerous experiments that 16 inches is the proper amount of vacuum for milking, then 16 inches should be made effective. To generate 16 inches and closely watch that the indicator stays on that mark during the milking time, and then allow 3 or 4 inches of this suction to get away through leaks, will necessarily make any machine do slow milking or improper milking.

Most of the machines have special rubber rings at the top of the teat cups. These in time will get out of shape and become ineffective. These rings are inexpensive and should be replaced when there is need for it.

Some of the teat cups have an inner sleeve or a complete rubber wall separating the inner part of the teat cup into two complete compartments. At times these rubbers spring a leak. At times these leaks are very small. When the rubber is not stretched, these leaks can scarcely be noticed. They are similar to a puncture in an automobile tubing, difficult to find.

Such leaks may interfere with rapidity of milking and with some machines they may interfere with the proper balance between the two sides of the rubber wall.

The rubber tubing leading from the vacuum pipes to the milking pail or machine may also leak. Likewise the rubber tubes leading from the pail to the cow may become leaky. These latter tubes are more likely to be at fault than is the one leading from the vacuum pipe to the pail. The tubes leading from the pail to the cow are not so heavy. They are taken apart from the rest of the machine each day. They are heated and washed twice every day. This, in time, will cause any rubber to weaken. The tube running from the vacuum pipe to the pail is made of heavier material. It does not come in contact with the milk except when the pail is milked too full. It is not subjected to so severe cleaning methods as are the rubber tubes coming in direct contact with the milk.

The Pulsator Should be Watched

It is not an uncommon thing to have a pulsator stop or work with irregularity. The most common cause of this is thick lubricating oil. In the winter and in a cold barn even thin oil will stiffen enough to interfere with the proper working of the pulsator.

After a time the pulsator will "gum up." It should then be taken apart and the hard, accumulated grease should be scraped off and all parts cleaned with kerosene.

The pulsator has minute port holes. These are very small and may easily clog. These, together with all the parts of the pulsator, should be kept clean and in good working condition.

The pulsator is one of the vital operative parts of the machine. It is finely adjusted, and it should be treated accordingly.

The solution is made up to about two per cent. strength. About two pounds of hydrated lime are used for each one hundred pounds of water, and stirred.

The cleaned milking machine parts, teat cups and rubber tubing are kept in this lime solution between usages. The pails are cleaned and handled exactly as are any of the other milk pails and cans.

The above method and disinfectant are not the only ways in which the machines can be kept in a good sanitary condition, but it is a good way. Anyone who already is using some other disinfectant and who is already having a handy an dsuccessful way of keeping the machine sanitary had probably better not change.

Undoubtedly some will say this is a lot of work to go through with twice a day, but if prepared for it the task is easy. It can be quickly done.

For the production of certified milk it is necessary to thus take the machine apart and clean thoroughly after each milking.

In order to keep the bacterial count down below 10,000 per c. c. it is also necessary to steam or scald the pails just previous to milking. Otherwise the bacterial count from the milk of the first few cows milked will run high.

For producing good commercial milk the cleaning in two sets of wash water with brushes is necessary only each morning, and not twice each day as described above for the production of certified milk. I have found that in the evening the men are naturally in a hurry. They want to finish the chores as soon as possible. On this account each morning is selected rather than evening.

When this method of cleaning is practiced it is doubly important that the milking machine be well rinsed each evening immediately after milking and before any of the milk has a chance to dry on. Two sets of rinse water should be used. One to remove the excess of milk and then one pail of clean water for final rinsing by attaching the machine to the vacuum pipe.

Keep Vacuum Pipes Sanitary

One would naturally think that the pipes containing the vacuum would not need any attention. But they do. When the machines were first installed in the college dairy barn, this point was overlooked and the quality of milk became bad. The trouble was finally located in the vacuum pipes.

The frequency with which the vacuum pipes need cleaning will depend on whether milk gets into the system or not. If the pails are milked too full, then milk will be drawn over into the vacuum pipes. If this happens every day the pipes should be cleaned every day. They should be cleaned as often as this mistake happens.

Even though no milk is drawn into the vacuum pipes, they will become unsanitary. Vapor or moisture is drawn from the milk pail into the vacuum system. The cold pipes will condense the vapor.

Before starting the milking machine all pipes should be opened and drained, so that none of this condensed

CREONOID

To get more milk from your cows

The cow that is free from flies always gives the biggest milk yield. To keep the cow free from these pests use Creonoid. Spray it in the stall and on the body of the animal.

Creonoid is a low-priced, powerful, non-poisonous creosote product.

Flies, lice, etc., cannot live near it.

If you have any difficulty obtaining Creonoid write to

water with impurities drain into the rubber tubing and even into the pail. This is important.

It is also impossible to prevent dust from getting into the vacuum pipes. This together with the moisture furnish raw material for foulness.

Method of Cleaning Vacuum Pipes

Before the small steam boiler was installed in a room adjacent to the dairy barn, we clean the pipes by pumping two sets of wash water through them. Some water was warmed, and a little washing powder added and stirred until well dissolved.

The vacuum pump was then started, and the prepared warm wash water was pumped through from the extreme end of the vacuum pipe. This water with any dust in the system was drawn into the vacuum storage tank located in the power room. At the bottom the vacuum tank there is a drain where all of it was drained away.

When this set of wash water had done its work well, then we pumped through a pailful of boiling hot water, and drained away from the vacuum storage tank as before. The power is shut off and all drain cocks opened. This leaves the vacuum system clean.

The heat in the pipes absorbed from the hot water will dry the whole inside and leave it in a clean, dry condition.

Since the installation of the small steam boiler, steam alone has been used. All drain cocks and places of attachments are opened. A small hose connects the vacuum pipe and the boiler. The steam is gradually turned on. At first the cold pipes condense the steam. When little more steam is turned on, the water rinses out all dirt particles.

The steaming thoroughly destroys all living organism. It also heats the pipes so they dry well after cleaning. This method of cleaning takes very little time. It is effective and does no harm.

If any milk had been accidentally drawn into the vacuum pipes, then they should be rinsed out with lukewarm water before the steam is turned in.

This cleaning we do regularly once each two weeks whether there is a need for it or not. It takes but a short time, and it is better to do it once too often than it is to run the danger of having the milk infested with abnormal and undesirable germs.

Sanitation Important in Machine Milking

When the question of keeping milking machines in good sanitary condition comes up, then some prospective users think that this is the worst part in connection with mechanical milking. The worry, however, subsides when the customer is told that some certain disinfectant is used, and that by keeping the different parts of the milking machine in this disinfectant solution between milkings no difficulties are encountered. That suggestion is quieting. It is like pouring oil on the troubled waters. However, the cleaning of milking machines should not be faced in that light. The cleaning of milking machines is no different from the cleaning of any other dairy utensil.

One day a prospective farmer came to the college dairy barns. He looked at the various pipes used for conducting the vacuum. He said: "Do all of these pipes belong to the milking machines?" He was informed they did. "I should think it would be an awful job to keep all of those pipes clean. I should think they would get to stinking in this hot weather." He is not the only prospective user of milking machines who magnifies the task of keeping a milking machine in a sanitary condition.

Not Many Parts to Clean

A milking machine can not be kept sanitary alone by soaking the parts in a disinfectant, or is there any need of making a mountain of difficulties over the cleaning of milking machines.

Any person owning enough cows to purchase a milking machine should be reasonably well prepared with cleaning facilities, such as hot water, a good washing compound, and a small container or vat for this purpose. The washing room should also be provided with a vacuum pipe and proper shut-off and attachment.

There are only a few parts to be kept clean and these parts are not difficult to get at.

Steps in Washing

When the milking is completed, the idfferent machines or pails are taken to the wash room. This wash room is equipped with a small five horse power, upright, submerged flue boiler. When purchased it cost $100, and I believe that every dairyman who makes dairying a business at all should have similar facilities for plenty of steam and hot water. In addition it funrishes a place for drying things, it keeps water and pipes from freezing, and it also furnishes a comfortable place for the help to do the cleaning of the separator, pails, etc.

This warm room also has in it a small vat having two compartments, one for hot, clean water to be used for rinsing, and the other for warm water containing the washing powder. A water supply pipe and a steam pipe lead up to the centre of the vat on the wall side.

The machine is first connected up with the vacuum pipe by means of a short pipe of rubber tubing, and the vacuum is turned on. The teat cups are inserted in a pail full of lukewarm water. The tubes are lifted up and down. This together with the vacuum rinses the teat cups and rubber tubing. If this is done at once after milking before the milk has a chance to dry on, then there will be very little milk to wash off by hand and brush. The gulching of the water thus brought about is quite effective.

However, this alone is not enough to keep the milking machine in good sanitary condition. The water in the double vat is then made ready. One compartment is filled with a clean, hot water, and the other compartment is filled with warm water containing some washing powder. The former is used for rinsing and the latter for washing. The temperature of the rinse water should be about 125 degrees F., and that of the wash water about 100 degrees F.

When the rinsing by vacuum is completed, the machine is taken apart and put into the prepared wash water. With the brushes specially provided, the different parts are cleaned, and one by one they are dropped into the other compartment containing the rinse water.

Keep in Disinfectant

From there the parts are put into the disinfectant solution. There is a great deal of difference of opinion as to what kind of a disinfectant to use. At this experiment station practically all of the common ones have been used and they have been tried at the same time comparatively, and bacterial analysis and observations made.

None have been found better than ordinary hydrated lime solution. The lime may be purchased anywhere. It may be had in a convenient package. It costs very little. It is not a poison such as are some of the other common disinfectants. Lime may be kept in a dairy with perfect propriety and safety. Lime does not cause odors in the milk room, or in the barn that will endanger the flavor of the milk. Lime is an effective germ destroyer if used properly. Lime solution does not affect the rubber and metal parts of the machines. Lime has a cleansing effect that can not be had from some of the other substances. It is deoderizer, as well as a germ destroyer.

Adaptability

THE reliability and economy of the ALPHA engine are well known, but the ALPHA offers another striking advantage—that of *adaptability*.

Trade Mark

Besides being made in eleven sizes, ranging from 2 to 28 H. P., the ALPHA has all kinds of optional features to enable every gas engine buyer to get just the size, type and equipment best adapted for his needs.

The ALPHA can be *adapted* equally well to gasoline, kerosene, alcohol and gas—whatever fuel is best available.

Send for ALPHA catalogue, which shows how perfectly *adaptable* the ALPHA engine is—and see nearest ALPHA agent, who will give you the benefit of his gas engine experience.

If you don't know who handles the ALPHA in your vicinity, write nearest sales headquarters for his name.

CALF SCOURS

For ordinary calf scours the following prescription has been often recommended as effective: Mix 1 ounce of bismuth subnitrate, ½ ounce of salol, and 3 ounces of bicarbonate of soda and give one tablespoonful three or fou rtimes a day until the calf has recovered. Overfeeding and the use of insanitary feeding vessels are two causes of scours. Regular feeding periods should be observed and the milk should always be at the proper temperature. Make changes in feed gradually and do not overfeed. Keep the calves in a clean pan.

Shorthorns

The Breed For You

Shorthorn steers hold the high-price record for a carload on the open market in Canada. They also hold the high-price record for carlots of heavy steers, yearlings and feeders on the American open markets. They are money makers.

THE HORSE

SORE SHOULDERS IN HORSES A COMMON COMPLAINT OF THE DRAFT ANIMALS ON HOT DAYS

This is a season that is exceptionally hard on horses. Letters from readers of Farm Journals reveal the information that many horses are dying from heat and exhaustion. This is more often found to be the case where a young colt is making his first appearance in the team as a worker. The most critical period in the life of every horse is the first few months at work, and in these days of high prices every effort should be made to keep farm horses fit for work every day.

Hardening the Skin of the Shoulder

Of all the ailments that subtract from a horse's usefulness none is of more importance than sore shoulders and necks. Unfortunately this is a part of the care of a horse that does not get the attention it deserves, either by properly fitting the collars or caring for the animal itself. When a colt first begins work the muscles of the shoulders are soft and the skin tender; the collar bed is narrow and sloping, not at all like a place fitted to receive the average collar. After the shoulders become sore they will never again regain their normal resistance to collar wear.

The importance of properly hardening the shoulders of the young colt cannot be over-estimated. Horses' shoulders will of course harden with age, but only if they are well kept. Shoulder sores, like all other sores, heal by the formation of scar tissue, which does not have vitality of normal muscle tissue. The training of a horse means the fitting of him for work and there can be no economical motive power without proper attention to the hardening process of the skin of the shoulder. Start the animal to work slowly, and bathe the shoulders at noon and night with a strong cold salt or alum solution.

Fitting the Collar

The fitting of a collar is another item in the training of the horse to work that does not get its due consideration by all horsemen. The practice of hitching up a horse with the first collar that comes to hand, will prove ruinous to the horse's shoulders. The fitting of a collar like the fitting of a shoe, requires not only the correct size, but the correct shape or style. If you had to wear every day, the first pair of boots that was thrown to you each morning, how would you find your feet after a week? Red, raw flesh, would have taken the place of hot broken blisters, and the operation of fitting shoes on your feet, perhaps a size or two small, by some unsympathetic individual would be greatly resented.

Some horses require long, narrow collars, while others require short, wide ones. Most horses are fitted best by a collar that narrows a few inches below the middle and widens at the top. This principle alone will in many cases prevent sore necks. When the collar is properly fitted there should be just room enough to slide the fingers between the collar and side of the neck. Below the neck there should be the space of an inch or more. A horse's collar should not be changed or worked on other horses, even though another have shoulders of the same size; when a collar becomes shaped to a horse's shoulders it is very desirable that it maintain that shape.

Keep Collar in Working Order

The practice of allowing the horse to stand during the noontide rest in very warm weather with all his harness on is also against his full utility at work. The excuse is put up that there is no time to unharness the animal, but time will be practically lost in the usefulness of a horse during the season, when not given the grooming and cleaning attention at noon, and this cannot be done with the harness on. Throwing the collar down in any odd corner, with its top unfastened will put the collar entirely out of shape. Instead of keeping the collar inside the barn at noon it should be cleaned on the pad side and dried in the sun. Never scrape the face of the collar with a knife or curry-comb; it will be roughened by such treatment. Then fasten it at the top and hang it up so that it will not lose its shape. Whenever the collar begins to get dry and hard, it should have an application of neat's foot oil—not too much at a time, just enough to keep the leather soft and pliable. This will lengthen the life of the collar as well as make it more comfortable for the horse. Whenever the face of the collar becomes hard it should be softened by pounding with a round stick about two inches in diameter. As a general rule, the cheapest collar, from the standpoint of the horse and from the standpoint of length of wear, is the best that money can buy. Buying cheap collars is poor economy.

Treatment of Sore Shoulders

Dr. Wilson, of the Pennsylvania State College, gives some very practical suggestions on the treatment of sore shoulders and he divides them into two distinct types as follows:—

"The type of sore accompanied by a large amount of swelling is due to the rupture of a blood vessel. The only treatment is to have a competent veterinarian darin the swelling and give the horse sufficient rest to allow healing. By far the most common form of sore shoulder is that produced simply by the collar wearing through the skin. More than 90 per cent. of this form of shoulder sore can be prevented if the shoulders are properly hardened, if the collars fit properly, and if the proper medicinal treatment is applied. For prevention and treatment nothing is quite equal to tincture of chloride of iron. As soon as it is noticed that the hair is beginning to wear off the shoulder or that the skin is becoming red, special attention should be paid to the fit of the collar and twice a day the worn area of the shoulder should be painted with tincture of chloride of iron. This has the

Cletrac
TANK-TYPE TRACTOR
Makes You Independent of the Hired Outfit
With a Cletrac Tank-type Tractor you can be independent of the hired power outfit.
All through the harvest you'll save time with a Cletrac. Pulls an 8-foot binder and reaps 25 acres a day. There's time saved for you! Horses saved! Works on the hottest day, as long as you like, without faltering.
Load up two or three wagons with grain and the Cletrac will haul them to the barn for threshing. Then hitch it to the threshing outfit. You'll be astonished at how soon you can finish up the harvest.
And when silo-filling time comes, the Cletrac will repeat. All the year round—hauling logs and stones, sawing wood, mixing cement, hauling wagons, plowing, discing, harrowing, seeding—the little giant Cletrac Tank-type Tractor buckles down to work and saves you money.
Learn *all* the good points of the Cletrac. Talk to the Cletrac dealer. Ask him or write us for our interesting booklet, "Our Owners Say." It tells the Cletrac story *in the users' words.*
JOHN LUMSDEN
LUMBER MANUFACTURER
Ottawa, Ont.
Beach Molors, Limited, Ottawa, Ont.
Gentlemen,—I have now had the Cletrac Tractor I purchased from you in use over a month, and want to take this means of advising you that the performance of it wherever used has been entirely satisfactory—in fact it has surpassed my highest expectations.
Besides pulling a three-bottom 12-inch Cockshutt plow in old sod full of Scotch grass, I have run my 30-inch threshing machine with blower, and also filled my silos, using a No. 5 Blizzard cutter.
There seems to be so many things that can be done with this machine, so much more satisfactory and economical than with horses, that I am sure it will fill a long-felt want for the farmer.
Wishing you continued success, I remain, yours truly,
(Signed) John Lumsden.
The Cleveland Tractor Co. of Canada, Limited
Windsor, Ontario

effect of hardening or tanning the skin and prevents further wear. While the horse is at work salves should be avoided in the treatment, as they tend to soften the skin and wear takes place faster. If the horse is to be laid off, then salves are indicated in the place of the tincture of chloride of iron. But as long as the horse is in the collar nothing is equal to the tincture of chloride of iron. Tumor-like callouses which often form on improperly cared-for shoulders should be removed surgically by a competent veterinarian. No other treatment will effect a permanent cure."

Fitting the Hitch

A horse that has worked for some time will be subject to considerable shrinkage of the shoulders, which often necessitates a smaller collar. This fact necessitates careful attention. When a horse arrives in spring time in good and fit condition and full of flesh, it is certain that the collar he wears will need readjustment from time to time. More horses are working in collars too large than too small. The hames should be buckled tightly and so adjusted to fit the collar that the traces will pull from the centre of the shoulder bed. The hitch should be neither too high nor too low. A high hitch will cause sores on the point of the shoulder, a low hitch will cause sore necks. The hitch should be at a height that will cause the traces to pull at right angles to the collar bed. For this reason it is undesirable to work a tall and short horse in the same team unless the hitch can be properly adjusted to each horse.

YOUNG COLT AT WEANING REQUIRES BREEDER'S SPECIAL CARE AND MANAGEMENT

Take another look at that colt that has been well nurtured by its mother. It is a perfect model in form, a picture of health and full of fire and spirit. I never see one but I think of its future and the fate that awaits it. It is here that domestication breaks down and nine-tenths of all the diseases and short comings of horse flesh originates. What a different looking class of horses, than those seen in many districts today, would be found if the fateful period between weaning and mature growth was given more consideration. No horse will arrive at mature years endowed with full power, health and energy if the breeder has lost sight of the ideal as given him in the foalhood picture.

Every colt deserves a good start. It is necessary if the youngster is to be made into the best and most profitable animal. Pushing colts from outset is one of the biggest factors that have contributed to the success of growing good horses. It is only the men who study colt-weaning as a special subject who have mature draft horses worth the name or worth the rearing.

Preparing Colt for Weaning

A foal will probably take its first mouthful of grain from its mother's feed box. So soon as a foal learns what grain is, it needs a feed-box, set rather low at a place convenient for it, and at the same time out of reach of other animals. There is no more interesting work around the farm than that of preparing the colt for weaning time. There is probably no time in the life of a horse when such profitable returns are made from feed as when it is fed to foals.

When the time arrives for complete separation of colt and mother there will be no setback if the colt has been accustomed to hand feeding during the preparatory period. On the other hand, if the foal has to learn to eat. Weaning, properly described, is an act of preparation for the time it has to do without its mother. The sensitive animal loves to be fondled and fed and there is no better way of gaining its confidence than through its stomach. A little brown sugar fed to them by hand or sprinkled over their grain feed is a good first step in the act of preparing them for the weaning. After being deprived of its mother, it will loose flesh and constitutional vigor while getting used to the new conditions and treatment. For a colt that has not been well nourished by the mother, it is a good plan to teach it to drink skimmed milk, and its continuance after weaning will prove exceptionally beneficial. Clean, sound oats well ground constitute the best of all grains for young weanlings. If to this a little oil meal is added, about half a pint a day, good gains will be made in spite of cold weather. Feed liberally; there is far more danger and permanent injury from under feeding than from over feeding. Watch the colt closely and find out the quantity it can use with safety and feed up to it.

About five or six months is long enough for most foals to nurse. By that time if they have learned to eat grain they can be weaned without a setback. If weaned while there is still a month or two of grazing ahead during the fall, the transition from soft to dry feed is made very gradually.

Winter Housing

Besides the feeding there is the housing and general care of the colt that bulks largely in the welfare and growth as well as its future health and usefulness. Do not let the little fellow stand out in the cold wet weather, neither in the field in the fall nor in the yard in winter time. Another practice that is entirely against the chances of keeping the colt in growing vigor and spirit is tying hm up during thei winter months in some out of the way dark corner of the barn, where he becomes an exile from any domesticating influence, and where feeding facilities are lacking. Choose a light, airy place for the young colt, where he can enjoy winter life with summer freedom. Make feeding horses one of your winter hobbies; there is plenty of time in which to engage in the work. When you are busy in summer the colt can look after himself if given the chance of a good pasture. Remember that good pastures in summer will never make up for what has been lost in winter. Roots, either turnips or mangels, supply the place of the summer succulent grass and should be given regularly every day. Roots have a cooling tendency, contracting the heating effects of concentrated feeds. Many colts are spoiled through want of sufficient quantity of water. They are offered it perhaps the usual regulation number of times, but many colts will not drink ice cold water unless they are forced by excessive thirst. Water should be before them at all times in the stall. A colt cannot be kept growing in winter unless this precaution is taken. Timothy hay is not conducive to growth, and a portion of the best clover, alfalfa, or mixed hay should be saved for the use of the colt.

Winter Exercise

Liberal feeding and abundance of exercise go hand in hand in colt raising, but it is a mistake to think that you have to give them exercise whatever the weather may be. It will pay to keep them in when cold winds blow, when sleet or rain is falling, or when it is at zero weather. The argument that colts are reared in the west, out all winter does not fit the conditions of the colt that has been born and reared in Eastern Canada. The air in Western Canada is more rare and dry, and the colt and its mother run free all the time. There is not a foot or two of wet snow lying on the farm for four or five months of the year, as it does here in the East.

In no other way can colts be ruined so surely and so permanently as by close confinement. Each day from two to four hours should be spent in the open air, according to the conditions of the weather. Never let them out with empty stomachs, especially in zero weather. To send newly weaned colts to rustle for an existence in a yard or box stall along with yearlings or two-year-olds, which is often their fate, is to court failure at the start. They should get special attention alone or with companions of the same age and experience. They are naturally sensitive animals, and when left out in the cold or are herded along with older horses they naturally pine and lose heart. Stomach troubles that come in after life are generally due to neglect during the first winter's attention and feeding. To retain their spirit and health should be the aim of ever ybreeder, and the most vital period of their life, where these can be irreparably crushed, is at weaning time and the two succeeding years.

Horsemen Attention !

Dr. J. Woodbury's Horse Liniment and Dr. J. Woodbury's Condition Powders will save and preserve the life of your horses. Their use will cure and prevent the disease common to horses, such as Cough, Colds, Distemper, Spavins, Pinkeye, Splints, Curbs, Enlargements, Cracked Hoof, Kidney Trouble, Fevers, Cuts, Sores and will remove bunches of all kinds.

BEFORE USING

Why have a sick or lame horse, when you can get a reliable and warranted remedy? The leading horsement of the Dominion endorse Dr. J. Woodbury's Horse Liniment.

FOR SALE ALL DEALERS

PRICE 35 CENTS

Do you know that "Dr. J. Woodbury's Horse Liniment" is endorsed by all the leading horsemen of the Dominion. Save and preserve the life of your horses by its use. It will cure and prevent disease common among horses.

POULTRY.

NESTING EQUIPMENT FOR HENS

Suitable nesting equipment is essential for the successful management of laying hens. It should be planned to minimize the labor required in gathering eggs, in keeping nests clean and in supplying suitable nesting material. It is also important that the nests be made attractive and satisfactory to the hens.

The tendency of hens to lay their eggs on the poultry house floor, in the poultry ward or in "stolen" nests causes serious losses to poultry keepers. It increases the labor of finding and gathering the eggs. it causes the entire loss of many eggs and a deterioration in the quality of many others, and not infrequently it becomes the direct cause of fowls acquiring the vicious egg eating habit.

fI a sufficient number of nests is not provided to accommodate all the hens that wish to lay at any one time there are but three alternatives for the hen. She may appropriate a nest already occupied, lay somewhere else than in one of the nests provided, or wait until some other hen leaves the nest. The fact that most hens closely follow a definite time schedule in laying makes it appear doubtful whether it is possible for hens to long delay the time of laying, even if they desired to do so.

Observation made in securing data on this matter support the idea that hens cannot be relied upon to adopt a watchful waiting policy in this regard. To prevent hens from laying on the floor, in the poultry yard or in "stolen nests," and to prevent the broken eggs often resulting when more than one hen attempts to occupy one nest at the same time, it is necessary to have as many nests as there are likely to be hens wishing to lay at one time.

Our data show that for each egg produced by a flock, one nest is occupied for an average of two hours, and that during the months when egg production is heaviest we may often expect at least a third of the laying hens wishing to occupy the nests during the same two hours of the day. As a flock of good layers will not infrequently produce as many as three eggs for each four hens in the flock, it would seem that one nest for each four or five hens would not be more than a safe number to provide, and in the case of flocks of less than 100 fowls, where chance is an important factor there should be even more nests.

Type and Location of Nests

The nests and their location in the poultry house should be planned with reference to convenience in gatherinig the eggs and keeping the nests clean and free from vermin, as well as making them attractive to the hens.

One of the commonest locations for the nest is beneath the perches. This necessitates the use of a good tight dropping board to prevent the nests from becoming contaminated. When such a dropping board is used there are some disadvantages in locating the nests under it. The nests and roosts are the most common places to become infected with mites and the use of these two classes of fixtures together may tend to increase the difficulty of exterminating this pest.

If there are more than two or three roosts, the use of nests under the dropping board cuts off access to the wide floor space to the rear, and because of the seclusion afforded increases the tendency of the hens to lay on the floor, where the eggs are difficult to gather. On the other hand, this location permits the use of cheaper and more simply constructed nests than is reuireqd elsewhere, and most readily affords the desirable seclusion for the nests.

Recently a number of poultry keepers have been using and recommending a nesting box without partitions in it. Partitions, however, make each nest more secluded, and hold the nesting material in shape once the nest has been made. The writer has observed that the hens prefer to adopt a nest in which the nesting material has already been moulded into shape, rather than to arrange the nesting material in shape themselves.

How Often Should Eggs Be Gathered?

One of the most important measures that can be taken to prevent deterioration in the quality of eggs is to keep them cool. The development of the chick embryo of fertile eggs, the breaking down of the albumen, weakening of the yolk membrane and the evaporation of water from both fertile and infertile eggs constitute the most serious losses in egg deterioration and these all take place most rapidly at warm temperatures.

Both fertile and infertile eggs will suffer a greater deterioration in quality each hour they are held at a temperature equivalent to that of an occupied hen's nest, than they will each day when kept under favorable storage conditions. With most of the eggs being laid in the forenoon, but with a significant number of hens laying in the afternoon and spending an average of two hours each on the nest, considerable deterioration of a large per cent. of the eggs will be prevented by gathering them at noon and again during the evening.

If care is taken not to disturb the hens more than necessary the nests will be made even more attractive to the remaining hens as has been shown by the observcations reported elsewhere in this buletin. Gathering the eggs twice each day is, of course, more important during warm weather but it also helps to keep the eggs clean when the hens are on range during wet, mudy weather.

The ideal conditions for maintaining the hatching quality of eggs held for incubation seem to be somewhat different than those required for preserving the quality of eggs considered from the standpoint of their value for human food. In maintaining the hatching quality of eggs it is necessary to provide conditions that will maintain the life and vigor of the germ as well as the food material that has been put in the egg to nourish the embryo through the period of incubation.

It is interesting to note in this connection that the hatching quality of eggs is more effectively maintained if they are warmed up each day so that they are subjected to the same temperature conditions that they receive when they are laid in the stolen nest. It has been found that by placing under hens for sixty minutes each day the eggs that were being held for some time for incubation, the number of vigorous chicks hatched was increased 10 per cent. What would be the effect of holding the eggs at such a temperature for a longer period each day has not to the writer's knowledge, been determined, but since the hen using a stolen nest probably spends as much time on the nest as when aying under the conditions of the tests reported herewith it is probable that two hours of such heating would not prove detrimental.

Further investigation is needed before one can safely conclude that gathering the egs more than once each day during moderate or warm weather is beneficial from the standpoint of their hatching quality.

Influences of Attractive Nests

Little is known as to what extent the nature and location of the nest and the use of nest eggs influence egg production. Brown, an English poultry authority, says that the removal of the eggs from the nest has been one of the important factors in bringing about increased egg porduction in the domestication of the fowl.

The regular removal of the eggs from the nests of certain wild birds results in a marked increase in the number of eggs produced in a clutch. The experience of poultrymen in the management of geese, particularly, has led them to believe that the regular removal of the eggs from the nest will postpone broodiness and result in the production of more eggs during a season.

Although we do not have sufficient evidence to warrant the conclusion that the use of secluded nests and nest eggs have such a marked influence upon egg production directly, it is not too much to assume that their use will indirectly increase production just as the use of any other

ACADIA UNIVERSITY
WOLFVILLE - - Nova Scotia.
Departments
Arts and Sciences. Applied Science. Theology.
Degrees
B.A., B.Sc., B.Th., M.A., and certificates admitting to the best technical schools. First two years in Agriculture given as electives in B.Sc. course. First year in Medicine, Law, and Theology given as electives in B.A. course.
Special Courses
Courses in Surveying, Draughting, Shopwork, Chemistry, Electricity, and Bacteriology, for returned soldiers.
Equipment
Largest undergraduate faculty in the Maritime Provinces. Three new and splendidly equipped Science Buildings.
Expenses
Expenses light, and over $1,000.00 given in prizes and scholarships yearly. Send for calendar to
Rev. GEORGE B. CUTTEN, Ph.D., D.D., LL.D., President.
Next term begins October, 1st, 1919.

ACADIA LADIES' SEMINARY
WOLFVILLE - - Nova Scotia.
The Aim.—To prepare Girls and Young Women for Complete Living.
The Courses.—Twelve; including College Matriculation, General, Music, Art, Expression, Household Science, Business.
The Faculty.—Twenty-four Teachers of fine personality and Special Training.
The Equipment.—Modern and First Class in every respect.
A Junior School.—For Younger Pupils.
Information.—Write for illustrated book to
Rev. H. T. DeWOLFE, D.D., Principal.
Next term begins September 3rd, 1919.

Acadia Collegiate and Business Academy
A Residential School for Boys and Young Men
Ninety-first Year
Courses. — Collegiate, Manual Training, Business, Special Courses.
Features.—Modern Residence, Good Equipment, Ideal Location, Splendid Environment. Experienced Teaching Staff, Moderate Cost.
For illustrated Catalogue of Information apply to
Principal W. L. ARCHIBALD, Ph.D.,
WOLFVILLE - - Nova Scotia.
Next term opens September 3rd, 1919.

Dalhousie University
Halifax, N. S
Arts, Science, Engineering, Music, Law, Pharmacy, Medicine, Dentistry
ENTRANCE SCHOLARSHIPS:
Three of $200, five of $100, each.
Awarded on results of matriculation examinations, September 24-27, 1919.
One reserved for Halifax County, one for Cape Breton, one for New Brunswick, and one for Prince Edward Island.
FIRST YEAR SCHOLARSHIPS:
Three of $200, three of $100, each.
Awarded on results of first year, and tenable during second year.
DORMITORY ACCOMMODATION
is being provided for men students. Work on Women's Residence has begun. Provision will be made for women students until new building is ready.
REGISTRATION DAYS
in all Faculties September 29th and 30th. Halifax students must register on the 29th
LECTURES BEGIN
October 1st, 1919.

measure which adds to the general contentment and comfort of the stock may be expected to do so.

The Influence of Seclusion

Although secluded nests are commonly recommended to poultry keepers as preferable to others, no actual experiments or observations have beeen reported to substantiate the claim that they are more attractive or more satisfactory to the laying hen. In order to secure definite data on this point a flock of Rhode Island Red pullets housed in the new tile poultry house previously mentioned was placed in an experiment for a period of one month commencing the middle of February. They were housed in two pens but with the door between them kept open so that the hens could move freely from one pen to the other. Each pen was provided with two sections of nests, each section consisting of eight nests. During this experiment one section of nests in each pen was kept closed and the other one open.

Each day when the eggs were gathered the section of nests that had been open in each pen during the day was closed and the other one was opened to be kept thus for the next day. This eliminated the effect of any expected.

A total of 535 eggs was laid in the 32 nests during the experiment. Of these 251 eggs, or about 47 per cent. of the total, were gathered from the exposed or open nests and 284 eggs, or about 53 per cent, from the closed or more concealed nests. Expressed on the same basis as the results of the nest experiments, for each 100 eggs laid in the exposed nests, 113 eggs were laid in the concealed ones. Although the result shows a positive advantage efor the concealed nest, it is not so great as for the use of nest eggs.—By Geo. M. Turpin, of the Iowa Experimental Station.

EARLY PULLETS VS. OLD HENS FOR EGGS

For profitable early winter egg production the early hatched pullet is three times better than the late pullet, four times better than the yearling hen and thirty times better than the "aged" hen.

Early pullets are best for winter eggs. This has been demonstrated many times. The Poultry Division, Experimental Farm, has collected figures for several years and when the three months (November, December and January) only are taken into consideration the relative profitableness of the four ages is as noted above. If the six winter months were considered the contrast would not be so striking for the hens and the late pullets were just beginning to lay when the experiment closed. However, if eggs alone are to be considered we cannot afford to feed birds until towards spring before they produce. Even if desired for breeding it is a question if, with the high price of feed, we had not better rely upon the well matured pullet for hatching eggs next spring rather than feed hens that will not produce or only at a loss. Certainly there is no excuse whatever for keeping in our poultry houses late pullets whose eggs cost more than they are eworth and birds that are absolutely useless as breeders.

This summary is of results that extend over four years and are taken rfom several of the farms of the system so that the figures will indicate fairly well what may be expected for these three months.

These figures show that early pullets (hatched before May 1st) produced eggs at a cost of feed of 18.3 cents. The late pullets (hatched after May 15th) at a cost of 56 cents. The year old hens at a cost of78.2 cents, and for every dozen eggs laid by the hens in the aged class the cost of feed was $5.73.

Again these facts should be emphasized (1) that for profitable egg production birds should lay before February. (2) Early well-matured pullets are the only birds that may be expected to do this. (3) Late pullets as a rule will not pay to keep. (4) For eggs, hens are not profitable. (5) If we have a good flock of early pullets for the time being depend upon them for breeeding. (6) It is a national loss to keep birds that eat a dollar's worth of feed to proudce fifty cents' worth of eggs.

The frequent use of some good disinfectant in and around the poultry house will often prevent the accumulation of disease germs and help to keep the fowls in condition to be profitable

A SATISFACTORY DROPPINGS BOARD

Could you describe a good droppings board for a hen house? I want to get one that can be taken out easily and cleaned every day.—A. B.

Ans.—The most satisfactory droppings board that I have ever used is the concrete floor beneath the perches with a wide board set on edge in front of them to keep the litter from being scratched into the droppings. This "board" harbors no mites in its cracks, and is readily cleaned at convenient intervals with a shovel. If one desires a real droppings platform, however, it should be made from smooth lumber and preferably in sections so that it can readily be removed for cleaning. The cracks in and about droppings boards are breeding places for mites and necessitate frequent attention on the part of the caretaker; consequently it is well to dispense with them unless limited floor space requires their use.

Know your weeds while they are young in order that you may dispose of them before they pollute your grain fields.

MOUNT ALLISON LADIES' COLLEGE

Founded 1854. Session 1919-20

OPENS SEPTEMBER 8

¶This is the largest Residential Ladies' College in Canada.

¶WE STAND FOR—High Ideals, Soul Culture, Intellectual Equipment.

¶WE GIVE COURSES in—Music, Oratory, Household Science, Literature, Fine Arts and University Matriculation. Business Courses are provided by the Academy Affiliated with us.

¶WE POSSESS—An enviable reputation of almost continental scope.

¶Our Art Museum is a feature where we consider we stand without a peer. Free Calendar on application to

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N B. solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

There's joy in the smile of a comrade,
and joy in the blue of the sky
Who lives in the sunshine of friendship, has joy that no money can buy.
There is peace to be found in the valleys and calm in the shelter of trees,
And millions of people are happy in claiming such pleasures as these.
—Edgar A. Guest

MIRANDY ON SPOILING YOUR HELPMATE

By Dorothy Dix in the Good Housekeeping Magazine

Honey chile, is you ever done took notice dat hits seems lak all de lady angels is married to rapscallions, and vicey versey, as Brer Jinkins says, an' dat all dem men what is sheriffs from de skies is done tied up wid wives dat is she-devils?

Yassum, you sees dat kind of mixtry in so many homes dat when you runs acrost a grand, noble woman wid a halo shinin' aroun' her, you spects to find her fishin' a husband, what is a human shrimp, out of de gutter, and wearin' a black eye dat he give her as his thanks for takin' keer of him.

Lakwise, when you set yo' eyeballs on a man what leads de temperance movement and sticks by de hearthstone as close as a sick cat, and what gits hump-shouldered wukking for his fambly, an what gits up in de night an walks de baby wid de colic, mo' dan lakly you will find out dat he is united in de holy bonds to a wife what is a hussy dat's castin' sheep's-eyes at odder men, an' blowin' in his pay-envelop on britches-leg skirts an sech vanities.

Somehow hit don't look lak dere's no mutualness in matermony. You don't sca'cely ever see a husband and wife dat's patient an kind wid each odder an' sacerficin' demselves to each odder. Dat you don't! One or de odder of dem is done shouldered de whole job, an' is doin' all of de sacerficin', an' showin' all de patience and de kindness, whilst de odded one is a-tearin' hit out widout thinkin' of nobody but demselves.

Hit used to look mighty funny to me dat de good folks always had sech bad luck in marryin'. An' I prognosticated dat de reason of hit was dat they didn't tote no rabbit's foot, or else dat they sho' was mighty po' pickers, when it come to selectin' deir life pardners. But dat was befo' I done mix up in dis here marryin' business myself.

Now I knows dat dere ain't no conjer laid on de good dat makes dem tie up wid de bad, an dat turns matermony from a gran', sweet song to a cat fight in de back yard. Hit's de goodness of de good dat's at de bottom of all de trouble, and dat makes de badness of de bad.

Hit's de good women dat spiles de men dey marry and turns dem into bad husbands, and hit's de good men dat spiles de nice little gals dey leads to de altar, and turns dem into vixens.

Yassum, when we gits married, we's jest lak babies dat is born into a new worl', an' we kin be spiled jest as easy aas a baby kin. Or we kin be trained to behave ourselves an' be good jest lak a baby kin. How a husband or wife turns out depends on whedder de one had sense enough, or grit enough in deir craw, to let de odder one howl and shriek for what they wanted widout gittin' hit, or whedder he or she give in to save de fuss an' let de husband or de wife find out dat dey could always git deir way by makin' a row.

Now me, when I was fust married to Ike, co'se I wanted him to think dat I was dat meek and mild dat butter wouldn't melt in my mouf. So when he got to segasuatin' around wid dat fliberty-jiberty May Sue Jones, what I has always had my spicions dat she ain't no better dan she oughter be, an' he took to stayin' out of nights at de crap game, whilst I passed a excitin' evenin' at home watch' de baby sleep and patchin' his britches, I didn't say nothin' to him, dough I mos' chewed my tongue off to keep from doin' hit.

I was tryin' to live up to what I thought a noble, forbearin' wife had oughter be, so I'd welcome him home wid a glad, sweet smile, and de mo' I kep silent, and de mo' glad, sweet smiles I give him, de mo' he gallivanted around wid May Sue Jones, an' de later he stayed at de crap game, because I was spilin' him into thinkin' dat a man can tread de path of matermony wid one foot an' roam along de free road of de bachelor wid de odder foot.

Wellum, as soon as I seen de light, I went to hit, lak de Scripcher says to do. I begun to unspile dat man I had started out to spile. De nex' night, when Ike come home from de crap game, I wan't waitin' up for him wid no glad, sweet smile. I was waitin' up for him wid de rollin'-pin in one hand an' de stove-lifter in de odder, an' by de time he done got out of de horspital, hit seemed he had sorter los' his interest in games of chance. Leastways, he don't go to dem no mo'. An' de way I spressified myself 'bout what I was liable to do if I ever cotched him pergrinatin' roun' after any odder woman, makes him afraid to look at a skirt hangin' on a clothesline to dis very day.

Yassum, Ike suttinly has gone de name of bein' de most domestic man in Little Zion Church, an' he sho' has been a model husband, but de reason he'd good is becase I brought him up bp hand to walk in de way he should go.

Now Sis Hannah Jane, she ain't a probus woman like I is, dat's got a backbone lak a telefoam post. Sis Hannah Jane, se is jest lak a bowl full of jelly, an' de only reason dat anybody don't walk over her is becase dey is too kind to do hit.

Now Sis Hannah Jane is married to Brer Si, what's a rich man wid money in de bank, but Sis Hannah Jane looks lak somebody done took her out of de ragbag, dough she hones an' pines for good clothes an' flower bonnets lak ev'ry woman does. But she don't git 'em becase Brer Si is done got de notion dat shut-waists grows on a woman lak feathers does on a hen, an' dat she can run a house on air, an' dat a man can't waste money in no foolisher wap dan spendin' hit on his wife.

Now all of dat is mos'ly Sis Hannah Jane's fault. When dey was fust married, she was so anxious to please Brer Si dat she made over her weddin' frocks until dere warn't a scrap of 'em left, an' she wore her last year's birdnest on her haid for a hat, an' inched an' pinched an' suiqnched to save every penny, ontil she got Brer Si to think dat she was a miracle worker dat could git along widout money.

She done spiled him becase she didn't ax for anything for herself, an' what a woman don't ax for, she don't git. Yassum, you take hit from me, dat if a wife eats de back of de chicken an' gives her husband de white meat, an' if she wears de ole clothes an' lets him have de new suit one time, she has got to eat de back of de chicken an' wear de ole clothes as long as she lives. An' her husband won't thank her for hit, nuther. He'll jest think she is a plum idjut to let him have de best of hit. I ain't got no pity for dese here self-sacerficin' wives. Dey could have trained deir husbands to divide wid 'em if dey had had any spunk in 'em.

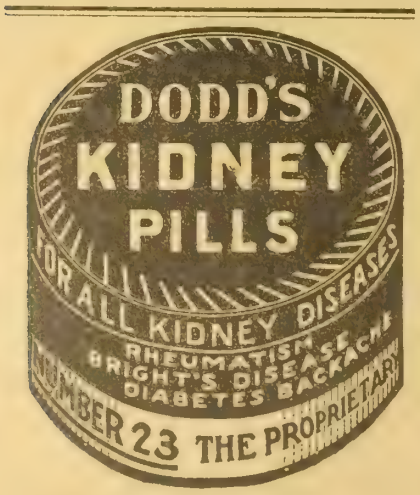
And men spile deir wives jes de same as womn do deir husbands, an' turn women who would 'a made puffectly good helpmates into millstones around deir necks.

Dere's Brer Hiram what is let Sis Ailsie keep his nose to de grindstone all of his life by her extravagance an' what throws mo' out of de back do' wid a spoon dan he can put in at de front do' wid a shovel. An' dere's Brer Thomas what has to git up an' cook his own breakfast an' live in a house lak a pigsty becase Sis Phrony is lazy an' shiftless an' was born too tired to wuk, an' dere's a million odder men dat I know dat walks in fear an' tremblin' of wives dat has de high strikes ev'y time dey's crossed.

All of dem women is des been spiled rotten by deir husbands. Dey's jest bad chillen an' hit's Gawd's pity dat when a woman acts lak a chile she can't be treated lak a chile, an' spanked until she's good. But dey can't, for a man dassent strike a woman no matter how much she needs hit an' what good hit would do her.

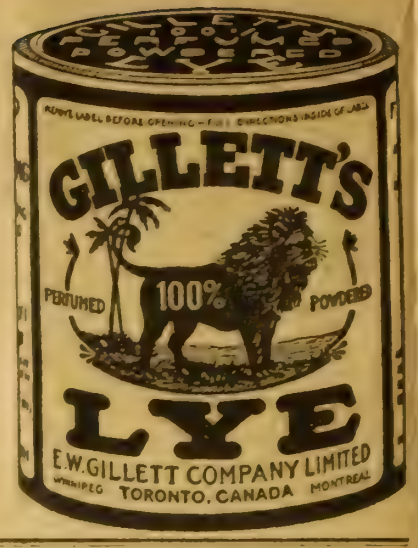
An' wome nknow dis, an' dat's why dey cry an' howl for what dey want jest lak a baby does. My advice to any young man dat is gettin' married is to pervide hisself wid a waterproof shut, at wll shed his bride's tears lak a duck des water, an' dat will keep his backbone dry so hit won't wilt down an' keep him from doing his duty by her an' makin' her behave herself.

Yassum, we mos'ly make our bad husbands an' wives for ourselves by spiling good material wid our bunglin'. But hit's kinder sorrerful dat we can't treat our husbands an' wives lak we would lak to widout ruining 'em, ain't hit?



LABOR DAY

Labor may be defined as an effort for the satisfying of human need. We are prone to think of the laboring class as those who work with their hands and win their bread by the sweat of their brow, but since all mankind has various needs, labor becomes the blessing and requisite of all. The capitalist and his money, alone, are quite useless, and only when his labor of mind ha decided on its investment does it begin as a factor in this work of supplying human need; and ere it ends, trust companies, banks, bankers, and manufacturers are all employed in labor. These in turn require the labor of man yin order to operate their plans and make practical their executive ability. Labor, then, marks the beginning and the end of all accomplishments, all progress and all civilization, as all laborers, both mental and



physical, require sustenance in order that they may work, the labor of the farmer must be employed. To assist him, he must turn to manufacturers and so we see that each class of labor depends upon another and no one individual or class is independent of another.

It was the recogniition of this fact that caused labor day to be set apart as a holiday. It was first observed in the United States and there, as in Canada, the holiday falls on the first Monday of September. Due to a Labor Conference in Berlin in 1890, May 1st is to some extent observed in Europe.

The progress that labor has made and the power it holds, is often demonstrated in the labor strikes which occur in cities. These strikes are the result of labor unions, which set a scale or standard of wages, length of woring day, etc., to which regulations employers must concede or the men, as one man, refuse to work, and the operations of the company are at a stand still. Even if they continue to refuse to meet the demands of union men, and secure non-union men at other terms, the shock to their business is so great, both from loss of time and less competent labor, that usually some concessions are made and the union triumphs. These strikes result from the knowledge that labor is more essential than capital and are right or wrong according to one's viewpoint. Sometimes they mean great loss to the striker, and his family is oftentimes reduced from comfortable living to dire poverty. Homes are often lost waiting for a turn in the tide of affairs and the discouraged striker often finds the saloon his final

SUFFERED 5 YEARS WITH HEART TROUBLE.

Through one cause or other a large majority of people are troubled with some form of heart trouble but do not know it.

When the heart becomes affected there ensues a feeling of a choking sensation, the breath becomes so short it is hard to breathe and you feel as if you were smothering, you become weak and dizzy, the heart palpitates, throbs and beats irregularly.

On the first sign of the heart becoming weakened you will find that a few boxes of Milburn's Heart and Nerve Pills will strengthen and invigorate it so that it beats strong and regular, and the lost vitality is replaced by vigor and energy.

Mr. Stephen Crouse, East Clifford, N.S., writes:—"I suffered for five years with heart trouble. I could hardly walk to the barn without resting I used to get so short of breath. The doctors could not help me. My wife told me about Milburn's Heart and Nerve Pills. I got a box and felt better; three boxes made me quite well. I am now helping my son work the farm; and can truthfully say I feel like a different man. I can highly recommend your pills to any one who has a weak heart."

Price 50c. a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

Every 10c Packet of
WILSON'S
FLY PADS
WILL KILL MORE FLIES THAN $8.00 WORTH OF ANY STICKY FLY CATCHER

Clean to handle. Sold by all Druggists, Grocers and General Stores.

comfort However, labor unions, under wise management and fair-minded thinking men, have strengthened certain labor classes, have done much good to the individual, and the general public has profited in the benefit derived from skillfully accomplished work.—Written by Miss Elizabeth M. Galloway, of the Centre Napan Women's Institute.

HOT-WEATHER RULES

1. Load lightly, and drive slowly.
2. Stop in the shade, if possible.
3. Water your horse as often as possible. So long as a horse is working, water in small quantities will not hurt him. But let him drink only a few swallows if he is going to stand still. Do not fail to water him at night after he has eaten his hay.
4. When he comes in after work, sponge off the harness marks and sweat, his eyes, his nose and mouth, and the dock. Wash his feet but not his legs.
5. If the thermometer is 75 degrees or higher, wipe him all over with a damp sponge, using vinegar water if possible. Do not wash the horse at night.
6. Saturday night, give a bran mash, lukewarm; and add a tablespoonful of saltpetre.
7. Do not use a horse hat, unless it is a canopy-top hat. The ordinary bell-shaped hat does more harm than good.
8. A sponge on top of the head, or even a cloth, is good if kept wet. If dry it is worse than nothing.
9. If the horse is overcome by heat, get him into the shade, remove harness and bridle, wash out his mouth, sponge him all over, shower his legs, and give him two ounces of aromatic spirits of ammoniaa, or two ounces of sweet spirits of nitre, in a pint of water; or give him a pint of coffee warm. Cool his head at once, using cold water, or, if necessary, chopped ice, wrapped in a cloth.
10. If the horse is off his feed, try him with two quarts of oats mixed with bran and a little water, and add a little salt or sugar. Or give him oatmeal gruel or barley water to drink.
11. Watch your horse. If he stops sweating suddenly, or if he breathes short and quick, or if his ears droop, or if he stands with his legs braced sideways, he is in danger of a heat or sun stroke and needs attention at once.
12. If it is so hot that the horse sweats in the stable at night tie him outside, with bedding under him. Unless he cools off during the night he cannot well stand the next day's heat.

Spanking Doesn't Cure!

Don't think children can be cured of bed-wetting by spanking them. The trouble is constitutional, the child cannot help it. I will send **FREE** to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatment is highly recommended to adults troubled with urine difficulties by day or night. Write for free trial treatment.

WHAT CAN BE DONE WITH CRAB APPLES

Crab apple trees produce almost every year, and grow in any out-of-the-way corner with little attention. A few trees will supply fruit for jelly and preserves much more cheaply than the high-priced apples on the market. Moreover, the quality is just as good, if not better.

To make crab apple jelly, wash the crabs thoroughly, remove the leaves and blossom ends, cut out the decayed spots and place the apples in a preserving kettle. It is unnecessary to peel the fruit or to remove the cores and stems. Cover the apples well with cold water and cook them slowly until they become very much broken. The longer and more slowly they cook the better will be the flavor and color of the jelly. Pour the apples and juice into a jelly bag, and drain them overnight without pressure.

n tIhe morning measure the juice and add an equal amount of granulated cane sugar. Stir the juice until the sugar is thoroughly dissolved. Pour the sweetened juice into large-sized rather shallow granite kettles, with so little in each that iti will begin boiling very soon after it is placed over the refi. Crab apple jelly requires very little boiling. As soon as the juice becomes thick enough pour it into glasses.

A surprising amount of juice, of course contaaining some pulp, may be secured by pressing the apples left in the jelly bag. Jelly can be made from this juice also. If this second grade juice is pressed out the remaining pulp should be disposed of, as it is too dry to be palatable. On the other hand if the juice is not pressed out, the pulp may be made into fairly palatable crab apple butter. Some people consider the flavor of the jelly to be improved if a stick of cinnamon is added to the crabs before they are boiled.

Butter and Pickles

Crab apple butter is inferior to that made from other apples, but even at that it is very palatable indeed. Wash the crab apples thoroughly, remove the leaves and blossom ends, place the crabs in a large preserving kettle and cover them well with cold water. Allow them to cook slowly until they become thoroughly soft. Remove them from the fire and allow them to cool enough to handle. Empty both the apples and the juice into a granite colander and rub them through it. Place the pulp and juice together in a stone crock with enough sugar to lake the butter as sweet as desired; usually about a cupful of sugar to a quart of pulp and juice is satisfactory. Add also cloves and cinnamon to suit taste. Mix the sugar and seasoning with the pulp and juice and then place the crock in a moderately hot oven. Stir the butter once every ten or fifteen minutes. When it becomes thick like mush, seal it in jars.

Crab apple preserves are superior in flavor, shape and color to those made from other apples. Prepare a heavy sirup by boiling together for fifteen minutes sugar and water in the proportion of one quart of sugar to one quart of water. Select perfect, well colored crab apples, wash them thoroughly and remove the blossom ends; leave the stems and peelings. Place the crabs in the sirup and stew them gently until they are well done. Lift them out and put them into glass jars. Unless the sirup is very thick, boil it until it becomes like molasses; then fill the jars to overflowing and seal.

For pickled crab apples select only perfect ripe fruit. Wash the crabs thoroughly, remove the blossom ends, being careful not to break or remove the stems, and put the apples into a preserving kettle with enough vinegar to cover them. Boil them slowly until they become tender, but remove them before they fall to pieces and place them in the jars; measure out this amount, and an extra pint to allow for boiling away, from the liquid in which the crabs were cooked. Add one and half pints of brown sugar for each pint of vinegar, and also a bag containing two sticks of cinnamon and three tablespoonfuls of cloves; boil the mixture for thirty minutes. Then pour the boiling vinegar over the crab apples and seal the jars.

Limited
MONTREAL

HAD DYSENTERY

Was So Weak She Had To Go To Bed.

Mrs Charles Buchanan, West Monkton, Ont., writes:—"I took Dr Fowler's Extract of Wild Strawberry when I had dysentery so bad I passed nothing but blood and water. I got medicine from our doctor, but it failed to help me. A friend of mine dropped into see me one afternoon. I was so weak I was in bed. She told me what "Dr. Fowler's" had done for her little boy, and she went home and got the bottle she always kept in her medicine chest, and believe me four doses helped me so I could get up and do my work. I took two more doses and I was as normal as I should be. I would not be without it now if it were five dollars a bottle. My husband has used it since I did, for diarrhoea and he got splendid results. You may publish this if you wish, as it may lead some other sufferer to a cure."

Dr. Fowler's Extract of Wild Strawberry for the past 74 years has had phenomenal success in all cases of diarrhoea, dysentery, cramps, colic, cholera morbus, cholera infantum, summer complaint and bowel complaints of old and young.

If you want to be on the safe side, if you don't want to experiment or take chances as to results, refuse any and every bowel complaint compound that is offered you and insist on the old reliable "Dr. Fowler's."

Price 35c. a bottle at all dealers. Put up only by The T. Milburn Co., Limited, Toronto, Ont.

RAW FRUIT DESSERTS

Rhubarb possesses the faculty of harmonizing with other fruits in any combination. The acid juice congeals readily in making rhubarb jelly; and in combination with peach, orange, quince, strawberry, and current juices, it assists these latter to jelly without changing their flavors. The juice of the rhubarb can be brought to the boiling point, sealed and put away to use in combination with the later fruits.

Molded ice and Rhubarb

20 medium-sized stalks green rhubarb, 1 quart water, 1½ cupfuls light brown sugar, 1 cupful rice.

Cut rhubarb in small pieces and boil until soft. Remove from fire and drain as dry as possible; mash and add brown sugar. Boil rice until soft in water. Mix rhubarb and rice, beating thoroughly. Mold in slightly buttered cups and place on ice until cold. Take from molds just before serving and serve with hard sauce.

Rhubarb With Raisins

2 pints rhubarb cut in inch pieces, 1 cupful raisins, ¾ cupful sugar.

Put rhubarb in a saucepan over a very low fire until the juice runs freely. Do not let it at any time boil hard. Add the raisins and let this boil until the rhubarb is nearly reduced to a pulp; then add sugar. Boil up, remove from fire, and put aside to cool. Serve cold with cream.

Rhubarb and Banana Dessert.

1 pound rhubarb, 1 cupful sugar, 1¼ tablespoonfuls gelatin.

Steam the rhubarb, which has been cut in pieces, with the sugar and one-half cupful water; when thoroughly cooked add gelatin which has been soaked in one-fourth cupful cold water for half an hour.

1 cupful banana pulp, Juice of half a lemon; ½ cupful orange juice; ½ cupful sugar; 1½ tablespoonfuls gelatin; 1 cupful whipped cream.

To the banana pulp add lemon and orange juice, sugar, and gelatin soaked in cold water, as above directed. When beginning to set, fold in the whipped cream. Put a layer of the rhubarb jelly in a mold, then a layer of the banana cream, alternating until the mold is filled. Place in the ice box to harden. When ready to serve, unmold and garnish with whipped cream flavored with banana.

Cherry Cup

Seed one quart of sweet cherries. Put one pineapple through the food chopper. Combine the fruits with one-half cupful sugar, and chill. When ready to serve, pour over the fruit one-fourth cupful lemon juice and one-half cupful orange juice mixed with one-half cupful sugar. Serve in small glasses. Walnut meats and marshmallows may be added; or cream, sweetened and whipped until stiff, may be heaped on top.

A Dainty Strawberry Dessert

1 cupful ripe strawberries, 1 cupful sugar, 2 egg whites, stale cake.

Mash the berries and stir in the sugar. Beat the whites of the eggs stiff; then put in the berries and sugar and whip stiff. Put a layer of stale cake in the bottom of a dish and pour the strawberry fluff over it. In about an hour the cake will be permeated and softened with the juices while the fluff on top is firmer than before. If you desire to make the dish more ornamental, drop spoonfuls of whipped cream on the meringue, putting a strawberry and a bit of green angelica or real strawberry leaves on each.

Strawberry Blanc Mange

1 quart milk, ¼ cupful sugar, 1 cupful strawberry juice, 4 tablespoonfuls cornstarch.

Heat milk to boiling point; add sugar, strawberry juice, and cornstarch which has been rubber smooth in a little cold milk. Cook until thick, and pour into wet molds. When firm turn out and garnish with whole strawberries and serve with sweetened whipped cream.

A MESSAGE TO WOMEN!!

Mrs. M. Summers, Box 309 Windsor, Ont.

THE VALUE OF FRUIT AS A FOOD

All our cultivated fruits have a history behind them, running back to the tiime when the earliest gardeners picked out the best species from the wild and transplanted the tree or bush to a plot in the home grounds.

Delicately flavoured apples or juicy seedless oranges are the result of hundreds of years of painstaking effort. Improvements in size and quality have come through careful selection, aided by chance cross fertilization, which gave rise to new types. Each advance made, gave encouragement to further effort and so great have been the transformations that it is difficult to trace most of the modern forms back to the original species.

Fruits are divided into two classes —flavored and food fruits. Food fruits contain more than 20% solids; flavored fruits are apples, pears, quinces, oranges, lemons, lime, etc. Food fruits are prune, date, raisins, banana, fig, etc.

The fig is highly nutritious owing to the large amount of sugar in its composition. It is a laxative food. Banana is also highly nutritious. It is reported to yield more fruit to the acre than almost any other plant; one cluster may have from 160 to 180 bananas. There is a banana meal which is made from the unripe banana. It is dried, ground and used in making bread.

Peaches are not nutritious, but are valued for their delicate flavor. Since they contain little sugar they are valuable to a diabetic patient. Olives are used as appetizers. They are gathered before they are quite ripe, steeped in lime water and pickled in brine to remove disagreeable taste. We obtain olive oil from the olive.

The apple, the king of fruits, was in its original wild form, small in size, often very acid or bitter and indigestible, and not much like the splendid apple that we have with us nearly all the year round which is so agreeable to the palate. How ever strawberries happened to be named, whether they were strung on straw and sold originally thus in lands across the sea, or whether they are so called because they need a heavy mulch of straw to bring them to perfection, matters not. They are considered universally "The Queen of Berries", and have a most important place in the early summer diet. The chief quality of strawberries is the acid; they contain one of the strongest fruit acids found in nature. This national tonic is most beneficial to the still sluggish blood left by winter's temperature, and is appreciated and enjoyed by most people. One of the benefits of this natural acid is lost if the fruit is cooked. It is unquestionably a fruit to be eaten raw.

If cooked, however, it is best to make a syrup first, dropping the ber-

ries in only at the last moment. This will preserve their shape, but most important, their flavor.

The cranberry, most persons regard as an adjunct to their Thanksgiving or Christmas dinner. Few think of it as a tonic provideed by Mother Nature to cleanse and purify the system during the long winter months, when few fresh fruits are available. From the Arctic regions, southward, this fruit is greatly valued and appreciated. During the nightless summer days the Scandanavian peasants make it their business to gather the red berries and string them in long chains for drying for the winter season.

In Russia the berry is used in wine making, while in many foreign countries it serves for making poultices which are applied externally for the purpose of removing inflammation. Few ships leave winter ports during the winter months that are not supplied with a goodly stock of these berries.

The cranberry should indeed be more widely used, not alone on account of its medicinal properties, but because of its culinary possibilities, which are more numerous than is generally supposed. Not only does it make exbellent sauces, puddings, pies, etc., but it may be used for jams, syrups and vinegar.

Fresh and cooked fruits hold an unique place in the dietary. Too often fruit is considered as simply a luxury for occasional rather than daily use, but the judicious use of both fresh and preserved fruits means better health and satisfaction for each member of the family. If possible, fruit should be served for breakfast. Each fruit has a season at which it is at its best and cheapest, then it is that the housewife, with an eye to future needs, is desirous of storing up a supply against a day of scarcity.

Two Years of Pain Then Quick Relief

John Weidman Used Dodd's Kidney Pills

And His Backache From Which he Had Long Suffered Was Cured Completely.

Springside, Sask., Aug. 24th (Special) "Dodd's Kidney Pills are worth their weight in gold." This glowing tribute to the good old Canadian kidney remedy comes from the lips of Mr. John Weidman, a well-known and highly-respected resident here. And Mr. Weidman justifies the tribute out of his own experience.

"I was suffering from backache for two years," he says. "I could hardly stand up straight. I tried all kinds of medicines but none of them seemed to ge me relief. My back seemed to get worse all th time.

"Then I decided to try Dodd's Kidney Pills and sent for two boxes. I used one up and my back improved. I used four boxes in all. They cured me completely."

Mr. Weidman's lame back was caused by sick kidneys. That's why he got such prompt and permanent relief from Dodd's Kidney Pills. They act directly on the kidneys strengthening them and enabling them to do their full work of straining all the impurities out of the blood. Impurities in the blood are the seeds of disease. Dodd's Kidney Pills make good health by removing the seeds of disease.

FRUIT DESSERTS

(Janet McKenzie Hill)

Punch

The foundation of these ices is a fruit sherbet. To this is added a meringue and then frozen. This variety of ice is soft and eaten with a spoon from the glass in which it is served. A quart of punch is the quantity called for at a dinner of twelve covers.

Peach Sherbet from Fresh Fruit

(Italian Method)

1 quart peach pulp, 1 cup orange juice, juice 1 lemon, 1½ cups sugar.

Orange Sherbet with Syrup

Boil 1 pint (one pound) of sugar and one quart (one pound) of water twenty minutes. This should make about 2½ cups of syrup. To this syrup add one cup lemon juice or two cups orange, strawberry or peach pulp and juice. (If the orange, strawberry or peach pulp and juice are used to make the sherbet, add the juice of a lemon to each quart of the mixture to bring out the flavor.) Before freezing, add one teaspoonful of gelatine, softened in cold water and dissolved over hot water, or, after freezing fruit mixture sufficiently, beat into it a meringue made by beating one quarter cup of syrup (at the threaad degree) into the white of an egg beaten until foamy.

Coffee Sherbet

¾ cup fresh ground coffee, ½ cup cold water, white and crushed shell of 1 egg, 6 cups boiling water, 1½ cups suggar or 2¼ cups medium thin syrup, 2 teaspoonfuls granulated gelatine, (softened in cold water).

Mix ground coffee with egg and cold water, add boiling water and boil 3 minutes. Strain, add dissolved gelatine and strain again over the sugar or syrup. Cool and freeze. Serve with whipped cream sweetened and flavored.

Grape Sherbet

1 quart water, 1 pint sugar, 1 pint grape juice, juice of 2 lemons, 1 teaspoonful gelatine (softened in cold water).

Make syrup of sugar and water (similar to Orange Sherbet) add fruit juice. Before freezing add dissolved gelatine.

Fruit Cup

Let slices of peeled peaches, bits of prepared pineapple, stoned cherries, peeled plums, white grapes (seeded and skinned) and orange sections stand in their own juice and a medium thin syrup, surrounded by ice until thoroughly chilled. To serve, place in tall wine glasses and cover with a few spoonfuls of fruit sherbet flavored to taste.

EASY JELLY MAKING

It is as easy to make good jelly as it is to make good apple sauce, only that it takes a few moments longer. If you follow exactly the following rule, you can make jelly of a delicious fineness and color and taste. When you cook the fruit use just a little water because the water has to be cooked out; the more you put in the more pou will have to cook out. Use your over-ripe mussy fruit for jam, but use only the best for jelly.

Thirty-five Minute Jelly

With many fruits you can make jelly in 35 minutes from the time you put the fruit on the stove until you have the liquid in the glasses. It is easier to do it slower; let the fruit heat slowly then boil briskly until very soft. Hard boiling makes fruit go to pieces and that is what you want. The less time spent in cooking the fruit the better the flavor of the jelly. Now for the rule.

Grapes, Apples, Currants, Green Grapes, Greenish Plums, etc.

Fix for the jelly by having them clean. You need never peel anything for jelly as the peel will make the liquid "jell" better and it gives the jelly a better color and flavor. Stem grapes and currants. Bring to a boil and then boil very rapidly until soft; mash them if necessary to make the juice come out. Put the fruit in a bag made from a piece of cheese cloth, cut square and sewed up diagonally so as to form a cornucopia. Fasten the bag to some convenient place to drain, or if in a hurry squeeze the juice out. This gives you a good deal more jelly if quantity is what you are after, and it jellies quicker if it is pressed some, but the jelly will not be so clear, although it is extremely nice. When the juice has been pressed out or has been dripped out, measure it and put it over the fire. Measure as much sugar as you have juice and put this in the oven to heat. Let the juice come to a quick boil uncovered. Let it boil exactly 20 minutes then add the sugar and let it boil up. Do not cook it two minutes after it boils up again if the sugar is all melted by this time. Skim off any skum and pour into glasses and you are done. Manp times the jelly will get hard almost at once but in some cases it will not be real hard for some days after it has been made, and it is better so, for jelly that hardens at once is apt to get too solid when it is kept any length of time. Do not cover soft jelly with paraffin until it hardens; when it does pour melted paraffin over the top to prevent it getting any harder, and to prevent moulding. It can be lifted off when the jelly is wanted for use.

Many fruits will not jelly alone. With these a mild-flavored but sour apple should be used, half and half, as apples have as much jelly making properties as any known fruit.

You can use apples whole for jelly, simply washing them clean, but quinces should always have the stones removed for these possess a certain property that prevents anything from jellying. Without the stones this fruit jellies easily and makes one of the most delicious jelly known. The juice from cooked quince parings when added to apple juice will flavor the apple jelly richly. Peach juice and apple juice is a combination that makes delicious jelly. Also combinations of pineapple and apple, raspberry and currant and so on.

HARVESTING RED CLOVER SEED

During a number of years the Dominion Experimental Farms have advocated the use of Canadian-grown red clover seed in preference to imported chiefly on the ground that the home-grown seed produces crops which are likely to be heavier than the crops grown from imported seed. As a result of this propaganda, and also because clover seed raising has been found to be a profitable business, the growing of red clover for seed is gaining in popularity although, as yet, it has not developed into the prominent business which it is bound to become if pursued rationally.

As is well known, the seed crop is practically always taken from the second crop of the season. Assuming that the second crop has been set aside for seed production, it should be harvested when most of the heads have turned brown and the stems of the plants begin to dry up. If the crop is cut before it has reached the said stage of development, the quality of the seed is apt to be inferior because a too large percentage of the seed will be immature and shrunken. As a consequence, the vitality will be low and the general appearance of the seed inferior. If, on the other hand, the crop is left standing too long, considerable losses may be suffered for the reason that, when the crop is overripe, the heads easily break off and shatter, especially if the harvesting is done in warm and dry weather. It is therefore important that the seed crop be harvested at the right time.

If you are not sure about when to cut your clover seed crop, pick out some average heads and rub them in the palm of your hand. If you are rubbing out firm and well-developed seed of a pronounced colour, then it is time to cut.

The seed crop may be cut either with a mower or with a binder, depending on circumstances. If the clover is only a foot high or less, the mower may be used; if it is more than a foot high, the binder may prove more satisfactory.

If the seed crop is being cut with a mower, it is most desirable to arrange to have the swath moved out from the uncut crop before a round is completed, because otherwise the horses will have to walk on the swath and, in doing so, will thresh out quantities of seed which of course will be lost. The moving out of the swath from the standing crop may be done by a clover buncher attachment or by two men with hand rakes following the mower.

If the seed crop is to be cut with a binder, the latter should be adjusted so that it will trip continuously. Furthermore, the side boards should be removed so that the clover is given a free course to the ground.

The crop should be left in loose windrows and may, when properly dried out, be gathered with the barley fork. It may be left in the stack or in the barn, as preferred, until it is convenient to thresh. The threshing should, if possible, take place in cold and dry weather.

AFTER HARVEST CULTIVATION

The effects of cultivation in general are threefold—the aeration of the soil, the conservation of moisture and the destruction of weeds.

The cycle of cultivation during the crop year consists of after harvest cultivation, fall ploughing and spring seed-bed preparation. Each of these three distinct phases must be practised systematically if the most suitable seed-bed condition are to be consistently maintained.

After harvest cultivation is the most economical of the means employed in the control of weeds.

Maximum horse eand engine power and improved labor-saving implements with a minimum of manual labor can be used to advantage. Efficient time-saving methods are factors in lowering the cost of production charges and in showing a profit.

After harvest cultivation should begin promptly on sod, stubble land and on pasture areas to be broken for grain; hoed crops such as potatoes and roots; all weed-infested land to be cropped and clay soils for all crops including corn for ensilage or seed purposes.

The cropping plan that cannot be arranged so that each grain crop is seeded down to grasses and clovers, and where two grain crops follow in succession, should provide for the after cultivation of stubble land.

Where this factor in weed control, soil improvement and moisture conservation is overlooked the result is low yields, impoverished and weed infested fields.

The methods employed in after harvest cultiviation are several. Pasture and sod land should be shallow ploughed, rolled or packed and disced as soon as possible after the crop of hay has been removed or the field has been pastured off. Discing should be continued until it is possible to operate a stiff-tooth cultivator without tearing up sods. The latter implement is very valuable used in the eradication of such weeds as "Quack grass" (agropyrum repens L.) where it is advisable to draw the root stalks to the surface.

Stubble land may be shallow ploughed, disced or cultivated, depending upon nature and condition of soil. Usually it is most economical and satisfactory to shallow plough and disc or cultivate, depending on conditions as outlined for sod land.

Successful after-harvest cultivation demands thoroughness and perserverance. These conditions must be fulfilled for encouraging results. Haphazard attempts are useless.

Before the freeze-up, all after-harvest cultivated land should be ridged or ploughed as deeply as the surface soil will allow.

W. L. GRAHAM,
Assistant Dom. Field Husbandman.

RIPENING TOMATOES IN A SHORT SEASON

(Experimental Farms Note)

In a comparativey short growing season, the tomato usually produces a large crop of green fruit but only in favorable summers is there much ripe fruit produced unless special measures are taken to hasten ripening. At Brandon Experimental Farm considerable success has been attained in forcing early maturing of tomatoes and the methods which have proven most successful may be of general interest.

Choice of variety.—Only the very earliest varieties should be used. The Earliana variety and strains developed from it, such as Alacrity and Sunnybrook, are the best to use. Earliness must be the one chief consideration and other points must be made secondary to it.

Location.—Tomatoes should be grown in a well sheltered garden where the wind is prevented from beating them about. They should be in the open sunlight; shade is fatal to success. If it is possible to make any choice in regard to soil, a sharp loam with considerabe proportion of sand is preferable to heavier soils.

Starting.—At Brandon the tomato seed is planted in seed boxes in a hot bed the first week of April. An earlier start can be made when seed is started in the house but more satisfactory results are attained in a hotbed. By starting at that time, it is possible to have planats in blossom by trans-

SEPTEMBER 13, 15, 16, 17, 18, 19, 20

planting them. While in the hotbed the young plants are moved twice, first pricked out to single plants and then transplanted for more room as they grow larger.

Planting.—The timatoes are planted in the open about June 10th. Earlier than that it is too risky for frost in Manitboa, and while that date is not entirely free from frost risk, later planting would have too short a remaining season for the development required. The tomato plants should be given plenty of room. Putting rows four feet apart and plants two feet apart in the row is about the right spacing.

Staking.—The tomato plants should be staked upright and should be pruned to reduce the foilage. These operations probably have a greater effect in inducing early maturity than anything else, with the possible exception of variety.

The object is to allow the sun to shine more directly on the stems and fruit to check the production of excessive foilage and late blossoms. The plant should be trained to grow to one upright stem instead of numerous spreading branches. It should be fastened upright by driving a stake in beside it and tying to the stake. Or wires may be stretched along a row, though this method is not as satisfactory as staking. The growth should be prevented from becoming dense and bushy by pinching off the buds that appear in the axils of the branches. And in addition, part of the foilage may be pruned off. After a sufficient amount of fruit has been formed, later blossoms should be picked off so as to force the growth and maturity of the earlier fruit.—W. C. McKillican, Experimental Farm, Brandon, Man.

SUMMER FEEDING OF BREEDING SWINE

"Economical Production" should be the watchword of every producer whether it be of pork, beef, or mutton. With mill feeds at the prices prevailing today and the prospect of an increase in price of some of the more essential feeds it behooves the producer to study very carefully the feeding problem and adopt any method that will tend to give him the cheapest production.

Now all too often has the breeding herd on the average farm cost from one-third to one-half more than it should have to summer them, which of course, lessens the profit to be realized from such a herd. At the Experimental Farm it has ben shown that a herd of brood sows can be carried through the summer in a good, thriving condition and raise good litters on pasturage and not cost over half as much as though they had been housed all summer and fde on mill feeds. Moreover, the sows were more healthy and farrowed litters that were more erobust. Yes, and the mortality was much lower than among those sows kept inside all summer.

For "economical production" then, the brood sow should live out all summer in the open on uncontaminated soil, grazing on some succuent pasturage, thereby developing bone, muscle and constitution. The average grasses do not supply the most satisfactory pasture for swine, yet they are better than keeping them in the house. Among the most suitable are rape or a legume such as clover or alfafa if you can grow it successfully. Peas, oats and vetches also make excellent pasture for swine. Small fields of any of those named can be sown. Allow the swine to go in just for a short time at first until they become accustomed to it, leaving them a little longer each day until soon they may remain all the time and not eat any more than is sufficient for their needs. While a pig can barely subsist on grass alone, the legumes or rape will more than sustain life and so leave for produeing increase all the extra feed supplied. Therefore in addition to this succulent food there should be fed a small allowance of wheat middlings, bran, linseed oil meal or dairy product, thereby supplying the brood sow with the muscle and bone-forming mateerial that is essential. This should not constitute more than about one-third of the ration of concentrates. The remainder of the carbohydrates can be supplied with an addition of grain such as corn, oats or barley. The daily allowance of concentrates should be just sufficient to keep the sow in a good thriving condition, but not sufficient to make them satisfied. Otherwise they will not forage very much, but become lazy and the consequences are they will lie idle in a shady nook or under a tree.

No one can state definitely the amount to feed a pig. The feeder himself must be the judge. Study carefully the individual; regulate the extra feed given just to keep the animal thriving yet activiely forgaing to appease its hunger. In this way a herd of brood sows can be brought through the summer very cheaply and in a much healthier condition than in any other way.

Summer shelters for brood sows can be very cheaply made by building small cabins, say 10 x 12 on runners, so that the cabin can easily be moved from one field to another. For further information on this subject write to your nearest Experimental Farm and they will be only too pleased to give you what information they can that will be of assistance to you, and will also send you a sketch showing how these hog cabins may be constructed.

W. W. BAIRD,
Supt. Experimental Farm, Napan, N.S.

Were all the merits of red clover emblazoned in letters of gold on a arge canvas, it would fail to convey to the mind a full estimate of its true value.—Harlan.

Ford

Electric Starting and Lighting

NO car has a better starting and lighting system than that now available to purchasers of Ford Cars.

It is a Ford product, built into the motor—

—a positive starter as reliable as the motor itself:

—a powerful lighting system, uniform under all engine speeds.

On the open models—Touring Cars and Runabouts—it is OPTIONAL EQUIPMENT.

On closed cars—Sedans and Coupes—it is STANDARD EQUIPMENT.

On all models the Ford Standard Magneto also provides ignition independent of the batteries.

See the Ford car with this new equipment.

Ford Runabout $660; Touring $690
On open models the Electric Starting and Lighting Equipment is $100 extra.
Coupe $975; Sedan $1175 (closed model prices include Electric Starting and Lighting Equipment).
These prices are F. O. B. Ford, Ont. and do not include the War Tax. 111

Ford Motor Company of Canada, Limited, Ford, Ont.

Hints for Motorists

ALBERT L. CLOUGH
Editor Motor Service Bureau Review of Reviews

THE "DEEP BREATHING" ENGINE

Undoubtedly the most important respect in which the light weight, high speed, high duty vehicle engine of today excels the heavy, slow speed engine, of low weight efficiency, produced a half dozen or so years ago is that the former is a "deep breathing engine," and the latter is not. The ideal engine, in this respect, is the one that can take into each cylinder, during each cycle, the full weight of mixture which the cylinder will hold at atmospheric pressure and temperature and do this no matter how fast it runs. No engine ever built will actually accomplish this, but many recent engines go a long ways toward doing it and run to very high speeds before their "breathing" begins to become "shallow," the weight of charge taken becomes much less than normal and pulling power markedly falls off. "Deep breathing" has been secured by reducing the resistance to the escape of the exhaust gases and to the entrance of the fresh gas, in other words, by adopting valves of extremely large area, lifted from their seats very quickly and to an adequate distance, by making use of intake and exhaust piping of liberal area, smooth interior surface and freedom from unnecessary bends and by making the path of the charge entering the cylinders and the exhaust leaving them, as direct as possible. Engines with four valves per cylinder are engines that are sought to be made "deep breathing" in order that the utmost output may be gotten out of a cylinder of given volume and weight. Hardly had designers succeeded in improving the respiratory qualities of engines, as above outlined, when new conditions arose to complicate the situation. Commercial gasoline become so involatile that only at a rather high temperature could it be retained in combustible mixture with air. But if, in order thus to secure effective vaporization, engines must be fed heated and considerably pre-expanded mixture, they cease to be "deep breathing engines" for they cease to inhale cylinderfuls of the utmost weight that the piston displacement ought to hold and they operate more like engines at great altitudes, with considerably reduced output. In a word, if we don't heat the mixture hot enough, the heavy "ends" of the fuel pass through unburned in the exhaust or deposit in the lubricating oil, and if we raise its temperature high enough to insure a dry mixture, the otuput of the engine is likely materially to be reduced, through the restriction of charge weight caused by pre-expansion.

Non-Skid Tread

MALTESE CROSS TIRES

Ribbed Tread

Farmers will find that the extra mileage and the phenominal endurance of Maltese Cross Tires is not a "Just Happened" piece of luck, but that it is a result of steady experiment and years of experience in putting tires together absolutely right. They are an integral part of every Maltese Cross Tire made and sold.

The extravagance of a big guaranteed mileage is apparent to anyone who stops to think. Mileage depends largely on conditions. We claim that with ordinary care Maltese Cross Tires will equal and, in most cases, outwear any tire on the market. Ask any user of Maltese Cross Tires what he thinks of them. Let public opinion guide you in selecting your next tire.

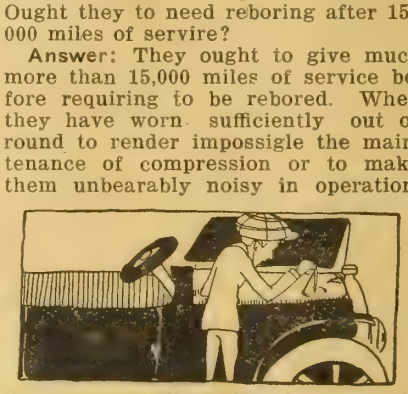
OVALIZATION OF CYLINDERRS

E. B. writes: The cylinderes of my engine are somewhat out of round in the lower half of the bore and the compression is poor. How much out of round ought they to be allowed to become, before they are rebored. Ought they to need reboring after 15,000 miles of servire?

Answer: They ought to give much more than 15,000 miles of service before requiring to be rebored. When they have worn sufficiently out or round to render impossigle the maintenance of compression or to make them unbearably noisy in operation,



they are usually rebored, but it is difficult to give any exact figures as to when to have this operation performed. Unless "piston slap" is known to be present to an annoying extent or insurable leakage past the pistons takes place, reboring may well be longer deferred.

CHOOSING SPARK-PLUGS

A. St. J. writes: The manufacturers of my car strongly advise their customers to use ——— spark-plugs, but I have heard it hinted that this is because the car manufacturer and the plug makers are connected in a business way. Is there any risk in using plugs of other makes?

Answer: We doubt whether any car manufacturer would advise the use of a spark-plug or any other accessory—

other than that capable of giving the best possible results—no matter what business relations might subsist between him and the accessory maker. There is no risk in using other makes of plugs, except that of obtaining less satisfactory ignition results. Very likely you will obtain practically as good results, with plugs of other brands than that recommended. We should, however, advise you to stick to plugs of about the same length and type as those furnished with your engine.

CHANGING OPERATOR'S POSITION

D. V. asks: Is it possible to change the steering of an old car from right hand into the modern lefthand arrangement?

Answer: We suppose that it would not prove impossible to make such a change as this, but it would be utterly impracticable to undertake it. You would have to build the car almost completely over and the expense would be enormous and out of all proportion to the results obtained.

HOW MUCH TO HEAT THE INTAKE

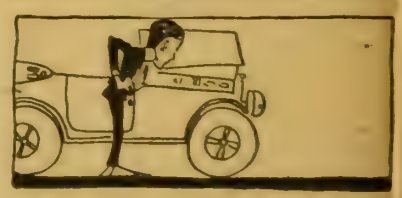
It Depends Upon Conditions And Too Much Is As Bad As Too Little

It is now generally taken for granted that, with fuel as involatile as it is at present, the intake piping of every engine requires some artificial heat applied to it—at times at least. Hot water is pretty well admitted to be too slow in action and insufficient as to temperature and exhaust gas is almost universally used to furnish heat to a "hot spot" or restricted portion of the intake system, to the carburetor mixing chamber or to the intake manifold as a whole. This is all very well, but it is evident that the supply of heat should vary with conditions of use. In extreme winter weather, with the carburetor air very cold, and the car most likely used for runs too short to establish maximum water temperature values, a more liberal supply of manifold heat should be furnished than during intense summer weather, when air is hot and average conditions of use favor early established and long continued maximum circulating water temperatures. The fact is that there should be provided means for conveniently regulating the amount of manifold heat furnished, in proportion to current requirements. In some designs the heat supply is arranged to be at a maximum when the engine is idling and is shut off automatically whenever the throttle is fully opened on the theory that pre-expansion will thus be avoided at times when full power is required. With most intake heating arrangements, however, there is no means of regulation, the heat being either entirely off or fully on. With many there is no means of shuting it off. Unfortunately too, there is no way by which the operator can decide whether he is obtaining too much or too little heat and it seems highly probably that automatic thermostatic control of mixture temperature will solve this problem, just as thermostatic control has solved the water temperature problem. A thermostat, subjected to the temperature of the mixture in the manifold, can be used to increase the heat supply whenever mixture temperature is below that found to be most generally advantageous and to reduce the heat supply when opposite conditions prevail. Until such a device comes into common use, the operator will have to use his best judgment erring, if at all, upon the side of excessive rather than deficient heat supply.

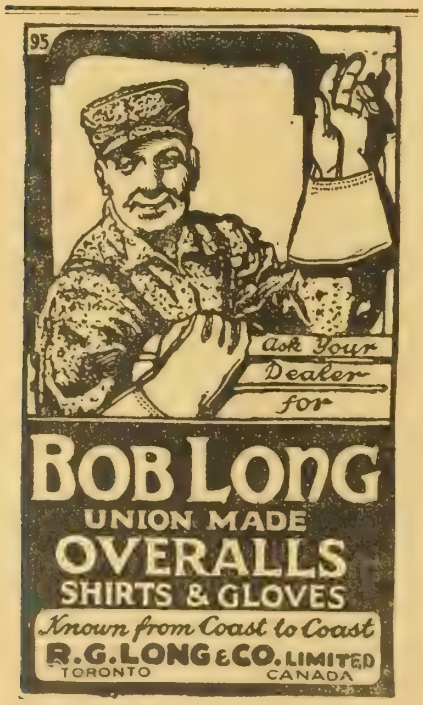
TWO CYLINDERS FAIL AT LOW SPEED

J. A. M. asks: Cylinders 5 and 6 of my engine do not work at low speed. I am quite sure that the trouble is in the carburetor. What adjustments should I make to overcome this? Should the mixture be thinner or richer?

Answer: It is not at all clear to us that this is a carburetor trouble. More



likely it is due to faulty manifold action or to air leaking into these two cylinders. If the former, it may be that more heat is required by the manifold to prevent the condensation of gasoline in it. If the latter, the most common points where air may leak in and dilute the charges are around the loose stems of inlet valves, at the connection of the inlet manifold branch with the intake port and



around spark-plugs. Are you sure that the spark-plug gaps are correctly adjusted? If your carburetor adjustment were much out of the way, the other four cylinders would be likely to miss. You can probably make 5 and 6 fire by enriching the mixture but this may make your engine very wasteful at all speeds. Ifr after running at low speed the plugs of 5 and 6 are found sooted, the mixture should be made leaner instead of richer.

"BRINGING UP" LOW BATTERY CELL

E. B. writes: I use a rectifier to charge my battery. Sometimes I find one cell is more discharged than the other two, according to the hydrometer test. How can such a cell be brought up to strength?

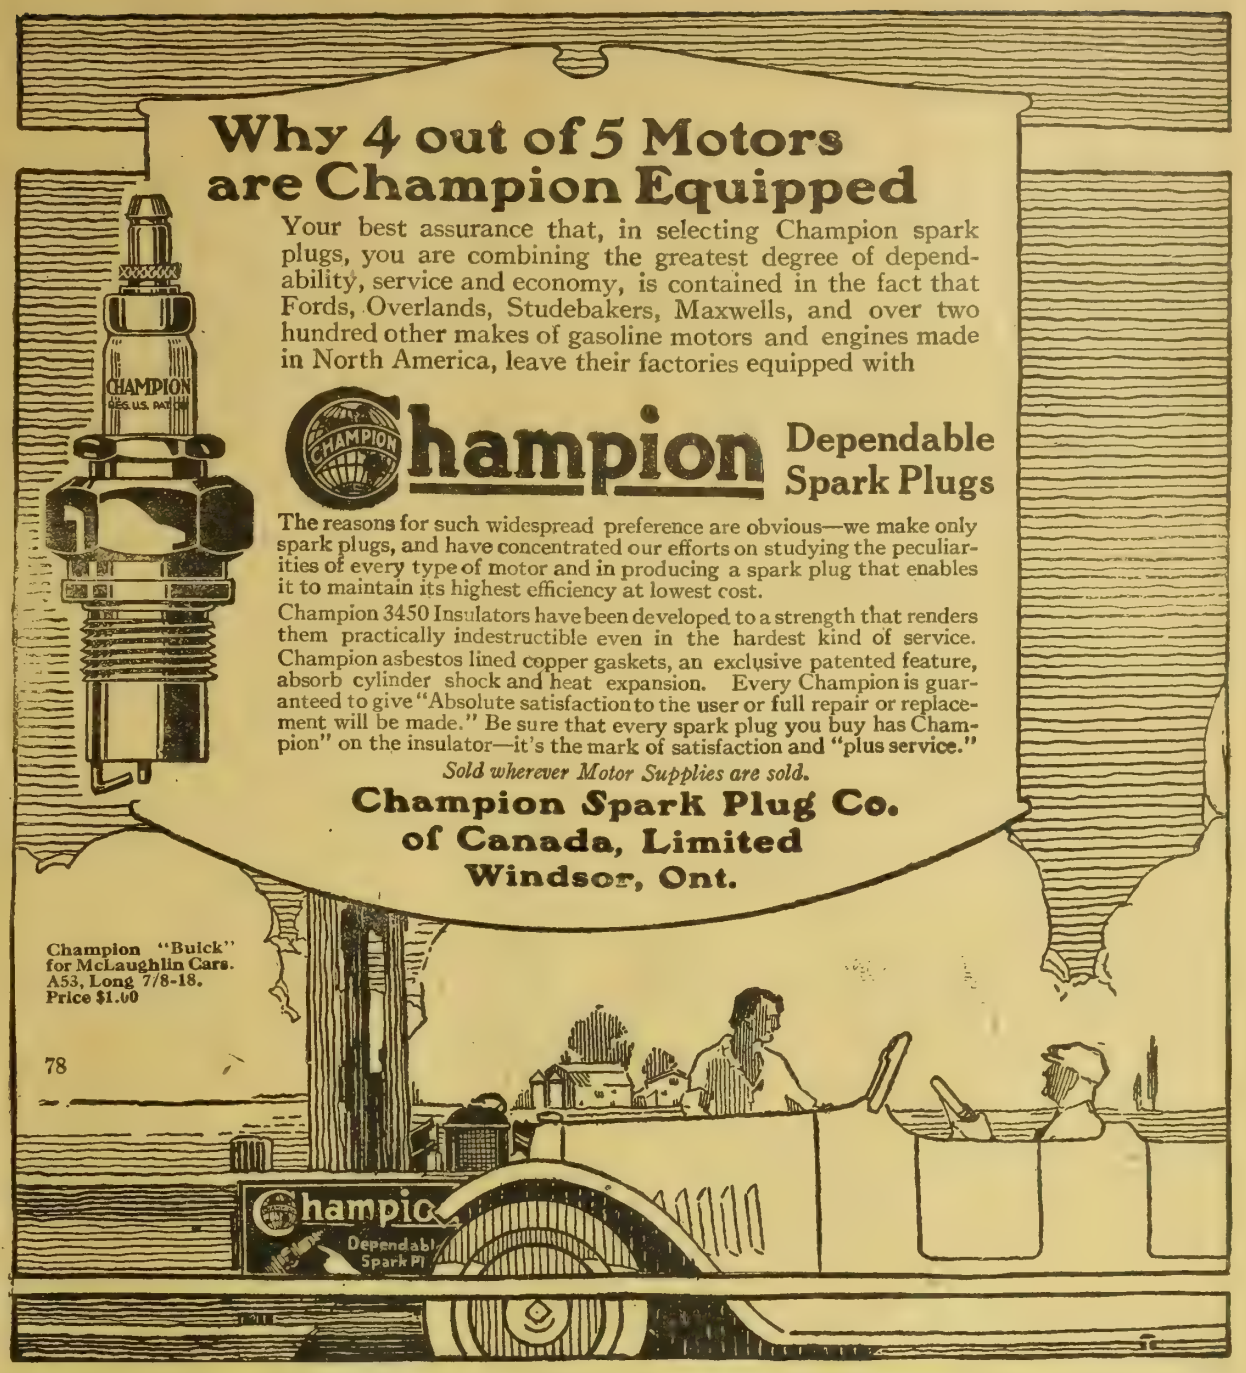
Answer: If you can make good contacts with the lead connecting lugs of the weak cell, you can charge it alone from your rectifier without charging the other cells, using extra resistance, in order to keep the current at its correct value. There is no

special harm, however, in charging the whole battery, at a low rate, until the low cell is brought up to standard, even though the other two cells are being overcharged. If a particular cell of the three tends habitually to become discharged, you may suspect internal short-circuiting and you may as well have it inspected and put into order as to be continually bothering with recharging it.

THE PASSING OF THE PLATINUM POINT

The Tungsten Point Has Generally Superseded It

Motorists have always been accustomed to think of the breaker points of ignition apparatus as composed of platinum or platinum iridium alloy, but even prior to the war, tungsten began to supersede these metals. During the war and up to the present time, interference with the Russian platinum supply and the taking over, by government agencies, of almost the entire available supply of this metal, have made platinum contact points very scarce and almost prohibitively expensive. Fortunately, tungsten has been available and is, at present, almost universally used in the battery ignition systems now so generally employed. In all probability we might as well say "good bye" to platinum points, for tungsten points serve remarkably well and possess no disadvantages that warrant the use of the more expensive metal. In fact, the melting point of tungsten is higher than that of platinum, making tungsten points more proof against fusing and sticking and they are also harder and more resistent to mechanical wear than ordinary platinum points. It has long been customary for motorists to give their platinum points considerable attention as to cleaning, smoothing and truing up, but the tendency is, with the harder and less expensive tungsten points, rather to let them take care of themselves and to renew them (together with the parts that carry them) when they wear away or become troublesome. Silver also has come to be largely used for the contact points of control devices, used in electrical systems, as a substitute for platinum, so that verp little of this precious metal is required in the battery systems as now installed. For magneto breaker points, platinum seems still to be almost essential.



Why 4 out of 5 Motors are Champion Equipped
Your best assurance that, in selecting Champion spark plugs, you are combining the greatest degree of dependability, service and economy, is contained in the fact that Fords, Overlands, Studebakers, Maxwells, and over two hundred other makes of gasoline motors and engines made in North America, leave their factories equipped with
Champion Dependable Spark Plugs
The reasons for such widespread preference are obvious—we make only spark plugs, and have concentrated our efforts on studying the peculiarities of every type of motor and in producing a spark plug that enables it to maintain its highest efficiency at lowest cost.
Champion 3450 Insulators have been developed to a strength that renders them practically indestructible even in the hardest kind of service. Champion asbestos lined copper gaskets, an exclusive patented feature, absorb cylinder shock and heat expansion. Every Champion is guaranteed to give "Absolute satisfaction to the user or full repair or replacement will be made." Be sure that every spark plug you buy has Champion" on the insulator—it's the mark of satisfaction and "plus service."

INCREASED POWER FROM ENLARGING CYLINDER BORE

N. S. P. writes: I have an old car, the engine of which has worn its cylinders so much out of round that they require reboring and new pistons, and it has occurred to me that I might as well make the bore considerably ggreater, fit larger pistons and obtain quite a good deal more power. My mechanic says the cylinders are thick enough to give me 3-16-inch addition to the original 3 ¾-inch bore. Will

this increase give me proportionally more power without necessitating the maaking of anp other changes??

Answer: This change will increase the piston displacement about 10 per cent. and should increase the engine's pulling power, at low speed, in about the same ratio. We doubt, however, whether it will increase its maximum horsepower very materially for, at high speed, the valves, ports, intake piping and carburetor may not possess sufficient surplus capacity to take care of the increase in gas demand and the added weight of the larger piston (unless some light material is used) will tend to reduce the maximum speed at which the engine can safely be run. Enlarging the bore to this extent we regard as risky, unless you know that the metal in the cylinder walls is amply thick at all points.

PISTON CLEARANCE

E. .B. .asks: In fitting new pistons how much smaller should their diameter be than that of the cplinder bore?

Answer: Practice varies somewhat in this regard, but a common rule applying to cast iron pistons is to allow a clearance of two one thousandths of an inch at the head end and of one-half thousandth inch at the skirt end for each inch of piston diameter. For instance, a cast iron piston of four inches diameter should measure 0.008 inch at the head end and 0.002 inch at the skirt end less than the bore in which it is to run, these measurements being made with the parts cold.

HOW MOISTURE BOTHERS IGNITION APPARATUS

J. A. M. asks: In cold weather, does moisture sometimes collect on parts of the ignition system and cause trouble? If a car fails to start, where should one look for difficulties due to this cause?

Answer: Sometimes, when the air in a garage is damp and the temperature suddenly drops, moisture collects over all parts of a car stored therein. It may form upon the make and break and distributing mechanism of the ignition system, and may even freeze thereupon, causing the former device to work sluggishly or to fail to make contact and the latter device to short-

circuit. These parts of the system should be inspected, to see if they work properly and moisture wiped off them in case starting truobles are experienced in cold weather. Sparkplugs also sometimes become short-circuited by moisture and resuire to be wiped dry.

Minard's Liniment Co., Limited.

Gentlemen—I have used MINARD'S LINIMENT on my vessel and in my family for years, and for the everyday ills and accidents of life I consider it has no equal. I would not start on a voyage without it, if it cost a dollar a bottle.

CAPT. F. R. DESJARDIN.
Schr. Storke, St. Andre, Kamouraska.

MARKETS.

CHARLOTTETOWN

Beef—Dessed carcass, ox 22c, cow 20c.
Veal—Dressed carcass, 16c.
Hogs—None offering.
Lamb—Dresser carcass, 30c.
Mutton—Dressed carcass, 24c.
Beef Hidees—40c to 45c per lb.
Sheep Skins—60c to 70c each.
Calf Skins—70c lb.
Potatoes—Practically off the market, nominal pricie $1.00 bushel.
Carrots—None except new crop in retail stores.
Turnips—None.
Parsnips—None.
Oats—90c to $1.00 per bushel.
Cornmeal—$4.75 per bag.
Bran $2.40 to $2.50 per bag.
Oatmeal—$5.50 to $6.00 per bag.
Middlings—$2.50 to $2.60 per bag.
Cotton Seed Meal—None.
Oil Cake—$4.50 to $4.75 per bag.
Buckwheat—None.
Ontario Flour—$12.25 per bbl. in wood.
Manitoba Flour—$12.50 per bbl. in wood.
Chickens—None except in retail way.
Fowl.—None except in retail way.
Turkeys—None.
Geese—Nono.
Butter, creamery—55c to 60c.
Butter, Dairy—42c to 45c.
Cheese—25c to 27c.
Eggs—44c to 45c per dozen.
Hay—Old pressed, $23.00 to $26.00 per ton.
Etraw—Old pressed, $12.00 to $13.00 per ton.
Crops on Prince Edward Island look very fine and prospects are good for a good harvest.

COUNTRY PRODUCE

Montreal, Aug. 23.—The receipts of eggs locally today were 1,355 cases, against 1,582 for the same day last week, 1,113 for same date a month ago and 1,165 for the same date a year ago.

The receipts continue to grade better, and the supply of better eggs is, in consequence, larger. The demand for the best eggs is active and prices continue firm. There is nothing new to note in the situation.

Strictly new laid eggs.....62c to 64c
Selected stock .....55c to 58c
No. 1 stock .....50c to 52c
No. 2 stock .....43c to 45c

The better arrival of ducklings on the local market has caused a decline of about 2c to 3c per pound in the price, and fresh killed ducklings are quoted today at 40c per pound. On the other hand, the quotation for Brome Lake ducklinigs is at 48c per lb., against 46c to 48c previously quoted. The high price of eggs is keeping the farmer from marketing his poultry, and fowls are not arriving on the market, with the result that the decreasing storage stock is causiing an advance in the price, today's quotations being at 45c per lb., against a previous quotation of 30c to 36c. Storage geese are not finding a big demand, and the price rules easy at 28c to 30c per lb., but turkeys are getting scarcer and, as there will not be any fresh killed turkeys on the market until some time in October, it looks as if they will soon be off the market. Today's prices are given at 50c to 53c per lb., according to quality, against 48c to 50 perviously quoted.

There is nothing new in the market for honey. Dealers are still holding back from buying the new crop, so that the main supply on the market continues to be last year's left-overs, which is selling at 20c per lb. for buckwheat and 25c per pound for white clover. Local firms are still of opinion that they should get the abundant new crop at 18c per lb., but the producers are asking generally 25c for buckwheat and 28c for white clover.

The arrivals of potatoes on the local market are erratic. Some days there is a plentiful supply and the price is weak accordingly, and on other days there is a scarcity and the price is firm accordingly. Today's quotations were at $2.75 per bag of 90 lbs. Only the Quebec potato is on the market. The New Brunswick crop is not expected for a while. The demand today was active.

DAIRY PRODUCE TRADE

Montreal, August 23.—The receipts locally today were 764 packages, against 695 for the same day last week, 5.669 for the corresponding date a month ago and 1,361 for the corresponding date a year ago.

The butter market was firm today at Monday's quotations, and, despite the high price, there appears to be as much butter consumed as during this time a year ago. Supplies are moving freely into the hands of consumers, and although local firms state that they see no reason for the high prices, yet so long as the price of cheese rules high, butter prices are likely to be maintained.

We quote wholesale jobbing prices as follows:

Pasteurized creamery...55½ to 56c
Finest creamery .....55c to 55½c
Fine creamery .....54¼c to 54½c
Finiest dairy .....49c to 50c

The receipts of cheese locally today were 20,280 packages, as compared with 22,315 for the same day last week, 10,600 for the corresponding date a month ago, and 6,622 for the corresponding date a year ago.

There is no change in the cheese situation. Local consumption demand is quiet, and the export demand is taking practically all the offerings.

The Canadian Cheese Export Committee will pay the following prices for all cheese delivered to warehouse, Montreal:

No. 1 grade, per lb.....25c
No. 2 grade, per lb.....24½c
No. 3 grade, per lb.....24c

New York, Aug. 21.—Butter, firm. Receipts, 8,353 tubs. Creamery, higher than extras, 56½ to 57c; creamery, extras, 92 score, 55¾c to 56c; firsts, 52½c to 55½c; packing stock, current make, No. 2, 46c . Cheese, irregular. Receipts, 1,339 boxes. State, whole milk, flats, current make, special, 30½c to 31c; do. average run, 29½c to 30c; State, wohle milk, twins, current make, specials, 31¼c to 31¾c; do. average run, 30c to 30¾c.

MILLFEED AND ROLLED OATS

Montreal, August 23.—As there is practically no millfeed on the market and as the demand is extremely heavy the price is firm. Millers are not doing a very large business owing to the scarcity of supplies mentioned. Quotations on bran, in 150-lb. bags, for mixed car lots, were $48 per ton, and for shorts, $50 per ton, the prices to include bags, delivered. Millers are quoting $6 per ton less, in mixed car lots, ex-tractk.

In the general rolled oats market there is a scarcity of supplies, although locally the supply on hand appears to be equal to the demand. The enquiry for rolled oats does not begin actively until much later in the year so that at the present time the market is not activefi although the high price of oats is keeping the price of rolled oats up. Today's sales were made at $4.95 to $5.25 in jute bags, and at $5 to $5.25 in cotton bags..

LIVE STOCK MARKETS

Toronto, August 23.—Following yesterday's big run of live stock at the Union Stock Yards, today's market was rather dull. However, there was a good demand. The cattle prices were steadier, although the buyers complain that there is too much common stuff. The inferior grades are now due to drop slightly on account of the reduced price of hides. The choice animals still bring good prices and choice milkers and springers are being sold at from $140 to $160. The sheep market also was firm, and the demand steady. Owing to the insistent pressure upon the part of the packers, hogs again took a considerable drop this morning. Yesterday hogs, fed and watered, were selling at $23.25 per cwt., today they only brought $22.25, a drop of $1 per cwt. Predictions are to the effect that this figure may even be lower. Receipts for the day at the Union stock yards were 606 cattle, 146 calves, 560 hogs and 892 sheep. Quotations:

Heavy steers, choice	$13.50	to	$14.50
Choice butcher	11.00	to	12.00
Do. medium	8.00	to	9.00
Do. common	7.00	to	7.75
Heifers, good to choice	11.50	to	13.00
Butcher's cows, choice	10.00	to	11.00
Do. medium	8.25	to	8.75
Bulls, choice heavy	10.00	to	11.00
Do. good	9.00	to	9.75
Do. light	8.00	to	9.00
Do. canners	5.00	to	5.75
Stockers, 800 to 900 lbs.	9.00	to	11.00
Do. liight mixed, 650 to 750 lbs.	7.50	to	8.00
Grass Cows	7.00	to	8.00
Milch cows	75.00	to	100.00
Spring lambs	16.50	to	17.50
Sheep, light	9.00	to	10.00
Yearlings, lambs	12.00	to	13.50
Heacy Sheep & bucks	8.00	to	8.50
Calves	18.00	to	22.00
Hogs, fed and watered, bid			22.25
Do. off cars			22.50
Do. f. o. b.			21.25
Do to the farmers			21.00

THE PROVISION MARKET

Montreal, August 23.—The undertone to the market for live and dressed hogs continues weak at the decline in prices noted yesterday, although no further reduction in prices has been made. The demand for both live and dressed hogs is slow. Sales were made yesterday at $22.50 to $23, per central for live selects, $27 for sows and $25 for stags.

There appears to be no diminution in the demand for all kinds of hog products, and supplies of hams and bacons, are moving rapidly into consumers' hands. The supply of bacon on hand is not keeping up with the demand, and prices rule firm accordingly. Sales of Windsor boneless bacon were made today at 56c per pound, and of breakfast at 50c per pound. Smoked hams are moving well, although not quite so actively as bacons. Small hams weighing from 8 to 10 lbs. sold today at 46c per lb.; medium hams weighing from 10 to 15 lbs. sold at 44c per lb., and heavyweights weighing up to 20 lbs. and over sold at 40c per lb.

There is no change in the market for barrel pork. Supplies on hand are quite ample to fill all reqirements and more. Quotations on short cut and on clear fat back are unchanged at $60 per barrel.

There is an active demand for sausages and sales in a wholesale jobbing way were made today at 27c per pound.

The supplies of lard on hand are not large considering the heavy demand, and there is no sign of weakness in the price, despite the fact that prices for hogs have declined about 2c per pound in the past couple of weeks. Sales of Canadian pure lard were made today at 36c per lb. in 20-lb. wood pails. American compound lard is selling at 27½c per pound in 20-lb. wood pails, and shortening at 31c in 20-lb. wood pails and at 32c to 34c in one-pound blocks.

The receipts of provisions today were 197 packages of meats, 1,115 packages of lard, and 209 live hogs.

Chicago, Aug. 21.—Provisions were unsettled, an early decline being followed by a rally on strong demand which moved prices above yesterday's close. Later fluctuations were in narrowest limits and the final figures were about the top point. Reports of the flating of a German loan to be spent for food products were credited with being a factor in the advance. Prices finished the day at 50c to $2 higher. Future quotations were:

	Open	High	Low	Close
Mess Pork per bbl.:—				
Sept	$41.50	$43.00	$41.50	$43.00
Oct.	39.59	40.50	39.00	40.00
Lard, per 100 lbs.:—				
Sept.	28.00	28.80	28.00	28.80
Oct.	27.70	28.50	27.70	28.50
Short ribs, per 100 lbs.:—				
Sept.	23.65	24.30	23.65	24.30

Cash prices closed—Pork nominal. Lard, $29.06. Ribs, $24 to $24.75.

THE BALED HAY MARKET

Montreal, August 23.—The arrivals of new crop on the local market are increasing, but as the demand is limited, there is not much business doing, local firms are still quoting $24 per ton, and opinions are that prices will hate to come a little lower if business of any account is to be done. There is still a fair supply of old crop hay on the market, for which dealers are asking $27 to $28 per ton for good No. 2 timothy; $25 for No. 3, and $22 to $23 for clover and clover mixed.

Winnipeg, August 21.—October oats closed 1½c higher, December 1⅝c higher, and May 1⅜c higher. October barley closed 1⅜c higher, and December 2¼c higher. October flax closed 2c lower.

Winnipeg's fluctuations in grain prices were as follows:

	Open	High	Low	Close
Barley—				
Oct.	$1.30	$1.31	$1.30	$1.31
Dec.	1.24	1.26	1.24	1.26
Oats—				
Oct.	0.84¾	0.86½	0.84¾	0.86½
Dec.	0.81⅜	0.82¾	0.81.3	0.82¾

MENDING BAGS

A quick and very easy way to mend bags, and one which the men can do as easily as the women, is as follows: Turn the bag wrong side out, cut patches large enough to cover well the holes and weak spots. Make a medium thick paste of flour and water, spread on patch, and press with a hot iron. The patches will last as long as the bag and can be put on in less time than it takes to sew them.

WALLACE MACHINE WORKS, Ltd. - - Sussex, N. B.

Every Young Farmer in the Maritime Provinces

SHOULD WRITE TO TRURO FOR A

FREE Copy of the Calendar of Agricultural College, Truro, N. S.

The College opens Nov. 4th next. Tuition is Free

A complete course is offered in all branches of Agriculture and the related sciences as well as English, Mathematics, etc.

An ordinary school education, plus farm experience qualifies for entrance. The age of former students varies from 16 to 35.

The course lasts two years at the conclusion of which students are awarded the Associate Diploma of the College. Graduates may complete their B.S.A. course at Guelph or MacDonald Colleges. Previous graduates have from year to year stood at the head of their classes at these institutions.

For further information write

Clearing Sale of Shorthorn Cattle

Am offering for sale my herd of pure bred registered Shorthorn cattle. These cattle range in age from 7 years to 3 years, or a little less, with one bull calf two weeks old, and are all fine in type and color.

I have also exceptionally good grade cattle of various ages for sale. All will be sold at a reasonable price and offer an unusual opportunity to anyone desiring to start a herd of choice stock or to renew an old herd.

J. E. HETHERINGTON, - Codys, N. B.

FOR SALE !

Two excellent Guernsey bulls from good stock, will be sold reasonable if taken at once.

SARAH E. M. SMITH,
Woodwards Cove, Grand Manan, N. B.

FIRSHADE FARM
DUAL PURPOSE SHORTHORNS

Present Offering:—Two Bull Calves

No. 1.—Son of Daisy Lodge, R. O. P. 11,638 lbs. milk, 480 lbs. fat. This cow led the four-year-old class in the Canadian Record of Performance.

No. 2.—Son of Queen Charlotte. She as a two-year-old has a R. O. P. of 7224 lbs. milk, 316 lbs. fat. This cow stands eighth in milk and sixth in fat production in the two-year old class.

The sire of these calves is Nivelle, whose dam as a two-year-old has a R. O. P. of 5496 lbs. of milk, 240 lbs. fat in 295 days.

P. R. L. FAIRWEATHER, Rothesay, N.B

Willow Glen Shorthorns !

Thanks to Maritime Farmer Advertising I have disposed of the following individuals from my show herd: 1st Prize 3 year old cow; 1st Prize 2 year old heifer and 1st Prize Senior Heifer to J. M. Laird & Son; 1st Prize Junior Heifer to D. C. McNutt, all of Prince Edward Island, and 1st Prize Bull Calf to Roy B. Pipes, Amherst, N. S. All my bulls are sold. I still have a few heifers for sale, sisters and dams of prize winners.

Auto Tires $17.50

Fine non-skid tire for small cars, size 30 x 3½, fully guaranteed for 3500 miles

The Maritime Farmer begs to announce a substantial reduction in the price of non-skid tires for small cars, Fords, Chevrolets, Maxwells, etc. They are FIRSTS, fully guaranteed and we will sell them to you, provided you are a paid-up subscriber to the Maritime Farmer for $17.50 f. o. b. Sussex. Plain tires for $16.25, fully guaranteed for above mileage. Tubes for same size tire $2.90. These goods are all A1 stock and are made by a well known tire house. Of course these prices are for spot cash with order. The Maritime Farmer was able to take advantage of the recent break in the market and its large buying capacity to get you the benefit of this substantial cut in price. IT'S THE BEST BUY IN CANADA Today. Write the Auto Department, Maritime Farmer, Sussex, N. B.

A VERY VALUABLE BOOK

The Veterinarian, by Charles J. Korinck, V. S., is a work on the afflictions of horses, cattle, sheep, swine, poultry, etc., which every farmer should have in his home. The story of how treatment can best be administered is told in simple every-day English that any person can understand. The methods suggested by Prof. Korinek are simple and easily followed. The book will cost you seventy-five cents, postage paid. It may be the means of saving you as many dollars in the near future. How many men are there who meet trouble by writing to the Maritime Farmer or some other paper for information which will be found in the Veterinarian? It is strongly bound in cloth, has serviceable illustrations and is well indexed. Seventy-five cents will bring it to you.

HOLLOW POTATOES

Many of my potatoes last year were hollow, and, therefore, objectionable from the cooking standpoint, especially for baking. Is there anything that can be done during the growing season to prevent potatoes from becoming hollow?—J. B. S.

Ans.—Cavities in potatoes are caused by rapid growth. The cells towards the outside of the tuber, being young, are capable of rapid growth and division. Those toward the centre having attained their full growth are not capable of such development. The stress caused by rapid growth of the potato tends, therefore, to rupture the tuber at the centre. This is the reason why it is always the largest and finest potatoes which are found to be hollow. The injury is not so serious, however, as it would be if it affected the outside. The only way to prevent it is to discourage rapid growth, but this would interfere with the yield of the crop; it cannot be resorted to without loss.

Chester White Pigs for Sale

Book your orders now for Chester White Pigs from four weeks upward. Pairs furnished that are not akin.

W. A. ERB, SUSSEX, N. B.

ELMHURST STOCK FARM

Clydesdale Horses, Hereford Cattle, Leicester Sheep.

We are offering 4 Bulls fit for service, 9 to 12 mos. old. They are good thick, straight bulls fit to head a herd in any county. Prices moderate. We have Rams and Ewes for fall delivery. Write your wants, we can suit you in quality and prices.

William O'Brien & Sons, Windsor, N.S.

FOR SALE !

Several young bulls of serviceable age and youngsters. Well bred and good individuals. Prize winners at our recent show. Their dams won 1st, 2nd and 3rd in the ring of aged cows; also 1st and 2nd in the dairy test, 1st in heifer class and st in grade cow, competing against all breeds at our late show at Charlottetown. with an average fat of nearly 4 per cent. We will send photos of these young bulls and their dams to any prospective buyers. For quick sale we have priced them at from $50 to $125.

BARN VENTILATION

By L. J. Smith, B. S., Professor of Agricultural Engineering, Manitoba Agricultural College, Winnipeg, Canada

In newly settled districts, the farmer must of necessity erect inexpensive and more or less temporary buildings to shelter his stock. As he becomes better settled in his new surroundings and prospers, the natural step is that of securing better buildings, not only for the sake of his stock, but for his own convenience and comfort while caring for them.

There was little need for a scientific plan of ventilation for the temporary barn. Loosely constructed and smaller in size than our modern barns, these buildings have enough air leakage to supply the stock with fresh air—often in windy weather far too much ventilation for man or beast. With the advent of the modern well-built barn, stock are warmly housed. It is found, however, that more than a warm barn is necessary for the maintenance of the health of those animals that are shut in for at least the greater portion of the winter season. Three important items must not be overlooked, namely: good lighting, a sanitary interior, and some means of providing ample ventilation under all conditions, in still and mild winter weather as well as when it is cold and windy.

Sanitary Considerations in Barn Building

Abundance of light and ventilation must be had, even at the expense of heat, in the stable. Windows should be fairly small and uniformly distributed, rather than very large and few in number. A very good practice is to have the studding on two foot centres, and to put narrow windows between the studs. They should be located high enough to let the sunlight well into the centre of the barn, Any cold air leaking in around the windows under these conditions, will have time to mix with the warmer air at the top of the stable before reaching the stock. Putting windows in high also reduces glass breakage to a minimum. There should be one square foot of glass to every twenty or twenty-five square feet of floor space. The glass should be cleaned at least twice a year, in order not to cut off sunlight. This does not mean a painstaking washing and drying of windows, such as is done by the housewife, but merely a washing to get off the dust and cobwebs. No modern barn should be without storm windows.

The interior walls should be smooth so as to be easily brushed down, and should be whitewashed both for sanitary purposes and to prevent absorption of light. In many Manitoba barns the stables are whitewashed twice a year. The stable floors should be of concrete to afford easy cleaning and cleansing, and to prevent absorption of liquids.

Why Ventilate Barns

Barn ventilation is necessary for various reasons:—to remove dust in the air, impurities from the skin, vapors and odors arising from the manures, to carry off the carbonic acid gas breathed from the lungs of the animals, and to replace it with pure outside air; to keep down the amount of moisture in the air in the barn; to keep the air in circulation; to regulate the temperature of the stable; to remove germs; and to prevent the rotting of wood, and the rapid deterioration of stable fittings and paint. If one animal in a stable has tuberculosis, the chances are strongly in favor of other animals contracting the disease unless the stable be flooded with sunlight, and kept well cleaned, and unless the air is changed frequently.

It is scarcely necessary in these enlightened days to spend time defending the principle of ventilation; but it might be of interest to discuss briefly the results of investigations along this important line.

Experiments have shown that animals can not only live, but apparently thrive, in closed spaces, affording none but accidental ventilation. These experiments, however, have not been conducted long enough to prove the point. A few month's test is not sufficient foundation for a conclusion as to what is the proper foundation for a conclusion as to what is the proper amount of ventilation for all the winter months of the life of the stock. It is possible for men and beasts to live for a time in insanitary conditions and suffer at the time no apparent ill effects; but continued insantary conditions are sure eventually to lower vitality or to induce disease.

At low temperatures it is possible with no immediate ill effects to breathe over and over the same supply of air until the proportion of the carbonic acid gas in the air is very high. Much of the ill effect experienced in badly ventilated buildings is due. not so much to the rebreathing of the air, as to lack of circulation of air and the high temperatures which make it difficult for the body to maintain its normal temperature. As an example, an electric fan, running in a warm close room, will almost at once relieve the occupants of physical discomfort.

Effects of Poor Ventilation Slow Acting

From the above it might seen that under conditions where the stock has been tested and found in good health, the same air might be breathed for a time without affecting the health of the stock, so long as the temperature of the stable was low. But it should be borne in mind that the effects of poor ventilation are notoriously slow acting. Even tuberculosis may exist without any outward sign. It is better not to take the risk.

Disease Resistance Affected

There is, however, another side to the question of restriction of ventilation. It has been found by tests that while animals might not suffer at the time in appetite and general good health, through lack of fresh air, still restricted ventilation breaks down the capacity of the animals for successfully resisting the disease germs with which they must come in contact from time to time.

In this conclusion, if the tests have been sufficiently extensive to establish the fact, we have without doubt the strongest argument in favor of thorough ventilation. The question should be, not how little ventilation is necessary, but how much fresh air can be given. It is better to have fresh dry air an da cool stable, than a warm stable with moist warm air and dripping walls and ceilings.

Tuberculosis and Ventilation

We know tuberculosis to be a house disease, and we know that those whose life is in the open are least subject to it. We also know that this disease, if taken in hand sufficiently early, can be checked by open air treatment. We know that tuberculosis among animals is a domestic disease from which the wild animals are exempt.

With this knowledge, to neglect barn ventliation is not wise. Indeed, if stock raising is to be successfully carried on in the North-West in the coming years, more attention will have to be given to the problem of ventilation. The time may soon come when the sanitary conditions of barns will be made a matter for government regulation.

Limitations of a Ventilation System

No natural system of ventilation has yet been devised or probably ever will be devised, that will work entirely automatically. Even the best systems of stable ventilation require some attention. Nor is it possible to give the animals in the average barn all the air that is considered necessary, and still keep the inside temperature above freezing durinig the coldest parts of Manitoba's winter months. Still, even during the two coldest months, the temperature rises sufficiently high so that a full amount of ventilation can be had part of the time, and a fair amount nearly all the time.

How a Natural Ventliation System Operates

All natural systems of ventliation work on the same principle. Warm air rises. Out-take flues are provided, passing up through the loft of the barn; the warm air rises through the flues and equal volumes of colder air are drawn into the barn through intake flues arranged along the sides of the stable, and by leakage around the doors and windows, and, in many cases, through the walls of the stable. The principle of ventilation is the same as the draft in the ordinary stove or furnace. In barn ventilation, the animals furnish the heat necessary to caause the circulation of the air.

Factors to be Considered in Regulating Barn Ventilation

The efficiency of the system of ventilation adopted is dependent upon several factors, namely, the position and size of in-take and out-take flues, the smoothness of the inside of the out-take flues and the number of bends in the same, the rate at which the wind is blowing, and the difference in temperature between the inside and outside of the barn. The higher the out-take flues, the greater the draft. Their size must be figured so as to ensure ventilation under most adverse natural conditions. In quiet weather, and in the mild weather at the beginning and end of winter, the air moves at its slowest rate up the outtake flues. The difference in temperature is secured by well built walls, close-fitting doors and windows, and the barn space being well filled with stock.

Flue Construction

The intake and out-take flues must have means whereby the openings may be restricted in extremely cold or windy weather. The out-take flues must be air-tight and smooth inside, and should have as few bends as possible. They should be put in independently of the walls of the barn. In order to work satisfactorily, they must be constructed of two thicknesses of good, dry inch lumber, tongued and grooved, or shiplap, with good building paper between. The tops of the flues must end at least level with the peak of the roof to prevent the wind blowing down the flue and stopping circulation.

A common type of out-take flue construction is where 2x2 inch corner posts are used with the boards nailed crosswise. If desired, a dead air space could be had by nailing one thickness of lumber inside the 2x2's in which case the construction would be a little more difficult. The outside thickness of the flue may be nailed on lengthwise, which will save both in material and time.

Another type of flue construction is where the boards are nailed lengthwise with the flue, thus giving a smoother inner surface.

Out-take flues should not be made too small nor too large. Fifteen to twenty inches square are safe limits;

(ontinued on page 837)

The Chemical Fertilizer Outlook for 1920

Goods will be Cheaper---N. B. will be Looked After by Agricultural Societies United

What will be the price of chemical fertilizers in 1920? It is a question which is being often asked these days. The answer undoubtedly is that all classes of goods will be much cheaper. Just what the price cuts will be the near future should determine. There is this to say of the situation however, that there have been no prices fixed as yet and the market is in a very unsettled condittion. The next few weeks should see definite announcement as to the prices to rule for next season. As usual, the New Brunswick Agricultural Societies United will buy for Agiruclural Societies who desire to obtain chemicals at cost. None of the difficulties which prevailed in 1919 will have to be met. Then phosphates and ammonias had to be bought at different points and this resulted in no end of confusion. In 1920, the N. B. Agriclutural Societies will be able to ship acid phosphate, nitrates, sulphate of ammonia, tankage, potash, etc. from a central point, in car lots, so that it will be very much easier and cheaper for agricultural societies to look after their requirements.

In connection with the fertilizer situation it might be well to mention that the New Brunswick department of agriculture has decided to install several lime stone crushers at central distributing points in the province. This should prove a great boon to the farmers of this province. It is known that the soil of New Brunswick is deficient in lime. Many farmers have been meeting this call by the purchase of basic slag. In future basic slag can be dispensed with where lime stone is available. It is estimated that ground lime stone will be delivered by the department for five dollars per ton or less. This means that every farmer in the province can supply his own basic slag at prices away below those now ruling for that commodity. The acid phosphate can be procured through the Agricultural Societies United in any combination desired. The lime acts as a tonic in the soil and makes available the natural supply of phosphoric acid. Where this is not sufficient, the shortage can be made up by using acid phosphates to any percentage desired. This method will result in a saving of thousands of dollars to agriculturalists in all parts of the province, and the results which will doubtless follow the use of lime stone will surprise those enterprising enough to take advantage of the new order of things.

It is not too early to begin thinking of your next year's supply of chemicals. Societies should get together and ascertain their requirements. One thing that should prove encouraging is the certainty of a big drop in prices, as compared with last year. As to the saving to be made by purchasing through the Agricultural Societies United, there is no question but that thousands and tens of thousands of dollars have been saved by the co-operative method.

For Nova Scotia, the Maritime Farmer will undertake to supply societies with unmixed chemicals or mixed goods, which will make their old fertilizer bills look big. We intend giving farmers in the sister provinces a chance to test out co-operative buying of fertilizers and will mail quotations to every agricultural society in Nova Scotia, within the next month or two. Be on the lookout for them. Ask your secretary about them and if he says they have not reached him, drop us a line and we will tell you how to buy fertilizers and save yourself many dollars. There will be no dealers commision to pay. Unite with your neighbor and get a car lot. Any of the progressive banks of the Maritime Provinces will help you finance the venture. If your banker will not do so, write us and we may have a suggestion to offer. Bankers who are not red hot after farmers business these days are DEAD ONES. Co-operation has been proved in so many directions that it is well to wake up and realize how much it means TO YOU. BEFORE YOU BUY YOUR FERTILIZERS FOR 1920, write the N. B. Agricultural Societies United, Sussex, N. B., or if you live in Nova Soctia, write THE MARITIME FARMER.

Gleanings From Nova Scotia Agricultural College

SCHOOL CHILDREN'S FAIR

Some six years ago the Local Council of Women at Truro, organized an agricultural committee for the purpose of stimulating the interest of children in the growing of flowers and vegetables. The method followed was the holding of a Flower and Vegetable show in the early autumn of each year. Small prizes were offered in a considerable variety of lines, so that almost any garden product that is useful or beautiful might find a place among the exhibits.

At first a dozen or so of children brought flowers and vegetables, the latter often dirty and of uneven size. The movement has grown wonderfully both in the quantity and quality of exhibits, and in popularity as one of the events of the year for the whole neighbourhood. The entries this year number 41 in flowers, 33 in Domestic science and 114 in vegetables. 18 schools are exhibiting, representing a considerable portion of Colchester Co., to which the show is confined.

A magnificent exhibit occupies a place of honour this year from the Maritime Home for Girls, an institution which is well known among the protestant churches of these provinces. This exhibit contains splendid samples of vegetables, flowers, needlework, canned foods and baking. No better testimony could be furnished to the breadth and efficiency of the training in that institution.

The Fair is held in the Agricultural College buildings, and its success is in no small measure due to the tireless efforts of the ladies of Bible Hill, who are more or less associated with the staff. Nothing more wholesome or useful could be done for the school children than this interesting and beautiful competition in gardening, and many of the exhibits would look very creditable in the stalls of our largest agricultural shows.

A SILO FOR 1920

It is not too early to begin making plans, gathering information, and setting one's jaws for a silo next year. The argument for such an institution is so obvious that we need not repeat it again. The two practical steps the average farmer can take to meet effectively the scarcity and high prices in mill feeds are, 1. Improve his pastures. 2. Build a silo and lay in silage. The first largely meets the summer need, the second, the necessities of wintr feeding. Our best silage crop in these parts, the O.V.P. mixture, will yield ten to twelve tons to the acre on good ground, and it makes a highly nutritious food for dairy cows.

The following is an outline of the materials needed and a general estimate of the cost of building a silo which will hold upwards of twenty tons of silage, 23'x12', built of concrete and staves.

6' concrete, 12" thick, cement 8 bbls.	16.00
Staves, 17'x6"x2"	17.00
Dressing Staves	3.00
Roof Lumber and roofing	10.00
Hoops	10.50
Spikes	1.00
Labor on concrete	7.50
Carpenter work	10.00
Other labor	13.00
8 loads gravel, 2 loads filler	10.00
Two coats tar, 10% kerosene	8.00
Total cost	$106.00

It will be remembered, of course, that prices vary in different localities, and fluctuate from time to time, but this will furnish a working basis for calculation.

In erecting a stave silo put up first stave, plumb it all ways, stay it firmly, then bore each stave through about one fooot from each end and all in the middle, with variation enough to avoid the spikes. Bore first with ¼" bit, then half way through with ½" bit. Use 6" spikes and drive home, the heads going half way through each stave. Place three staves together on the ground and spike together so as to form one piece 6"x6". Place two of these pieces so made opposite each other, taking care not to have them come where the doors are to be. Place the edges of these flush with the inside of staves, then they will show 4" standing out from the staves. These will form uprights to put the hoops through at intervals of about 4 feet, the three hoops nearest the bottom being not more than 2 feet apart, because o fthe greater pressure at the bottom. The first hoop should be ⅝ or ¾", the others ½" iron. When coming to doorways put saw cut in one stave and bottom of each doorway, then, when hoops are tightened up place a band across each end of door on outside, boltng these to door with ¼" bolts, one in each stave. Then proceed to cut out doors, bevelling them so that when they are put in from the inside they will be nearly airtight.

If the lower portion of silo is concrete the staves should stand one inch back from the inside edge of concrete. In this case eyebolts of ¾" iron round or its equivalent flat. They should be set in the concrete with lower end bent and a foot down, and with the eye about four inches above the surface, large enough to take a ½" bolt. These eyebolts should stand back three inches from inside edge of concrete so as to stand close to stave to which they are bolted. When putting in spikes care must be taken to avoid the saw cuts for doors.

RURAL PLANNING AND DEVELOPMENT

The last volume that has reached us from the Canadian Commission of Conservation is probably the most valuable yet issued, both because it was written in the midst of the war-consciousness, with a remarkable appreciation of the tendencies which have so rapidly developed since the war closed, and because its main interest is not in money but in men. A sentence or two from the introductory chapter inidicate the main lines of the author's investigation and interest. "Economic loss may be greater as a aresult of leaving some things undone than as a result of doing other thngs extravagantly. . . We share the growing consciousness, which is everywhere apparent, that national prosperity depends on the charcter stability, freedom and efficiency of the human resources of a nation, rather than on the amount of its exports or imports, or the gold it may have to its credit at a given time."

While no part of the volume smacks of the paternalism which officials are too apt to offer as the cure-all, the author insists that there is great need of supervision, not only of the placing of population on the land, but also of the rudiments of sanitation and of general health conditions. He points out that poverty, hoplesseness and degeneracy have too often succeeded the settlement of land which is naturally unfit for cultivation. So long as the speculator is the central figure in the land situation we are in for abuses that are far more reaching than the casual observer can imagine.

Altogether this is a noteworthy book, and deserves careful study. The author, Thomas Adams, is a man of wide experience both in the old country and on this side. He has gathered his data from a broad field. The style is terse and direct, and the volume very well illustrated, not in a light and haphazard fashion, but with a strong array of facts, and with the penetration of an earnest and keen mind.

UNITED FAMERS GETTING IN LINE FOR FEDERAL ELECTIONS

At a recent convention of the United Farmers of New Brunswick resident in Carleton and Victoria Counties, T. W. Caldwell, of Florenceville, was selected to carry the Farmers banner at the next Federal election for the Carleton Victoria riding.

Mr. Caldwell is the President of the United Farmers of New Brunswick, a public spirited farmer of good repute, appearance and address—the type of man any body of men should be proud to support and the kind of man the Maritime Farmer would like to see elected in every farming constituency in the Maritime Provinces.

The Maritime Farmer is not a political paper in character but we would like to see a clean, intelligent farmer nominated and elected by each and every electoral district in Canada, where farming is the main and most promiment industry. Too long have constituencies of this kind been represented by devotees of some other calling.

The farmers of Canada are coming into their own. They are fast learning to realize the magnitude and importance of their profession. Too long, it could be truthfully said, "farmers will not stick together." We trust that when a farmer candidate is in the field in future elections no matter what his political creed may be, that it will be said when the votes are counted and the results published. "the farmers stuck together and elected their man."

New Brunswick Fruit Growers' Orchard Field Day

That New Brunswick can grow certain varieties of apples that are second to none of their kind in all Canada, has been and is being repeatedly demonstrated by not a few of the live orchardists of the province. Scattered here and there along the St. John River Valley and in other favored parts of the province, are orchards that are as neatly kept and as skillfully tended as the best in any fruit growing section of Canada. The owners and keepers of these orchards have not only been working in their own best interests, but have also helped other men throughout the province who have joined with them in the organization of the New Brunswick Fruit Growers' Association, and who pay attention and strive to practice some of the modern ideas in fruit growing that are frequently propounded by the more progressive and successful members, and the speakers procured to lecture on the various problems that confront the orchardist.

A. G. Turney, the provincial horticulturist has been untiring in his efforts to place fruit growing in New Brunswick on the plane which it should rightly occupy. The respective fruit growers recognized Mr. Turney's ability to help their cause and they have from the time of his appointment reposed well merited confidence in his advice. They made him secretary of their Association and in that capacity the various members of the Association has in many ways profited by the various activities which Mr. Turney has from time to time introduced as part of the working machinery of the organization.

Hon. J. F. Tweddale, the Minister for Agriculture has also very materially assisted the Association by listing it on the schedule for annual grants of money that will help the officers of the Association to put over the top some plans for future and more rapid development.

One of the features introduced this year was an Orchard Field Day, which was observed on August 28th. In addition to the regular members of the Association, the various members of the staff of the Department of Agriculture, the Boards of Trade of Fredericton and St. John, and representatives of the press were invited to be present at the proceedings, which included an auto trip to the best orchards in York, Sunbury and Queens Counties, and a visit to the Experimental Farm, Fredericton.

About one hundred fruit growers and their interested friends enjoyed the outing and profited by what they saw in and heard in the various orchards which they visited. Various growers have various ideas as to the best methods to pursue in orchard management. One may excel along one particular line, another may excel along another line. The idea of the Field Day was to give all hands a chance to see the best ideas of the respective growers and help them to form ideals towards which they may aim in their own every day orchard practice.

The St. John Board of Trade conducts an orchard at Brown's Flats on the St. John River, which is coming along nicely, and consequently the Board is very much interested in fruit growing and sent a strong delegation to the Field Day proceedings.

At the Tamilson orchards at Nashwaaksis, York County, Mr. A. C. Parker gave a demonstration of apple packing and Inspector Potts of St. John outlined the requirements of the fruit marks act and also supplied information as to grading.

An appetizing luncheon was served at noon on the Experimental Farm, after which the young orchard was inspected unde rthe guidance of Superintendent W. W. Hubbard. The party called upon T. H. Estabrooks and spent a pleasant few minutes looking over his beautiful farm near Oromocto. They then proceeded to Burton in Sunbury county, where the holdings of the St. John Valley Fruit and Land Company were inspected. There they saw thousands of young trees in the nursery and the manager, Mr. Fillmore, explained the process of budgrafting. The trees in this orchard are well laden with fruit. R. D. W. Hubbard and others have very promising orchards at Burton, but owing to lack of time the party was unable to visit them. The next visit was pai dto the orchards of W. P. and F. L. Fox and of the Cossar Farm below Gagetown, Queens County.

The Fox orchard is in splendid shape with an excellent crop. Here Mr. Geo. E. Sanders of the Dominion Entomological Division gave an instructive talk on Orchard Spraying. Sample trees were shown on which spraying tests had been conducted. The proprietors of the Fox orchards are now busily engaged in erecting a modern packing house for handling their fruit. The final visit was to the Cossar Farm, which proved a source of great pleasure. From this point the party disbanded. The St. John delegation headed for St. John, while the Sunbury, York and other delegates who had come by train and otherwise to Fredericton, headed for home by the up-stream course.

All hands were delighted with the scenic beauty along the St. John and the magnificent possibilities in orcharding which the trip disclosed, and loud in their praise of the courteous treatment accorded them by Mr. Turney and his aids, and W. W. Hubbard of the Experimental Farm, and looking forward to a similar profitable and delightful outing next year.

The Evening Times commenting on the Orchard Field Day says:

"Members of the party who observed "field orchard day" yesterday by inspecting the orchards along the banks of the St. John river were deeply impressed by the possibilities which the province offers for fruit growing. If these gentlemen, who already were interested in this phase of the development of the country, were surprised by what they saw, what would have been the effect upon other residents of New Brunswick who have paid less attention to the subject? We are entirely too modest about our provincial resources, and whether this modesty has its origin in lack of information or lack of appreciation it is not a trait which makes for rapid progress in the development of the province.

Experts have pronounced apples grown in New Brunswick on a par with the best and superior in some respects to the product of more famous apple regions. The introduction of more modern methods of growing and cultivation and improvements in packing and shipping have enabled New Brunswick apples to secure a foothold and a growing reputation in outside markets, but only a beginning has been made. Wide stretches of land, particularly along the river banks, offer exceptional opportunities for the production of apples on a scale which would provide a generous income to many people and add much to the wealth of the province. Many, already residents of the province, might turn their attention in this direction with profit to themselves, and the opportunities offered should provide a strong attraction for a desirable class of settlers from other parts of the world.

The opening of the Valley Railway will furnish access to a country well suited for orchard development and should result in increased attention being paid to this source of wealth.

United Farmers Adopted a Definite Party Platform

Platform of the United Farmers of N. B.

No. 1. Whereas a call to the United Farmers of the different local branches for the putting up independent candidates to represent the different constituencies both in the Federal and Local houses and that the responses have been practically unanimous in its favor, therefore we, the officers and directors of the United Farmers, authorize the organizing director of each county to call a convention for the purpose of selecting candidates for both Federal and Local houses.

No. 2. Since it is absolutely necessary to have campaign funds for legitimate purposes, we would therefore authorize each county to raise and control such funds with the provision that it shall be itemized and audited and forwarded to the Secretary of the Central Association and the source from which it is derived.

No. 3. That we are entirely opposed to any form of bribery and corruption in elections.

No. 4. That wilderness and unimproved land be taxed in proportion to the tax on improved land at the same rate and on the same basis.

No. 5. That the registering of Mortgages be changed so that the amount actually due on mortgages can be ascertained at the registry office every year, such mortgage to be exempted on amount of mortgage still unpaid, and the holder of the mortgage be assessed on the amount and the taxes paid in the district wherein the land lies.

No. 6. That we propose an act to be passed by our local legislature compelling any trunk telephone to give proper connections with Local or Farmers' line for a reasonable toll.

No. 7. That before any increase in telephone rates should be made, a full investigation be made before the proper authorities open to all parties interested, showing such increase to be justifiable.

No. 8. That any man 18 years old be allowed to homestead 100 acres of land and a returned soldier 200 acres with the privilege of buying 100 acres additional in the Province of New Brunswick.

No. 9. That we will work for an Abattoir, an establishment of a cold storage plant and stock yard in the Maritime Provinces.

No. 10. That the Provincial and Federal representatives pledge themselves to resign on being presented with a petition signed by 60 p. c. of the members of the U. F. of N. B. asking them to do so.

No. 11. That we are in favor of total prohibition of the manufacture and the sale of liquor as a beverage and that plebiscite be taken at any time.

No. 12. That we are in favor of general improvement of the roads of N. B. rather than the building of a speedway for autos in the province, and that we use auto taxes for Highway purposes only.

No. 13. That we have a uniform system of breaking winter roads and they, the workers, receive pay for doing it.

No. 14. We should aim to have the government of the day to appoint a Farmer as Minister of Agriculture.

No. 15. That the Secretary of Agriculture be a Farmer, a Farmer's Son, a native of N. B. and a graduate of the college of Agriculture.

No. 16. Whereas the United Farmers represent the Farmers more than any other organization, we would ask that the United Farmers be consulted on the general policy of the Agriculture.

No. 17. That we recommend a rural delivery daily mail service be established in every country district.

No. 18. That we adopt the Platform of the Canadian Council of Agriculture with the addition of clause G. to section 4, which reads as follows:

That firms holding charters for the development of the natural resources of the province. That these charters be cancelled unless the work be carried out within a reasonable time.

And the Exception of Section 9, which reads as follows:

Public ownership and control of railway, water and aerial transportation, telephone, telegraph and express systems, all projects in the development of national power and of the coal mining industry.

N. B. LIVE STOCK SUPT. GOES TO TORONTO STOCK YARDS

Thos G. Hetherington, B.S.A., Live Stock SuperinStendent for the New Brunswick Department of Agriculture, has tendered his resignation to the minister of agriculture, to take effect this month and has accepted a position in the Toronto Stock Yards under the Dominion Live Stock Branch.

Mr. Hetherington is a conscientious hard worker. During his term of office in New Brunswick he has done a great deal of good work in upbuilding the live stock industry of the province. He has been the means of starting many young farmers along the right line in stock breeding.

The Maritime Farmer voices the sentiments of all those with whom he worked when we wish him every success in his future undertaking.

THE PASSING OF J. A. FLOYD

In the passing of Mr. J. A. Floyd, of Bloomfield Station, Kings County, after a short illness at the St. John Hospital, the province of New Brunswick lost one of its most intelligent and progressive farmers. The late Mr. Floyd took an active interest in anything and everything that tended towards the betterment of his community and calling. He was a prominent berry grower and shipper and was well and favorably known. He is survived by his wife, two odaughters and two sons. One of the sons is the popular and energetic L. T. Floyd, Provincial Apiarist for New Brunswick, while one of the daughters is Mrs. John Woods, whose husband is so well and favorably known as a valued member of the staff of the New Brunswick Department of Agriculture in charge of darinage propaganda.

The Maritime Farmer extends the sympathy of its readers to the bereaved ones.

THE MARITIME FARMER

And Co-operative Dairyman
Registered Trade Mark

Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definite order for discontinuance is given,

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsible advertisers. To take advantage of this guarantee, written complaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said:—"I saw" your adv. in the MARITIME FARMER.

GAMBLING IN LIVE STOCK

Changing over from one line of live stock to another, seems to have been a popular practice with a large number of farmers of late. Of course it goes without saying that the farmer who makes such a move has reasons for doing so which may appear quite convincing on paper, regardless of how they work out in practice. But to boil the matter down into a nutshell there appears to be two general causes behind such action. In the first place there is the question of labor supply. Shortage of help has forced many a man out of the line of stock he has been specializing in, regardless of his own inclinations in the matter. In a case of this kind the man on the ground is the only on who knows just what sort of a proposition he is up against, and he alone can prescribe a reliable remedy. But, nevertheless, there are plenty of cases where farmers have changed from one line to another, purely in an attempt to cater to the highest market, and it is the wisdom of this kind of policy that is open to question. Perhaps the element of risk involved can best be explained by taking a purely imaginary example. Let us suppose, to begin with, that beef prices are very high; here is a farmer who has been handling dairy cattle for years and doing fairly well. But he gets figuring on the beef proposition, and convinces himself that there is more money in beef cattle than dairying. Accordingly he sells his dairy cattle on an average market and buys stockers on a high one—a transaction of questionable wisdom in any sphere of business. It requires a litle time for him to get his new business on a good working basis, and the chances are that by the time he gets into his stride, beef prices will have suffered a reaction and will be once more back at normal. This, coupled with the fact of his discovery that he has quite a lot to learn about beef cattle raising is more than likely to make him sick of his bargain and anxious to get back into his old line that he knew so thoroughly. But to do this he must sell his steers in a normal market, and if it so happens that prices of his own line of stock have meanwhile advanced—well, the experience will be complete and convincing even though rather costly.

Of course, events do not always develop into a wreck, like the case cited, but recognizing the general rule that ups and downs follow one another alternately, the man who buys on a high market stands a pretty fair chance of selling on a low one at a loss. Hence in nine cases out of ten the farmer who comes out best in the long run is the one who stays by the line of stock that he knows so well, through thick and thin, rather than plunge here and there gambling on the turn of the market.

SOME DEATH TRAPS AROUND FARM HOME

There is no denying the fact but that the country is the safest place in which to live, and yet, many accidents happen annually in rural districts from carlessness or neglect. Only a few days ago whie driving along a country road in passing by a farm house we noticed a large limb that had broken off a huge maple tree which was standing in the lawn. That limb in falling had dropped quite close to the front door of the house where the children often played. In fact as we passed by three little tots were playing around that very tree. What would have happened if they had been there when the limb came down? There is no use going any farther, but it looked like carlessness to leave that limb there until fell of its own accord. Possibly its weakness could not have been seen beforehand, but that does not often happen.

There are a great many such cases occurring every year. Some may happen without any previous warning, but the large majority of them are looked for and always come before they are expected. Why any farmer should neglect such a simple operation as sawing off a broken or weak limb before it tumbles down in his door yard seems hard to understand. Children may be warned about playing around such places which are known to be dangerous, but when a number of them get together they forget all about the danger and sooner or later may get hurt.

The policy, therefore, of every farmer who has trees growing in his yard should be to have a thorough examination of weak limbs conducted annually or oftener if found necesary. It may mean a litle effort but result in saving someone's life.

VALUABLE PAPERS OFTEN DESTROYED

Every farmer should provide himself with some kind of a fireproof box in which to put his valuable papers. No matter how small the farm may be there are always valuable papers around that require more protection than that afforded by the top drawer of the bureau. There are always deeds to property, insurance policies, wills, notes, both given and received, live stock pedigrees, etc., most of which can be replaced if lost through fire, etc., but that costs considerable in time, money and inconvenience.

What usually happens when the average farmer is asked for some valuable paper such as a pedigree, deed, etc? He calls his wife and together they search every drawer and box for it. Sometimes they find it, but only after a search of half an hour or more. That should not be the case. If papers are valuable enough to pay good money for recording them they should be worth looking after. Suppose a fire should break out in the farm home, every available hand would be kept busy either putting out the fire or removing the furnishings before the rapidly devouring flames and if these valuable papers were scattered here and there as they are in too many farm homes, they would likely be lost. This can be prevented to a large extent by the purchase of a fireproof box which every farmer should have. Such a box can be purchased for seven or eight dollars, and although not absolutely fireproof in a continuous fire, it is a big protection and seldom fails to preserve the contents. Not only does it serve as a protection in case of fire but it gives quick access to the papers at all times. They are always in the box and it is only a matter of a few minutes to find them when required. These boxes are provided with a lock and key which makes them all the more safe, and should be used by every farmer or business man who has not easy access to a fireproof safe. The few dollars spent in buying such a box would not go far in having duplicate certificates made if by any reason they should be destroyed.

THE FARMER'S LIFE

Now let the men who find fault with the farmer and the way he conducts his business, take one year's vacation from the very hard and tiresome jobs they are holding down and go to the country. We will not ask them to work, all they need to do is: Get up at five o'clock in the morning, see the sun rise for 365 days, as the farmer does, go with him to feed the stock, milk the cows, watch him take a little manual exercise—hopping clods; come in at eleven-thirty, feed the horses, slop the pigs, go to dinner at twelve, then sit out in the shade for one long hour; back to the field at one where you go through the same exercise you did before noon, and keep it up till the sun goes down. Did you ever see a more glorious sunset?

THE PART NATURE PLAYS

In breeding cattle and plants, Nature throws us off the track of certainly by her universal law of variation. We find in dealing with the soil that nowhere can we be "cock sure" that we are right. But we do find that those men are nearest right, the most successful, the closest guessers, who bring to their task the most enlightened and comprehensive minds. To such minds Nature yields the largest number of her secrets and with that they must be content. Nature has no mercy for the self-willed, the narrow-minded, and the ignorantly conceited. They have no reverence for her and so she treats them with contempt, making their punishment oftentimes "harder than they can bear."

Every dairy farmer should see that he has the necessary equipment to make the labor of himself and helpers count for as much as possible. Whenever improved barn fixtures, litter carriers, feed trucks and carriers and milking machines can be used efficiently, they should be put in. The milking machine especially is a great labor saver, as with it one can take care of about three times as many cows as he can without, and in this way it adds greatly to the efficiency of his labor and to his output of food products.

* * *

When a man buys a purebred, part of the purchase price unquestionably represents the certificate of registration. He buys the individual first, but at a price considerably above the market quotations. That extra price represents what he pays for confidence in and knowledge of the animal's ancestry. The certificate of that confidence and knowledge is the pedigree. He pays extra for it. If it is not forthcoming promptly he is cheated. Another way of saying it is "Pocketing the cash and neglecting the papers."

BARN VENTILATION

(Continued from page 833)

though they may be made as small as 12 inches square in a low barn with a low or no loft.

In barns of the narrow type, the out-take flues can generally be made in two sections with the boards running the full length of each section. In such cases, and where the flues are small enough so that the sides may be made with two widths of shiplap, the flues are often built up with the 1x2 inch cross pieces on the outside instead of between the two layers of boards. One needs to be careful in the selection of the proper width of boards. The two flues shown below are sizes commmonly used in the narrow barns, and are therefore worthy of special study. The smaller flue is made up as follows:—

Inside layer: 6 lengths of 1x8 inch shiplap, 2 lengths of 1x10 inch shiplap. Outside layer: 2 lengths of 1x8 inch shiplap, 6 lengths of 1x10 inch shiplap.

Material per length of the larger flue below:

Inside layer: 2 lengths of 1x8 inch shiplap, 6 lengths of 1x10 inch shiplap. Outside layer: 6 lengths of 1x10 inch shiplap, 2 lengths of 1x12 inch shiplap.

When figuring sizes, it should be remembered that shiplap is always under size. For example, 1x8 inch shiplap is ¾ of an inch thick and very nearly 7½ inches wide over all. If one edge is taken off, the width over all is redueed to 7 inches.

While building up the inside layer of the flue, the boards are held together by temporary cleats tacked on the inside surface, using 2 inch nails. These inch stripes are knocked off when the section is completed and after th eoutside cross pieces have been securely nailed in place. When putting on the temporary strips, do not drive the 2 inch nails in up to the head.

Construction of Wells, Etc

If any system of ventilation is to work well, the loft floor must be tight, and the underside of the floor joist ceiled, unless there is a thick layer of chaff on the loft floor. The inside of the studding of the stable should be covered with V joint, or tongue-and-grooved stuff or shiplap. For Manitoba conditions, the wall outside the studding up to the loft floor should consist of one layer of shiplap covered with at least one thickness of building paper, and finished off with barn siding.

The Two Systems of Barn Ventilation

There are only two systems of barn ventilation that have thus far proved their worth, and even these are not successful in our cold weather conditions, unless properly installed and carefully operated. One is known as the Rutherford and the other as the King system. This bulletin is calculated to give the reader, in as brief a manner as possible, an elementary knowledge of the systems already in use, with some suggestions and comparisons. It may be well to state at this point that many minor details in ventilation construction applicable to warmer states and provinces will not always be found satisfactory under colder conditions.

The Rutherford System

Size and Number of Intakes

In the Ruetherford system of ventilation the fresh air enters the intake flues just above the ground level, turns downward, passes inside the stable and then rises. The outside is commonly protected by a little slanting roof and louvres which may be hinged at the top for cleaning out. If the system is installed when the barn is built, the in-take flues may be built in the foundation wall, or if the system is installed later the flues are put in above the floor level, or even above the sill. The Rutherford intake is especially applicable where the animals face out, as the manger protects the stock from drafts, while the fresh air comes right in at the heads of the animals. On the inside a partition of concrete or wood rises above the floor level to keep the dirt from sliding into the flue, and to direct the entering air upwards. Covers should be provided for closing the intakes in windy and extremely cold weather. It is well, also, to protec them with coarse screens to prevent their becoming filled with leaves, straw, etc. The small mesh poultry screen does very well for this purpose . From 8 to 10 square inches of inlet area per head of cattle is commonly recommended by the advocates of the Rutherford system. Horses should be given 10 to 12 square inches of inlet area. If a barn contains 30 head of stock, the total area of the intake flues should not be more than 300 square inches. If four in-take flues were put in, the area of each would be 75 square inches, or an opening 5x15 inches, which would make a bad draft. If six intake flues were used, the area of each would be 50 square inches, or less, which would give an opening of about 4x12. For Western condition, where there is a great deal of wind, a large number of smallerr intakes would be preferable to a smal number of large intakes. In the above case, eight in-take flues would be better.

Number and Location of Out take Flues

In the Rutherford system the out-take flues start at the ceiling, and pass up through the loft (usually alongside the purlin posts, if there are any) to the cupola, being put in pairs in large barns. There will probably be one or two in the small barn, four in the ordinary barn, and six in the very large barn. 8he out-take flues can be carried up through the roof in various ways. In one the flue leaves the purlin post and takes a steeper slant up to the cupola, which is better than following the slant of the roof, in so far as the ventilation system is concerned, but takes more space in the loft. By following the purline post and then out through the roof affords the most direct exit for the foul air, and is, in the writer's opinion, the best one to use. It is a litle unsightly, and the out-going air cools a little more rapidly in the proportion above the roof exposed to the direct contact of the cold winter winds, but the suction is greater, and the hay track can be put in higher by not having the outlets feed into the cupolas. Also the cost of construction should be, if anything, a little less in the case of the straight out-take flue. When installing out-take flues, avoid carrying the flues along horizontally when it is necessary to get to the cupola, but rather keep the flues slanting upwards, by running them diagonally along under the rafters to the cupola.

Size and Regulation of Out-takes

The total area of the outlet flues in the Rutherford system is made twice the total area of the in-take flues. In other words, sixteen or more square inches of out-take flue area is allowed for each cow, and a little more per horse. Thus it is figured (and correctly so) that a good deal of the fresh air entering the stable comes in around the doors, wndows, etc. The outlet flues are controlled by means of dampers, where one can readily see if they are open or shut. The dampers should be pivoted slightly off centre and regulated by a cord. These dampers should fit well. It has been found best to entirely close some of the out-takes in very cold weather, rather than to partially close all. In the latter case the flues would not handle enough air to keep them warm, and they would condense the moisture in the outgoing air, and fill with frost, and would then drip badly with the next rise in temperature.

The King System

Intake Flues

In the King system of ventilation, the fresh air enters the in-take flue just above the snow line and rises between the studding, which forms two sides of the flue, entering the stable a little below the ceiling, where the cold incoming air mixes with the warmest air of the stable with the idea of avoiding drafts as much as posssible. The in-take openings should be ten or twelve inches below the ceiling. Professor King recommended a large number of intakes rather than a small number of larger ones. For cold climatic conditions it would be well to have at least three times as many in-take as there are out-take flues. The outside opening is screened with coarse mesh wire. The inside opening is regulated in various ways by means of cast iron registers, sliding dampers, or by a door, hinged at the bottom and controlled as to position by means of a stick, beinig dropped into notches on the side of the wall below the opening.

Arrangement of Out-take Flues

Theout-takes in this system are put up in pairs. They take the air at a point about a foot above the floor and pass up and along the inside of the stable wall to the loft, one flue entering the cupola from each side of the barn. In the stable proper, the flues are made about twice as wide as they are deep in order not to project too far out from the wall; ;but at the loft floor, they should be made square to reduce the outside cooling surface to a minimum. They pass up through the loft in various ways: they may pass up along a roof-bent; or they may pass out of the roof at the curb; or they may pass up along the under side of the rafters, the latter being the least preferable. When the rows of stalls run across the barn, the out-take flues are often put in beside the posts supporting the loft floor and pass up through the loft beside the purlin posts. 8he number of out-takes used is about the same as already referred to in the Rutherford System.

Control of the Outtake Flues

While in cold weather the air is made to enter the outlet flue at the floor, an opening is also provided at the ceiling in order that the warmer air of the stable can be removed, when the temperature in the stable rises too high. This opening can be controlled by a slide or a door hinged at the bottom, similar to the method shown for controlling the in-take opening.

Size of Flues

In the King System the total area of the out-take flues and of the in-take flues are generally made equal. While this is satisfactory where the winters are milder and less windy than in the prairie provinces, for our conditions it would be better to have the total area of the intake openings about two-thirds that of the out-take flues, for leakage around the windows and doors will easily provide one-third of the ventilation. From the following table it will be readily seen that the recommended amount of flue area per animal is much greater than that recommended under the Rutherford system, which means that for flues of the same height and under similar weather conditions the King System will give at least fifty per cent more ventilation than does the Rutherford System, all other conditions being equal.

Area of Out-take Flues per Animal

Height of flue	40 ft.	30 ft.	20 ft.
	Square Inches		
Horse	36	40	44
Cows	30	34	38
Pigs	12	14	16
Sheep	8	9	10

Areas per Animal for King Out-take Flues

Height of flue	40 ft.	30 ft.	20 ft.
	Square Inches		
Horse	24	26	28
Cow	20	22	24
Pig	8	9	10
Sheep	5½	6	6½

These figures provide ample area for still weather conditions and where the temperature is 15 or 20 degrees F. above zero, under which conditions we have a slower movement of air than when it is colder and more windy. Therefore the flue area must be greatly reduced in windy and very cold weather.

Frosting of In-take Openings

A slight objection to the King System of intakes for our climatic conditions is, that the air rising through the flues makes the inside walls very cold, and in the coldest weather the moisture in the stable forms a thick layer of frost on the wall at these points. The frost, if not scraped off, melts and runs down the wall at the next rise in temperature. This trouble will occur, to some extent, around any in-take openings in the coldest weather. In the case of the King inlets it can be largely overcome by making a dead air space between the intake studding.

FURTHER SUGGESTIONS

Flue Regulations

With any system of ventilation, all the intake openings should be partially closed in cold weather rather than to shut off some entirely except when the wind is blowing strongly against one side of the barn, in which case the intakes should be almost closed or entirely closed. A test of intake flues in windy weather will show nearly all, if not all, of the fresh air coming in on the windward side of the barn and none coming in on the opposite. But if the intake flue openings on the winward side are cut down, fresh air will be drawn in on the opposite side also, thus giving a more uniform ventilation throughout the stable, and overcoming the tendency to drafts on the windward side of the barn. In very cold weather all intakes are closed and half the out-takes entirely shut off; and even all outlets should be closed but one, when the temperature is extremely low.

Methods of Protecting Inlet Flues from Heavy Winds

One of the main points to be watched in the operation of a ventilation system is the regulation of the intakes. If the intake flues are set for still weather conditions and a strong wind sets in before morning, the animals in the windward side of the barn get too much cold air. This is probably more true of the King inlet than the type of Rutheford inlet discussed, though the King inlet gives the incoming air a better chance to spread before reaching the animals. Here is an arrangement tested out by the writer for protectinig the outside openjng of the King inlet flue from the direct force of the wind. There are no louvres on the front, but openings at each end directly under the little slanting roof. The roof should overhang the opening about three inches. With this arrangement, if the wind is blowing squarely against the side of the barn, the ingoing air has to make two right angle turns before it can enter the intake flue proper, which would considerably cut down the evlocity of the entering air. If the size of the two openings be made about two-thirds of the area of the intake proper, this will help to reduce the velocity of the air entering the stable. From the tests made, it was found that this form of protection was of material advantage when the wind was blowing squarely against the side of the barn; but when the inlet opening is so located that the wind strikes it at an angle, the protection is of little value.

HORTICULTURE.

A FEW NOTES ON ANT HISTORY AND HABITS

(By Rev. H. J. Fraser)

There is a very wonderful world lying about our doors, a world full of little beings with their loves and hates, their ecstasies and tragedies, their wonderful skill in work, and their approaches, to say the least, to human intelligence and imagination. Among these, the subject of this little paper, the ant, ranks very high, so high, that for my part I must confess that she commands my most sincere and rapturous admiration, although she is not always my friend. In some respects I admit at once she is my superior, and it does me good to know that great and might as I am, there are others, and some of them are most humiliatingly small.

The ant family outnumbers by far all other terrestial animals, exists in a great range of variety, and inhabits all sorts of geographical regions, from Arctic to Tropic, from dampest forest to driest desert, and from the top timberline of the highest mountains to the sand dune on the lip of the ocean. Their colonies, when favorably located, are remarkably stable, often outlasting a human generation, while the individual has been known to attain the age of fourteen years, a veritable Methuselah in the insect world.

Some striking, if apparently fanciful analogies to the human race, have long been noted. As human civilzation is marked off in stages, the hunting, pastoral, and agricultural, preceding in order of time the present industrial and commercial period, so among the ants the first three of these are observed, not, of course, in any time sequence, but marking different varieties.

In the hunting familes the communities are small; they fight singly and each individual finds its own food. The pastoral varieties live in better houses, act in concert, fight in armies, conduct organized food forays, and enslave the young of conquered foes. A most interesting habit of the pastoral ant is its adoption of the honey secreting aphis. A colony of ants often house and attend these little creatures in return for the honey they collect, using them precisely as the human family uses the cow. When we examine the habits of the agricultural types, there is a variety of opinions as to their planting and growing grain for food. Some observers claim that they actually and intentionally plant the seed of their favorite ant rice. But the consensus of opinion among careful writers is that the ring of these plants so often seen about the colony is due to the fact that seeds are often dropped or pushed out among rubbish and become sufficiently covered over to take root and grow. It is well known that germinated seeds found among the winter stores are immediately expelled.

Perhaps the most interesting habits to be noted in the agricutural stages are those of the fungus growing ants. These collect organic matter of such quality and preserve its moisture at such a degree as to grow a fungus which constitutes their favorite food. This is stored in chambers constructed specially for its reception, and when a female goes off to start a new colony, she takes with her as a sort of marriage dowry, a piece of fungus to form the nucleus of the food supply for a new generation.

If in all this there are striking analogies to human beings and their ways, the ant world has as striking differences. Possibly they have only preceded ourselves in that particular, and we are soon to follow in their footsteps. At any rate the male among ants has a very limited sphere, and as a member of the community is quite negligible. Then, the ant is born to a calling. There is never a change by superior training or prowess from one grade to another. Karma ordains her station and there she remains. In government the ant colony is an anarchistic socialism, but as far as can be imagine dfrom the insane and inane Bolshevikism. It has no ruler or general in ordinary times because it needs none. Each individual knows her work and does it, and there is seldom any evidence of confusion or conflicting counsel. In war there seems to be a supreme command, or else so perfect and universal a knowledge of strategy that action is concerted and purpose unified and definite.

There is one particular in which the ant so far excels us that we can never hope to emulate her. The writer remembers reading Bill Nye's History of England, wherein is described the fate that befell Charles I. After commenting on the quarrel with his Parliament the author states that it had the King amputated at the first joint: laconically adding: "He died soon afterwards." An ant has been known to live 41 days after its head had been severed from its body, during 40 of which it walked about with apparently little sense of loss.

I should like to add two or three authentic stories which indicate either the ability to reason upon a given situation, or the ablity to seize upon accidental circumstances and turn them to the best possible account.

The first I shall relate to do with a species of ant which makes its nest of large leaves, bending them into a kind of tent. A colony of these was observed fastening down the edge of a particularly large and stubborn leaf. At some points the edge was too far away for a single body to span the gap, whereupon one worker seized another about the waist with its jaws, this one a third, and so, by a living cable drew down the leaf. Next came the duty of fastening it in place. A number of workers bore pupae, which secrete a viscid fluid, in their jaws, rubbing these along the edges to be fastened together. They were clamped into position by the jaws of a number of workers and there held until the glue had sufficently toughened to hold them secure.

An experimenter suspended a sugar bowl by a string from the middle of a window top in a buiding infested with ants. At first, after discovery, they travelled up and down the string carrying off particles of the coveted delicacy. After a time, however, a number of ants were observed at work in the sugar bowl carrying the little crystals to the eedge and dropping them over, whereupon these were seized by their comrades below and carried off.

The last I shall mention, illustrates a curious limitation of this wonderful litle creature. A colony home had become untenable, and workers had gone forth in different directions to locate a suitable spot for a new city. One worker at length found a satisfactory place, and, returning by the roundabout route she had come, seized another in her jaws and bore it to the spot. The two then returned and seized two more and so the process continued unti lthe whole colony had been transplanted.

At times while refreshing my information for this litle sketch, the hour has grown late, and my head has begun to droop in spasmodic nods. Then suddenly, into my fast-benumbing consciousness has come a mighty voice form a far away land and time: "Go to the ant, thou sluggard! Consider her ways and be wise, which having no guide, overseer or ruler, provideth her meat in the summer and gathereth her food in the harvest," and I have realized that somebody in Solomon's day, possibly the great and wise king himself, had lain beside an ant hill and watched and wondered, an that the ant he saw then, three thousand years ago, was just the same busy, provident little creature that we have tried to watch ourselves, in our so different day.

BEEKEEPING ON FARM PROFITABLE

It is undoubtedly a fact that the desire for and the use of sweets is as universal in every family as that of the bread, the meat and various other foods that find a conspicuous place on the tables of the multitudes who find homes in this country. In fact, the make-up of the physical man demands sweets, or sugar as it is usually denominated.

As all well know, the sweets now demanded and required, are derived from several sources. Most all are included when sugar and syrup from the tropical cane, sugar beets, the product of sorghum, maple groves and honey stored by bees are named. Of all these, that delightful, healthful and universally liked product of the

HANTSPORT, N. S.

honey bee, is the one now to be briefly considered.

In a sense, the world where climatic conditions are at all favorable, is a vast flower garden. And in all this variety and abundance of blossoms ranging from the tiny snowdrop that gladdens the chill spring of the far north, to the gorgeous magnolia of the tropics, nectar is extracted and stored by honey bees in just such quantities as bees are available to gather it.

This brings us to the point of saying that the honey resources of this country are scarcely touched after a strenuous season of industry by the bees has been completed and they have retired to their winter quarters for a brief season of rest. Great as the honey resources are in the general and natural way, I want to call to the attention of present and prospective beekeepers, how they easily can provide on their farms and near the apiary, whole fields of continuously and abundantly blooming crops for their bees to store honey from, that but a very few beekeepers give any particular attention.

The special crops that farmers can and should grow on large areas of their land, if they desire large and continuous flows of nectar for a large number of stands of bees, are alsike clover, buckwheat and white clover. Besides these special sown crops, their bees get all the advantages of the honey flow from that which is common, namely, that of fruit and forest trees, and wild and cultivated flowers, giving forth an abundance of blossoms at stated seasons.

Now, in conclusion, if all the available nectar from the multitude of blooming trees, shrubs, and all other sources, could be stored by bees as a honey product, the quantity would far exceed all the sugar and syrup now derived from cane and sugar beets.

Cut Your Cost of Potato Digging With an O.K. Potato Digger

The O.K. Canadian Potato Digger will dig your potatoes quickly and at half the cost. It is being used by experienced potato growers all over Canada, and has proven itself again and again to be a reliable and efficient digger.

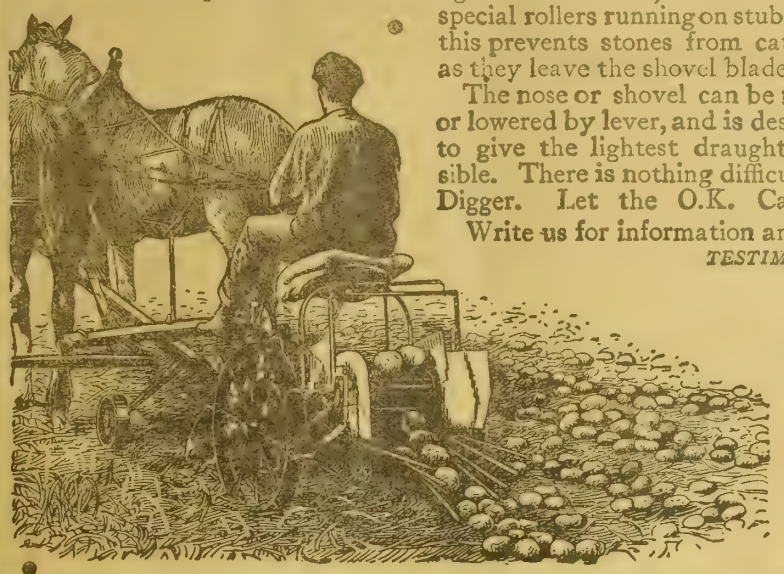
The throat is wider than on any other machine, and allows the earth to spread itself freely when entering. The sides are curved so that the vines and weeds do not catch but slide up to top of carriers along with the potatoes.

The apron has alternate high and low links, and moves over special rollers running on stub axles: this prevents stones from catching as they leave the shovel blade.

The nose or shovel can be raised or lowered by lever, and is designed to give the lightest draught possible. There is nothing difficult about operating an O.K. Digger. Let the O.K. Canadian do your digging.

Write us for information and testimonials.

O-K Canadian Potato Digger



TESTIMONIAL

Quyon, Que. Dec. 6th, 1918.

Dear Sirs,—

I bought a Digger No. 1 five years ago, and must say I have been more than satisfied with it. It is an O.K. machine. I have tried it with other machines and find none better for all quality of ground. Yours very truly,

H. F. Craig.

HOW TO PREVENT BEES SWARMING

The time when success in bee-keeping was measured by the number of hives or swarms hived has passed, and nowadays the progressive bee-keeper endeavors to prevent swarming as much as possible. The reason for the change is that bees are more easily handled, there are no lost swarms, and generally speaking one large hive properly handled produces more honey than if swarming is allowed, and the bees distributed in several small hives. In fact, instances are not rare in which unrestricted swarming has entirely prevented the production of surplus honey in a hive. But on the other hand it is not too much to say that the successful control of swarming is one of the most difficult problems the bee-keepers of Canada have to deal with, and a most careful study of the bees' behaviour is needed to cope with it. Fortunately for the bee-keeper, several days' notice or warning of the probability of the issuing of a swarm is given by the appearance of eggs in the queen cells.

Colonies very much in their propensity to swarm, even under the same conditions, but by replacing the queens of colonies that swarm, with queens that are the progeny of queens whose colonies have not swarmed, the bee-keeper may hope to reduce the percentage of colonies that swarm. Another point worthy of note is that colonies containing queens under a year old are less inclined to swarm than those in which the queen is older. However, at the present time the most successful methods of swarm control are two: First, by giving abundance of ventilation and room at the mouth of the hive in warm weather, and secondly by preventing overcrowding and giving ample room to store the honey by adding a super, preferably one containing empty extracting combs directly above the brood chamber as soon as the brood chamber is almost full of bees and honey is coming in. As soon as this super is filled with honey another one should be placed between it and the brood chamber. A good way to provide ventilation at the mouth of the hive is to place a thin wedge under the edge of the bottom box, thereby raising the box from the floor of the hive.

If these manipulations do not prevent swarming it may be necessary to add to them the more effective one of enlarging the brood nest so that it will become less crowded with young bees, and the queen will have more room to lay. A frequently successful practice is to put no queen-excluder between the brood chamber and the first super, thus allowing the hive to expand into the first super, but when the honey flow has started the queen should again be confined to the brood chamber by means of the queen excluder. Seven or eight days later any queen cell that may have been built in the super should be cut out. However, in many places it is often impossible to be sure of preventing swarming by this manipulation, and it is necessary from the time that the brood chamber becomes full of bees until all ikelihood of swarming has ceased, to open the hive every seven days and examine the brood combs to see if queen cells containing eggs or larvae are present. If any are found the combs should be carefully gone over and all of them should be cut out. At the same time, whether queen cells containing eggs or larvae are found or not one or two combs containing honey should be lifted out of the brood chamber and placed above the queen excluder. This practice will usually prevent or stop preparations for swarming.

PREPARING BEES FOR WINTER

(Experimental Farms Note)

The preparation of bees for winter should begin in July.

Every colony should have a young laying queen before the end of this month. Year old queens should only be retained if they are in full vigor. This means the raising of a large number of bees in August and September, and thus the first essential of good wintering—abundance of young bees in each hive—is fulfilled. A colony containing a young queen will also breed more bees and produce more honey in the following season than one containing an old queen.

If the bees are to be wintered out-of-doors, July is none too early to see about getting winter packing cases made, because the colonies should be placed in them in September. At the Central Experimental Farm, Ottawa, a case to hold four colonies in a block with space for three inches of planer shavings at the sides and beneath and eight inches on top, with outside entrances three-eighths of an inch wide by one inch high, has produced very good results in a place surrounded with a high board fence to protect the bees from the wind.

The third and last important factor in preparing bees for winter is an abundance of wholesome stores put away before cold weather. Clover honey, buckwheat honey and syrup made from renefid sugar have been found wholesome for wintering, but dandelion honey and some kinds of honey gathered in the fall have proved unwholesome. Colonies that have less than thirty or forty pounds of wholesome honey should have the deficiency made up with syrup consisting of of two parts of sugar to one of water. This feed should be given rapidly, not later than the middle or end of September, for the greater part of Canada. A 10-pound honey pail with a number of small holes punched in the lid makes a simple and efficient feeder for this purpose. It is placed upside dow nover the cimbs and covered with a super. Happily there are no restriction controlling the sale of sugar this year, but it would be advisable to secure a sufficient supply in good time.—F. W. L. Sladen, Apiarist, Dominion Experimental Farms.

IN BUYING DAIRY COWS BETER GET KIND THAT WILL LEAVE PROFIT IN BUSINESS

It is quite safe to say that the universal idea of goodness regarding a dairy cow is her ability to produce large amounts of milk and butter fat economically. The man who goes out to buy dairy individuals pays in a large measure according to ability to do. For this reason cow testing associations are operated and different cattle clubs carry on systems of official and semi-official tests, that we may nkow to a certainty as to their ability.

The long period test is practically the only reliable test, as has been proven time and again. In a case in my own vicinity in cow testing work, one cow started in making 70 pounds fat in a month, and was bragged about as the best cow in the association, but gradually dropped to about 10 pounds fat a month. Another cow making only about 50 pounds fat in her best month, kept close around this mark for the entire years, beating the former cow in yearly results by a large margin.

Education, or the early forming of habit, has much to do with persisting, and one should be especially careful the first milking year to feed liberally and treat them kindly, to milk carefully and thoroughly, and not discourage the milk giving functions. If a heifer hates the sight of you, hates to be milked, the chances are that all the feed in the world would not make a profitable cow out of her.

When we consider the cow as a manufacturing institution, taking the raw materials of the farm, and converting them into the finished product of milk and butter fat, then we should consider those points that make for a profitable, durable machine. These points are constitution, conformation, temperament, disposition and peristency, and beleive the order named is the order of their importance.

Although it really takes the five points mentioned to make a whole cow, if you leave out any one, you have an imperfect cow and an unprofitable cow. Some seem to enjoy having an unprofitable cow around, saying they have the feed and the boys to do the work and they san keep them as well as not. Very little progress, however will be made in herds where this condition exists.

The business of the dairy cow is to produce and reproduce, and the manner in which she accomplishes these things stamps he in the profitable or the unprofitable class. To produce large amounts of milk and butter fat requires an abundance of constitution, vitality and strength to carry her through, for often her work is done under adverse conditions.

She must also have some reserve constitutional force, for she must be able to resist or throw off disease germs which are so prevalent in many of the stables where sunlight and good ventilation are things unheard of. Constitutuion, in a large measure, depends upon the room in which the heart and lungs are placed. This part of the cow should be roomy, giving perfect freedom for these organs to perform their functions, as the milk is made by the blood and the blood is purified by the amount of oxygen the lungs may pump from the air. An abundance os nourishing easily digested food is also an important factor in building up and controlling vigor. If the human body gets weakened, physicians prescribea diet of easily digested, easily assimilated food so it is the business of the feeder to watch his indivduals and keep them in a healthful condition.

The conformation also means much toward the production of milk, in fact her whole make-up contributes something to the perfect dairy type. A celebrated breeder once said if he could see an animal's head he would not need to see more, as the head would determine the rest of the body. This is true in a measure although I would rather see the whole animal. The medium sized, angular head would indicate an angular, medium sized body, and the short, compact head a correspondingly compact body, with a tendency toward beefiness, while a longer angular head would denote a large open jointed body with little surplus flesh.

A broad mouth is always indicative of good feeding qualities and as this is the business of the cow, this characteristic should be sought for and bred for, which together with a bright open eye and distance between the eyes and a strong muscular jaw would constitute an almost ideal head for a good dairy cow, and should be connected to the body wth a long, thin neck, free from meatiness.

The idea of extreme angularity of the body is not as prevalent as formerly, for sows of this make-up often lack conctitutional vigor, and when put to the test of large production, lack sufficient stamina to carry them through.

A large barrel to a cow is compared to a large storehouse for manufacturing institution, a place where material is stored for manufacturing purposes. A cow should have a good capacity of body, for it takes a lot of food to make a lot of milk. k

The udder should be capacious and well attached to the body, extending well back and well forward, occupying a large space on the body. It should be free from meatiness and covered with a soft, pliable skin. Udders of this character are more easy to empty out and are associated very closely with persistency. The teats should be of good size and well placed, which make the work of milking desirable and more pleasurable.

The milk veins should be prominent and elastic to the touch, with the milk wells large and numerous. These are an indication that the blood flow is going in the right direction, and are always in evidence on every good cow.

The temperament of the cow is an essential feature, and the term "nervous temperament" is often confused with nervousness and excitability. It is simply what we might term "dairy organization" or an ability or disposition to eat, digest and convert food into milk, except what is absolutely needed for the body maintenance. It also gives to her that stick-to-it-iveness which all dairymen like.

The good judge takes this in at a glance, he sees her bright, active eye, the expression of activity and intelligence in her face, the freedom of surplus flesh over the entire body, the open jointedness and the spacing between the ribs and the vertebrae, all of which are indications of a dairy temperament, and go to prove that she is a worker.

Disposition might be classed with temperament, but disposition is often caused by the bad disposition of her keeper. There are families that seem to be full of pure cussedness, and a cow of this charcater is always a source of annoyance to her owner and not make a good foundation animal. As this characteristic is usually transmitted, such a cow is usually lacking in genuine nervous temperament and has not sufficient nerve to be decent.

These points mentioned when blended together in harmony and symmetry, gives the cow an appearance of beauty which makes her attractive to her owner and consequently creates a deepe rinterest, which goes a long way toward making a good cow.—F.H. Scribner.

BRANCHES IN ALL CITIES

ies. With regard to butter the output of creameries declined from 1,090,501 pounds in 1914 to 500,050 pounds in 1917, so that last year's output indicate sonce more a rising scale. It is explained that the introduction of the hand separator encouraged home butter making and that since 1903 the factories have been much less active. Another difficulty was that of getting suitable labor for seven days in the week. With regard to cheese, the output in 1912 was 1,022,246 pounds, or with 152,000 pounds of what it was last year. The policy of the N. B. department of agriculture is to encourage co-operative butter and cheese factories, and the Year Book says: "It is noteowrthy that where farmers have taken hold of the dairy business with vigor and energy they have made it successful, as the character of the soil and the pasture lands of the province are eminently adapted to this branch of agriculture." It is pointed out that there will be an enormous demand from Europe for high grade dairy products for some years to come and that no farmers are more favorably situated to take advantage of it than those o fthe Maritime provinces. It is interesting to note that no less than sixteen of the cheese factories are located in one County (Kings) and they are found in only four other counties. Butter factories are fonud in eight counties, but there are only fifteen in all. Hence there is a very iarge field for the development of the industry. That progress is the watchword this year is evident from the formation of a New Brunswick Cheese and Butter Board, hich recently held its second meeting in the town of Sussex. Buyers from Halifax, St. John and Moncton, as well as representatives of packing companies were present. There were 1479 cheese boarded and the price received was 30 cents f.o.b. at the station nearest the factory. The average weight of the cheese sold was 70 pounds so that the sale represented $31,059 for the Kings County factories. The Board will hold regular meetings, and its establishment will no doubt stimulate the industry. The department is doing all in its power to encourage the manufacture not only of more but of better quality of cheese. A vigorous development of its dairying industry would undoubtedly be of great benefit to New Brunswick, and that appears to be the present outlook. —Maritime Merchant.

TWO KINDS OF A COW

There are two kinds of cows on our farms today,
Just two kinds of cows and no more, I say,
Not Jersey, or Guernsey, Ayrshire or Holstein,
For it isn't the breed of cows that I mean.

Not the fat, or the lean, or the large or the small,
Nor the ones that stand in the up-to-date stall.
No, the two kinds of cows on our farms that I mean
Are the cows that lift and the cows that lean.

The lifter is one that brings large returnes,
The leaner costs more for her keep than she earns.
Wherever you go you will find the breeds' masses
Are always divided in just these two classes.

And, strangely enough, you will find, as I've seen,
There are about 10 lifters to 30 that lean.
And the dairyman finds by testing and weighing
That these noble lifters do all of the paying.

—Frank E. Rounds.

Good butter is the result of handling at the various creameries nothing but milk and cream produced under sanitary conditions and manufactured in well equipped creameries and in charge of trained men. The making of butter, the kind that always satisfies the consumer is not an accident but the result of care and skill from the cow to the consumer.

Every owner of dairy cows should establish a definite standard, and all cows that do not measure up to the requirements should be disposed of for beef. Whether a dairy cow should be rejected or retained should depend ordinarily on production, as shown by the milk sales and the Babcock test.

THE LAST MILK THE RICHEST

The milk drawn last is always richer in butter fat than that milked first, and if the cow is not thoroughly milked she will lessen her milk flow. So to keep up the quality and quantity of the milk, milk the cows thoroughly.—Extension Division N.D. Agri. College.

"Tomorrow I will go into pure-breds."
And he gazed with dreamy eyes
Toward the misty clouds that were tinged with pink
From the glow of the western skies.
"And I'll show the big, indifferent world
How a good herd wins its way!"
But the prize he sought was won by the man
Who started his herd today.

Reputation

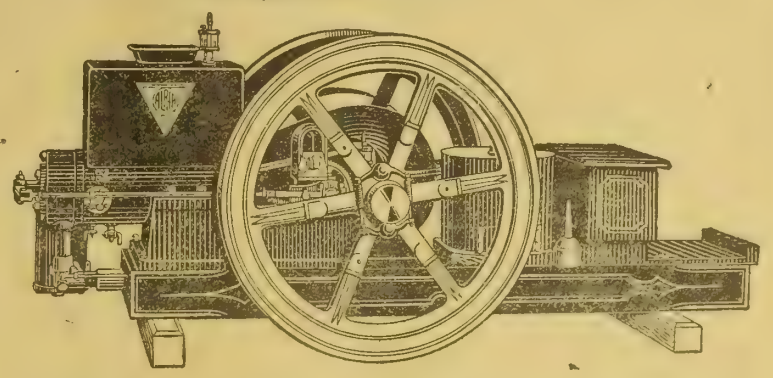
ALPHA Trade Mark

THE reputation of the De Laval Company is a most valuable asset. For over thirty years it has been building up this reputation among Canadian dairymen and farmers.

The ALPHA Gas Engine represents the same high quality among engines as the DE LAVAL Separator among cream separators. The reputation of the entire Company is back of every machine it puts out.

That is why the ALPHA Engine is a safe buy for the farmer. It is a dependable engine with thirty years of reputation for honesty and service behind it.

If you don't know who handles the ALPHA in your vicinity, write nearest sales headquarters for his name.



THE DE LAVAL COMPANY, Ltd.

"BREACHY" COWS ON THE FARM

"I had to sell one of my best young cows the other day," said a farmer, and proceeding to explain the reason this afrmer told how he had neglected his fences the last couple years, simply because his cows were not fence breakers and did not give him much trouble, and also the change that came in a few days. This one four-year-old cow developed the "breachy" habit and trouble came rapidly. She would break down the fences, the balance of the herd would follow ,and he had no end o trouble. His fences were not very good and the cows could go almost anwyhere they liked, consequently he was continualy fixing fences and often had to neglect his field work for half a day at a time. The result of the whole thing was that he had to sell this young cow that was always the leader, for a price which was far below her value, because she was a very promising young animal. Furthermore, he had already kept her too long, because she had started the rest of the herd and now they were always on the watch for a chance to break out of the pasture, a thing which was almost unknown before.

That is not a new story. It has occurred many times before, and it is safe to say that many readers of this paper have had similar experiences. Yet there is another side to such a situation. Why allow the fences to become so poor that a wholesale stampede results? In the case of the farmer referred to it was simply a case of over trust in the good behavior of his herd and it was carried just a little too far. True, he was more or less provoked ofr losing so much time repairing his fences and chasing the cows out of mischief, but yet he blamed no one but himself. He had neglected his fences and was reaping the results.

The above may be an extreme case, but many similar ones happen throughout Canada every year. The writer recalls that many years ago, when on his father's farm a herd of twenty cows broke out of their pasture and spent a night in a beautiful field of oats that was stacked up ready to be drawn into the barn. That particular crop happened to be one of the best ever grown upon the old home farm, it was the pride of its owner and the talk of the neighborhood, but that did not save it. In the morning only some twenty stooks in one corner of the ten acre field remained untouched; the remainder had been thrown helter skelter and badly damaged. The loss was a heavy one, not because of the oats that had been eaten but som cuh had been shelled, tramped and scatered about the field The other part of the story is not hard to tell. The fences were poor and a couple of "breachy" cows did the rest. The few hundred bushels of oats lost that night would have put new fences on a large part of that farm. It was an expensive lesson, but it had its effect, consequently the next spring a fencing drive began and the whole farm was gone over and made safe from the possibility of another loss as had occurred the year before. However, it did not end there, and an annual event afterwards was to spend a week or more if necessary fixing the fences, building new ones and gradually removing cross-fences so as to enlarge the fields. That had a twofold advantage; there were fewer fences to keep in repair, more material was available to fix the other fences, and the fields were larger. After all perhaps it could hardly be called a loss although it was hard to believe anything else at the time but it had the effect of leading to better fences and preventing a recurrence of the damage suffered.

The foregoing are not isolated cases, neither is the good that came out of them. It is simply a case of all prevention, not cure, and the only way to play safe is to keep the fences in the best possible shape at all times. If that is done it will only be a short time until many unnecessary fences will have been removed and the farm work made easier. The "breachy" cow is unknown upon the well-fenced farm and such a thing as having to sell a cow because she is continually leading the others and causing trouble is never thought of. It's simply proving the fact that good fences are a paying institution on any farm where live stock is kept, and that the fences should always be in reasonably good shape as there is no way of obtaining compensation after the damage has been done.

COWS GOING LAME

During the last few days a number of letters have been received from farmers complaining of cattle going lame. The description given of the affected animals has ben practically the same in all cases. The first symptoms seem to be soreness of the feet, a swelling above the hoof, in some cases the skin breaking and becoming raw and sore, and in all instances the animals go very lame. In some cases the swollen part, very red and inflamed, extends almost to the hock; the animals do not sem to be sick, and no deaths have been reported.

The cause of this trouble can be traced to the extreme wet weather. Animals put on pasture were frequently in wet low-lying places, and often in mud several inches deep. In other cases the pastures were reasonably dry, but the cows were forced through sometimes a foot of mud in the lane or barnyard and in the case of the latter the worst kind of filth, which in itself was enough to injure any animal. This filth was carried upon the heels of the animals practically day and night, and after a time it caused the skin to crack and the infection got into their feet. From that on things rapidly became worse and, of course, they got lame.

The cure for such cases is simply to remove the cause by putting the animals on dry pasture and avoid driving them through mud. This should not be a very difficult matter and when the main cause of the trouble has been removed the disease will rapidly diminish. If it does not, however, some effort should be made to [illegible] lar trouble will not occur again. Animals that are suffering with the disease should have the sores dressed with a solution of carbolic acid and water, 1 drachm of acid to 6 ozs. water, and the leg covered with a coal tar solution. Keeping the animals in a dry, clean field or stable and dressing the wounds as above will soon remove the infection and effect a cure.

DISINFECTANTS FOR ABORTION

Animals that have aborted should have their after-births removed as soon as possible and burnt up. But the removal of a retained after-birth is not ta work to be reshly undertaken by the inexperienced. If abortion occurs during an early stage of pregnancy, the after-birth is usually passed out with the young. At a later

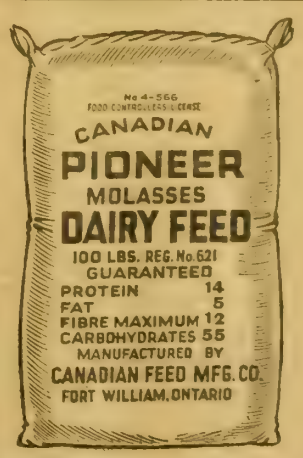
CANADIAN PIONEER STOCK FOOD

A SICK horse, cow or in fact any stock is worse than an engine with a poor cylinder, because it takes longer to cure and causes greater worry. Prevent your stock from becoming "off their feed" by using a stock food of known value.

Right on our bags we give the per cent value of the contents. (Note the illustration herewith.) A proper mixture is as necessary to your stock to get the best results, as a proper variety of foods is to yourself. Stock foods are the happy medium that solves this difficulty.

Write us for full particulars, circulars, etc. Supplies kept for immediate shipment at our branches.



Some of the Canadian Pioneer Stock Foods :

Canadian Pioneer Molasses Dairy Feed.
Canadian Pioneer Molasses Fat Maker.
Canadian Pioneer Hog Meal.

stage it is almost invariably retained, and in those herds in which contagious abortion is present, but in which the calves are carried full term, retention of the afterbirth is frequently the only symptom of abortion. When this failure to promptly pass the afterbirth is observed in several members of a herd, it is almost conclusive evidence that the disease, commonly spoken of as contagious abortion, is present.

Removal of After-birth

It is almost a physical impossiblity to completely and thoroughly remove the retained after-birth of contagious abortion, and many good animals have been ruined by attempts to do so. In the present state of knowledge the best that can be done with a retained after-birth is to keep the outside gentials as clean as possible with antiseptic washes, to wash out the vagina daily with an antiseptic wash so as to remove accumulated decomposing material. For an antiseptic to wash the outside gentials and tail as well as the limbs down to the hoofs, use a two per cent. solution of creolin or a half per cent. solution of lysol, until all discharge from the vagina has disappeared. Cows that have aborted should not again be bred until two or three months have elapsed, so as to prevent extension of the infection, and afford a better chance of becoming pregnant after. Even cows and heifers on infected farms, though apparently healthy, should be kept clean with the disinfectants around the after parts, about the tail and external gentials.

Regarding the after-birth itself, Geo. M. Potter, of the Kansas State College of Agriculture, says: "It should be pulled on gently by grasping it with the hand in the vagina and as close to the neck of the uterus as possible, and it is to be removed only when it comes away easily. It may be necessary to repeat these manipulations daily for several days; patience and perseverance, combined with the skill of experience, will bring the best results. Under no circumstances should force be used, nor should a portion of the after-birth be removed, because as stated heretofore, as soon as the after-birth no longer hangs through the neck of the uterus the latter will close and imprison the remaining portion so that it cannot be removed, but be slowly absorbed, leaving the animal's health permanently ruined and her breeding power destroyed.

"It is not the idea to convey the impression that ideal results will be obtained from the foregoing treatment. If properly carried out, though it requires severe and exacting labor, it will give better results than any other line of treatment practised at the present time."

To Guard Against Infection in Male and Female

It is recognized as impossible to absolutely disinfect the gential organs, but by applying disinfectants it is impossible to reduce the vitality of all germs, and especially those causing ordinary infection, so that nature will have an opportunity to effect a cure. Strong disinfectant injections should never be used, as they do more harm than good owing to their corroding effect.

Immediately after abortion occurs the cow should be washed out with from a few pints to a few gallons of lukewarm disinfectant solution. The amount will vary, as a rule, much less being required when abortion has taken place early in pregnancy. The general rule is that the washing out should be continued until the solution comes away clear.

With the male the long hairs at the opening of the sheath should be kept clipped as short as possible, and the area around the opening should also be well washed with soap and water. The interior of the sheath may be disinfected with the same class of agents as previously recommended for the cow. The number of washings also vary greatly. If the infection is slight, as indicated by little or no discharge, one washing may be sufficient; if there is much discharge, as is generally the case with the cow, the washing should be repeated daily.

In all this work it is of prime importance that the strictest cleanliness be observed, and the operator's hands must be thoroughly clean before commencing the work of disinfection.

The following disinfectants may be used for internal washings: (1) A one-half of one per cent. water solution of carbolic acid, which for practical purposes may be made by adding a teaspoonful of carbolic acid to one quart of water. (2) A one-fourth of one per cent. water solution of compound solution of cresol, being one teaspoonful to one-half gallon of water. In some instances, especially immediately after calving or abortion, even such weak solutions cause the animal to strain violently. In that case it is probably better to use (for a few days) a salt water solution made by adding salt to tepid water in the proportion of a smooth teaspoonful of salt to a pint of water.

FEEDING FOR BETTER WOOL

There are few details of the sheep business more worthy of the interest and study of the farmer than the subject of increased and better wool productino and just in proportion as he brings his mental and physical energies to bear along these lines will he reap his infiiancial reward. It is only within recent years that practical sheep breeders and scientists have realized the relationship that exists between feed consumed and wool production. It is now known that a well fed sheep produces both a heavier and a better fiecee than an under-fed one and experiments have proved that the extra weight and quality of wool pays for the extra feed, besides giving a heavier and more thrifty sheep. When a sheep is well nourished and thrifty, the wool fibre pushes out strong and full, and there is sufficient flow of oil from the root to keep it bright and smooth, but when poorly nourished, the wool fibre is poorly nourished also, and it is thin, weak and dull. The man therefore who wants to produce either much woo or good wool must keep his sheep well fed. Though care is necessary at shearing time to produce a clean marketable article, the crop of wool must get its proper attention throughout the year before the highest profits can be derived from the industry.

LOUDEN

BOOKS FREE

Louden Architectural Service

The most important feature of your barn is the plans you make before you start building. Lay your plans properly and you will have taken the most important step towards having a barn exactly suited to your needs.

Get the Louden Plan Book, 112 pages, crammed with the latest and best possible information on barn planning and construction. Whether you are remodelling, or building, the Louden Plan Book will guide you to correct arrangement, construction and ventilation.

But the best planned barn can give you satisfaction only if furnished with fittings that reduce labor, save time and lessen expense, thus tending to increase your profits, satisfy your hired help and keep the boys on the farm.

Time, Labor and Money Saving Equipment

The new Louden Catalogues shown above are full of just the information you need in order to intelligently determine just what kind of equipment you should have.

No better written, or nicer printed and illustrated catalogue of real money, time and labor-saving devices, has ever been printed in Canada; 135 pages of the most practical, commonsense information. Don't fail to fill in the coupon and get these catalogues free by return mail.

SEASONABLE VERSE

Mary had a little lamb
In days of long ago;
It followed her most everywhere—
At least, the rhyme says so.

It even went with her to school
And used to romp and play,
But things would be quite different
Were be alive today.

I've never heard that little Mary
Packed along a gun,
Nor have I heard that she
Invoked the law on anyone;

And so I'll say that Mary
Must have been a clever kid
To guard her lammie from the naughty
Dogs the way she did.

How fortunate that Mary
Didn't live in Chelsea, Maine,
Where all her careful watchfulness
Would surely be in vain.

Poor little lammie couldn't shake
His tail three times I bet,
Before those nasty poodle dogs
Would have him killed and et.

THE HORSE

HOW TO GROOM AND CLEAN FARM WORK HORSES TO FIT THEM FOR THEIR DAILY TOIL

There is quite a lot of ink used in bulletins and in the agricultural press generally, in describing how a horse should be fed, while very little is ever used in setting forth how he should be groomed. Though this detail in the management of horses does not apparently hold the same important place in horse management literature, it is, notwithstanding, one of the most essential duties of the horseman.

There is more economy in horse power, due to the regular and proper methods of grooming than the average horse owner knows, if his usual neglect of that operation is any evidenc eof his knowledge. Spasmodic fits of grooming, a day or so after the horse has been sweating heavily, and looking so wretched that something has to be done to improve his appearance, does not count for much in horse management. Many men are under the impression that an idle horse does not require grooming; they do not realize that if the horse is properly cleaned every day during the winter months, the spring moths' duties are lightened for the horse and his caretaker alike.

More work will be accomplished on the same feed ration, and the horse will keep in better health if regularly groomed throughout the year.

The Value of Grooming

There are only a very few of the men owning horses who really understand the art of grooming. A really good groom has more influence on the value anad popularity of horses than even a breeder of horses who prides himself solely on the blood lines of his animals. It is one thing to breed horses, but it is another thing to have them feeling good and fit, which constant grooming and cleaning will do.

A horse is never in the highest state of health unless the pores of his skin are kept free from the accumulation of scruf which forms whenever he sweats. The object of grooming is to remove this obstruction, as well as to brace the nerves of the surface by the friction of the brush. This grooming should be done daily, even if the horse has not sweated, and it should be repeated whenever he comes in from work. This will necessitate the removing of the harness at noon, a proceeding that is not common in Canada. In Scotland the custom is different ,no farmer ever allows the work horse to stanad at noon with the harness on. The horse gets two hours at mid-day, from 11 a. m. to 1 p.m., and one of the hours is spent by the horsemen in grooming.

The cleaning of a horse that comes in from work will vary according to the condition of the animal when brought in. It will depend on whether he has been sweated anad has become cool again, or if he is still wet or has enough exercise to keep him warm, or has been driven over muddy roads. A horse coming in wet and dirty after work should never be left in that condition until next day. There should be a deep steady pressure of the brush into the roots of the hair, so as to remove all the scruff that collects around them and clogs the pores through which the sweat ought to be allowed to exude freely. A good brush used daily not only gives a polish to the coat, but it brings a secretion of a fine oil, and that latter has a tendency to throw off water, and thus save the horse exposed to rain, from catching cold.

How Grooming Should Be Done

The horse should first be thoroughly gone over with the curry comb. Then taking the brush in the hand nearest the head, which ever side he begins on, the groom should work away at the head and face until he has thoroughly cleaned these parts, carefully clearing out the dust and dirt from the roots of the ears, where it is very apt to lodge, and continually cleaning his brush with the currycomb in the other hand. Next, he should take the neck, turning the mane over to the other side, and then the shoulder and legs, finishing off with a wisp of hay. The hind quarters and flanks should be treated in the same way. In the spring when the coat is being shed, the brush should never be used and the wisp alone should be employed. The brush will spoil the looks of the new coat, so will the currycomb. The currycomb should, in fact, never be allowed to touch the skin of a horse, when the coat is being shed anad is cruel as well as injurious to the apearance.

The mane and tail should be brushed and combed beginning at the lower end, if it is a full one, not touching the top unti lthe bottom is smoothly arranged. A clean sponge should be squeezed out and the nostrils, eyes and anus sponged clear. If necessary the mane may be dampened so that it can be smoothly brushed and combed down on its right side.

Last the legs and feet must be attended to, the legs being washed with a wet brush kept for the purpose and dried with a cloth. Horses' legs should be wiped and dried every night if wet, and when doing this, a lookout kept for any cuts or burises.

It sometimes happen sthat a horse covered with mud is allowed to dry it all on. If the paritcles of mud are few and far between and are already dry or nearly so, they can be removed by friction alone, but if still wet, and in large masses, water must be used to get rid of them and the legs, flanks and body will require a good slushing with brush and water before it can be gotten rid of.

A piece of hoop iron makes a useful scraper and this is the best way to squeeze the water out. The tail, if a long one may be best cleaned by being put in a bucket of water, and washed with the hands. To clean a white or light gray horse whose coat has gotten discolored through lying on dung during the night, a cloth, warm water and soap is the quickest way. If a slight tinge of brown remains this may be gotten rid of by using washing blue, a small bag of which may be dipped into clean water and the skin washed with it, after the soap has been gotten rid of. The quantity required is easily measured after one or two trials.

There are many drugs that will give a gloss to the coat, but their ultimate effect is to diminish the resist ing power of the skin to bear exposure. When grooming is neglected, the horse soon loses flesh and condition and generally deteriorates in health.

COMMON AILMENTS OF FARM HORSES

"Most common ailments of horses can be prevented by a little care and attention on the part of the owner or groom," said Dr. Baker, of Toronto, in addressing a short course of farming held in Eastern Ontario recently. "In my experience," continued Dr. Baker, "there are more ailments brought on in horses by careless feeding than all other causes combined. The feeding of too much hay is one of the greatest causes of these ailments, and the practice is costing the farmers of Canada a large amount of money every year, both in hay wasted and time lost by sick horses, besides veterinary bills and medicine. Until the farmers of Canada reduce by almost one half the amount of hay they feed at present, they are going to have sick and unthrifty horses. Of course that may seem a strong statement, but when one considers the size of the stomach of the horse and then compares it to the bulk of hay generally fed, it is easy to understand. What actually happens to the horse whose manger is filled with hay at night? Well a horse is a peculiar animal. He

Barrett's
EVERLASTIC
"RUBBER"
ROOFING

You can see the quality of Barrett's Everlastic "Rubber" Roofing as soon as you open the roll.

The best of materials, the utmost skill possible in manufacture, and the experience of over sixty years in making high-grade roofings goes into every roll.

Thousands of rolls of Barrett's Everlastic Roofing have been used by the Canadian and U. S. Governments, the leading railroads, and the largest contractors in the country. Dollar for dollar, it is the best "rubber" value obtainable today.

Don't waste your money on poor roofing that will need to be renewed in a short while. It will pay you better to insist on Barrett's Everlastic and see that you get it. The name Barrett is your guarantee against disappointment. You will find it on every roll of the genuine Barrett Roofings.

will not lie down for any length of time if there is anything for him to eat; he will rise through the night three or four times and eat hay. In the morning his stomach is full of hay. Then he is given a feed of grain, but there is no room for it, and when watered the grain is washed out and goes into the manure. It may be ground up and not noticed, but it is there nevertheless, and is largely wasted.

"If given a limited amount of hay at night, the horse will clean it up in a short time and then lie down and rest. There will be no hay in his manger to entice him to rise, consequently he will remain down most of the night. In the morning his stomach will be empty and he will get the benefit of his morning's feed.

"Take for instance horses belonging to fire departments," continued Dr. Baker, "they are fed properly and they are always in high condition and the best of spirits. They work hard and are never sick, the chief reason being that they do not receive large quantities of hay and water. Water is another thing that most horses receive too much of it. Never allow a horse to gorge himseld with water for the more he takes the more he wants and he will keep it up, one pail of water at a time is plenty for the heaviest horse in Canada. It is good practice to give a horse a few swallows of water frequently if driving on the road or working, but do not allow him to fill up with it. Horses should be taught as colts not to drink too much water. They are easily learned and they will not look for it as they grow older.

"Another thing that causes a heavy loss among horses is feeding the same quantity of feed a day when horses are idle, as when working. That is what causes most cases of colic, stiffness or paralysis, scratches, lymphaugitis, and swollen legs. Every horse owner knows how hard some of these ailments are to cure, but they can be prevented by a little care in feeding. Reduce the feed on idle days, Sundays, etc., and feed a bran mash instead of the heavy grain."

HORSE AND TRACTOR

The breeder of good horses has scant reason to lie awake nights worrying about the future. The only man who has reason to fear the onward march of the farm is the one who is wasting his time growing plug horses. Thousands of farms are horse poor with those mediocre animals that a market buyer won't look at. This is the class of horse the tractor is going to eliminate. It is the only part of the horse-breeding industry that the tractor is going to injure.

In the future the horse and the tractor will pull together. They will make a willing team for agriculture. The tractor will supplement and conserve horse power and vice versa and the combination of horse and mechanical co-operation will mean better farming methods and more economical operation of land. The properly equipped farm of tomorrow will employ both horse and tractor power. The land operator will use the one or the other consistent with his needs and the seasons.

The man who is still frittering away his time and energy growing cheap horses might as well face the music. The farm tractor will elbow him and his scrubs out of the way. He should study carefully the "hand writing upon the wall;" it will assure him of the profitable days to come when the scrub only exists in memory.

GOMBAULT'S
CAUSTIC BALSAM

A safe, speedy and positive cure for

Curb, Splint, Sweeny, Capped Hock, Strained Tendons, Founder, Wind Puffs, and all lameness from Spavin, Ringbone and other bony tumors. Cures all skin diseases or Parasites, Thrush, Diphtheria. Removes all Bunches from Horses or Cattle.

As a HUMAN REMEDY for Rheumatism, Sprains, Sore Throat, etc., it is invaluable.

Every bottle of Caustic Balsam sold is Warranted to give satisfaction. Price $ 1.75 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars, testimonials, etc. Address

THE LAWRENCE-WILLIAMS COMPANY, Toronto, Ont.

CURE FOR THRUSH AND WORMS

I have a horse that is suffering from hoof disease. The hoof around the cleft of thefrog is filled with matter that has a disagreable odor. What is the best cure for worms in horses?

The hoof of your horse is affected with thrush. It is caused by standing in water and filth, such as wet straw and stable refuse; frose bite or neglect of systematic cleaning of the hoof of all mud or baked dirt. Place the horse in a clean stable with a dry floor, well littered. The seat of the disease foot should be cleaned, the excessive growth removed, and calomel applied as follows: Calomel, half an ounce; sweet oil two ounces; mix and spread on a piece of lint or oakum and insert in the cleft of the frog, and over the other diseased parts.

For intestinal wounds use a vermifuge made as follows: Oil of turpentine, two ounces; oil of male fern, one drachm; linseed oil, half a pint. Give after a purge and on an empty stomach. Repeat the dose after a week, followed with a drachm of powdered sulphate of iron in the feed.

For thread worms the treatment should be by injections up the rectum, made of oil of turpentine, two drachms; linseed oil, one pint. Use every morning for a week.

CARE OF BROOD MARE

Let the brood mare live as near a normal life as possible. Given a sufficient amount of mixed, wholesome food, such as oats, bran, corn, alfalfa, prairie hay, oat straw, corn fodder, carrots, rutabagas, she will balance the ration. Allow no valuable mare to be pampered, for those that have the freedom of all out-of-doors and live on nature's pastures go through the ordeal of pregnancy and parturition with the least inconvenience and danger. Regular exercise is absolutely necessary, an energetic high-life animal will take enough exercise if turned out for several hours each day. For those not so ambitious forced exercise is necessary, place in harness every day for several hours. Avoid all severe exertion and injuries, as far as possible. Each pregnant mare deserves a stall to herself. As the period of parturition approaches watch conditions of bowels closely and reduce the diet, remove the mare from the work-horse stable (which is a hot bed of disease microbes); if possible place her in a clean, disinfected maternity stable, with an abundance of sunshine, fresh air and clean straw. Keep the mare and stable scrupulously clean at this time, have her well groomed each day, no dirt on belly, banks or legs and wash with good disinfectant, especialy the udder, before allowing the young to nurse.—N.D.A.C.

If you can't get things to coming your way try some other way.

Julicious feeding does not mean excessive feeding ,but feeding to get the largest net returns.

John Lumsden, of Ottawa, writes about his Cletrac Tank-Type Tractor:
"Besides pulling a three-bottom 12-inch Cockshutt Plow in old sod full of Scotch grass, I have run my 30-inch Threshing Machine with Blower, and also filled my silos, using a No. 3 Blizzard Corn Cutter."

More Land for Crop—
and Every Acre Worked Right!

That's when the farmer makes big money—when his farm is in good shape—when every acre is under crop and the yield is big, because the land is well worked.

With a Cletrac Tank-Type Tractor a farmer can get his place in the best possible shape.

Wet weather or hot weather does not hold field work back. Every acre he wants to put under crop is ploughed in quick time. Discing and harrowing are done—and done thoroughly—at the right time.

The Cletrac is the tractor that carries its own tracks like a "Tank." It does not pack the soil. It travels 3½ miles an hour on ploughed or wet land *without slipping.*

It has 12 h.p. at the draw-bar—for hauling in crops, as well as for field work.

At the belt pulley—20 h.p. Ample for any job on the farm, from silo-filling to operating a junior thresher.

Low set—will work under trees. Handles easily. Swings in small radius.

Figure what a difference the Cletrac will make on your place. See it at work. Write for our two interesting booklets "Our Owners Say" and "Selecting Your Tractor."

Butter Parchment at Farmer Office

POULTRY.

AN UNOFFICIAL "RECORD OF PERFORMANCE FOR POULTRY

A review of the present and prospective egg and poultry situation points strongly to the fact that the economical production is going to be an increasingly important factor in meeting the competition of the world on the export market.

While the cost of unit production in the poultry busines is affected by many conditions, it has been clearly evident for some time that no factor has a more potent bearing on cost than the productiveness of the individual bird. It requires a certain number of eggs to pay for the feed fed and labor expended. The number required varie acording to the cost. Profitable production can only be obtained by having a safe margin of eggs over the equivalent of cost, the more eggs per bird the greater the remuneeration.

Increased production both in the individua land in the flock has been shown to be largely a matter of breeding. The Record of Performance for poultry is a policy planned to give point, direection and encouragement to the breeding of poultry along lines of greatly increased individual and flock production.

The minimum record to permit a bird to qualify in the Record of Performance has been set at one hundred and fifty eggs in fifty-two consecutive weeks and for qualifications in the Advanced Record of Performance a minimum of two hundred and twenty-five eggs in fifty-two consecutive weeks. The weight and quality of the egs during the month of April shall not be lower than that of the grade "Specials" in the Canadian Standards.

Certificates will be issued for all birds qualifying in the Record of Performance. The birds that qualify shall also be identified by a sealed band and the number registered.

The Record of Performance for poultry is to be divided into two parts, "A" and "AA".

Record of Performancee "A"

This is to consist of the inspection of trap-nested flocks on individual poultry plants and shall be similar in form to the Record of Performance for dairy cattle. It will be open to any breeder that wishes to enter his flock and will be under the supervision and inspection of officers of the Poultry Division of the Live Stock Branch.

Record of Performance "AA"

This will consist of the conducting of tests under Government supervision and on Government or neutral ground, for the purpose of obtaining an official record by actual trap-nest results.

This official tesst may be conducted by either Federal or Provincial Government or Colleges and may be secured by:

1. "Laying Tests."
2. "Laying Contests."

Record of Performance "AA" will be under the supervision and direction of officers of the Poultry Division of the Experimental Farms Branch.

Official Requirements of Entrants in Record of Performance "A"

All entries shall be made upon forms supplied by the Department and subject to Departmental rules and regulations.

Applications for entry must be dated and mailed one month in advance of the date it is desired the record shall commence. For purposes of organizations during the present year 1919, aplications will be received for individual birds to commence their records on the 1st of September, the 1st of October, the 1st of November and the 1st of Devember. There shall be an entry fee of one dollar (1) for the first ten birds entered and five cents (5c.) for each additional bird.

Defies the Breeze and Bluster

Whether in cutter or auto, drivers and carters speed undaunted through winter's roughest weather in Atlantic Underwear.

Postmen, policemen, truck drivers, farmers—all men who work in the great out-doors, find Atlantic underwear the best for winter wear.

A heavy, comfortable stout wearing garment that the cold cannot penetrate, Atlantic underwear means health and comfort to thousands of red-blooded, out-door workers.

Sold in five different weights and qualities. Our lower-priced lines are not equal to the more expensive ones, but each is guaranteed to be the best value of its class. Compare them with others of like price and see for yourself.

THIS TRADEMARK GUARANTEES LONG WEAR

ATLANTIC UNDERWEAR
UNSHRINKABLE
ATLANTIC UNDERWEAR LIMITED
MONCTON, N.B. 7

Only pure bred stock of standard varieties and free from standard disqualifications may be entered.

The minimum entry shall not be less than ten birds from any one flock.

All stock entered shall be trap-nested during the period of the official test, which in no case will exceed fifty-two weeeks.

All equipment on inspected plants shall be kept in a clean and sanitary condition.

Records shall be kept posted up to date at all times for the information of visiting inspectors.

Only eggs actually found in trap-nests shall be counted.

Entrants shall use prescribed record forms. These shall consist of weekly house records and monthly or yearly book records. The weekly records shall be mailed regularly by the breeeder to the Department.

The fullest information shall be given to official inspectors and any entrant who offers opposition renders his entry liable to cancellation.

Methods of Inspection

All flocks will be placed under systematic, periodic, unannounced inspection. Official visits will be at irregular intervals; they may average once a month or more frequently as occasion demanded.

The general health, condition of the stock, current productiveness and the ordinary physical and visual tests of egg laying will be used by inspectors in checking the accuracy of the records.

Inspectors required for the Record of Performance will be chosen by Special Civil Service Examination.

In case of an inspector's decision being questioned by the owner of the flock, another eexamination by the inspector may be given or, at the option of the Department, another inspector may be sent. In either case a second inspection by the same or another inspector will be considered final.

For particulars in reference to Record of Performance "A" inquire of the Poultry Division of the Dominion Live Stock Branch. Ottawa.

Record of Performance "AA".—General Information

Laying Tests and Laying Contests both will be used as mediums to obtain the qualifications for entrance to the Record of Performance. The major portion of tests and contests will be conducted by the Experimental Farm upon its Central and Branch Farms but Provincial Departments of Agriculture and Colleges also may conduct these.

Laying ests are distinguished from contests in that they are not competitive, but merely for the purpose of ob-

RELIEF AT LAST

taining an official record of production. At present complete arrangements are made by the Dominion Experimental Farm to hold these tests at all of its Farms throughout the Dominion.

The laying contests will be conducted this year as follows: World's Contest at Central Experimental Farm, Ottawa, on the Branch Farms at: Charlottetown, P.E.I., Nappan, N. S., Cape Ruoge, Que., Brandon, Man., and Indian Head. Sask. All contests have ten birds to pen and start November 1st, continuing ofr fifty-two weeks.

Aplications for both tests and contests on the Experimental Farms must be made before September first, but as the number which can be accommodated is limited, it is advisable to make application early. Entry blanks, Rules and Regulations, may be secured from the Poultry Division, Experimental Farm, Ottawa.

All birds in tests or contests that qualify for Record of Performance or Advanced Record of Performance will receive the certificate of registration.

WHAT AND WHEN TO MARKET

Need of Seasonable Marketing

Poultry produce should be marketed as soon as it is ready. The sale of eggs conforms to this rule better than does the sale of meat, for the bulk of poultry meat is sold within a few weeks in the fall. One of the reasons for the regular slump in prices in the fall is because so many hold all the poultry they have for sale until that season, whereas it would be better if sold when ready any time during the year.

What To Market During the Summer Months

Though the summer months may not be the months in which there is the greatest proportion of poultry meat for sale, there is considerable whch can be disposed of between July and October. Among these may be enumerated the following, coming largely in order of readiness—cock birds, hens, broilers, green ducks and roasters.

Cock Birds

As soon as the breeding season is over, all males should be disposed of. Infertile gegs keep better than fertile eggs. There is no use in feeding the extra males when they might be turned into money and the feed saved, and it does not pay to feed them for another breding season.

Hens

When the hatching season is over, a number of the breding females may be selected and marketed. Those that have stopped laying had better be culed out, and those over-fat and old. At this time of the year hens bring a higher price than they do in the fall.

Again, later, another selection may be made. Hens that are beginning to moult, say during July and early August, might just as well be sold. The good hens, the hens you want as next years breders, are not the ones that moult early, but the ones that moult late in the fall.

Broilers

As a rule, where one is situated near a good market, be that a city or summer tourist trade, broilers will bring a better price than the same birds might bring in the fall as roasters, and the feed, room and trouble are saved during the summer months. The only time to sell Leghorn cockerels is when they reach about two pounds each in weight.

Green Ducks

The only time to sell ducks profitably is when they are from ten to twelve weeks old. That covers the period of cheapest production. Usually a green duck will bring as much per duck in the fall and the expense is very small in proportion.

Roasters

The bulk of young cockerels will no doubt still be kept until fall and sold as roasters, and it tis not supposed that every person is in a position to dispose of them as broilers.

Crate-feeding Anything

Make the rue that none goes off your place without special crate feeding. The finishing touches pay best and the farmer who markets poor cockerels is deliberately throwing away a large percentage of his profits. Crate feed for three or four weeks before killing, and in the killing and marketing follow directions given in Bulletin No. 88, Experimental Farm series, which may be had on application.

Culling

The time for culling is always now. Whenever you see a bird that is not doing well, pick it up and put it into a crate. Make sure that it is fleshed, and then kill it for your own use or for sale. Start culing as soon as the chicks are out and cul every day, or whenever you se anything that needs culling. Keep the buds growing throughout the summer. Give them plenty of feed, shade and water and lots of milk.

Keep the chicks growing throughout the summer. A stunted chick is unprofitable. Sow green crops for shade. The hot sun on growing chicks stunts them. Look for lice and mites. Spray them often with a good disinfectant. Give the henhouse its annual house c leaning and white washing.—F. C. Elford.

Shorten the Molt
HENS can't lay when molting, they are too busy making feathers. And at this critical time they are in danger of contracting disease because of weather changes, lack of plumage and weakened condition.
Hurry your hens through the molt and get them back on the job.
Pratts POULTRY REGULATOR
puts new vigor into weakened molting hens, gives them strength to resist disease, carries them quickly and safely through the molt, and starts them laying with no serious loss of profits.
Speeds up the pullets, too, and gives you more eggs when prices are high.
"Pratts" supplies those necessary tonics, appetizers, digestives and laxatives which are lacking in the usual poultry ration.
For nearly 50 years the favorite of successful poultrymen everywhere.
Try it at our risk.

YELLOW SHANKED HENS

Where facilities have been provided, enabling the poultryman to become familiar with the laying records of each individual hen, it has been found that in the yellow shanked breeds the hens that are consistent layers lose their shank color. This shank color comes originally from pigments in various foods such as yellow corn and is carried by the blood and deposited in the shanks and beaks, and even in the plumage, if there is a surplus of pigment. When a hen lays heavily, the yolk of the eggs require all the pigment and the deposition in the shank ceases. The pigment that is already in the shanks wears away with the epidermis, or else is taken up by the blood and carried to the yolk, where it is deposited. This causes the shanks to fade, and the greater the egg production the less color will be found in the shanks. When the hen ceases to lay, the color will return. When selecting the layers in the flock, this is an excellent criterion to use in eliminating the unprofitable hens.

The hen's greatest profit-producing period is during the first and second years, and unless a hen is an exceptionally good breeder she should be disposed of at the end of her second laying season, before beginning to molt. Few eggs can be expected until the pullets are matured.

Our hearts in glad surprise,
To higher levels rise.

Honor to those words or deeds
That help us in our daily needs,
And by their overflow,
Raisè us from what is low.
—Longfellow.

A SUCCESSFUL EXPERIMENT

(By Gordon Carruth)

He put his paper aside abruptly, rose and walked down the leaf-strewn path to the other bench, where the girl was sitting.

"Would you like to try an experiment?" he asked quietly, standing with hat in hand before her.

She looked at him for a moment unsmiling, her expression neither inviting nor repelling.

"Perhaps," she said at length.

He sank into the seat beside her. "It is something I have often wanted to try," he said slowly. "Here are we two, perfect strangers in a city of five millions, and never likely to see each again after we leave this chance meetinv place. We have sat here half-anhour, each pretending to read, or to watch the squirrels, or the falling leaves, or the misty golden sunshine out there on the field, but each examining and appraising the other when the other wasn't looking.

"Now, this is the experiment: We have each gained a strong first impression of the other. Let us with absolute frankness, tell each other what those impressions are. Let us do what friends cannot do—speak without reservations, made for fear of hurting each others feelings."

She sat without speaking for a moment after he had finished, gazing thoughtfully out at the warm expanse of autumn-tinted park.

"But why?" she asked at last. "I am not sure that Burns was right. Perhaps it is just os well that we can't see ourselves as others see us."

"That" he said, "makes it an experiment. It will be a new experience. I want to know exactly how I look in the eyes of a stranger, however much the knowledge may hurt. Have you ever felt that way?"

"Yes," she said. "I have. Eeeryone does, I think."

We"ll, I'll tell you, if you will do as much for me."

Again she hesitated and sat silently watching a gray squirrel that, untroubled by self-consciousness, was busy burying a nut.

'Well,' she said finally, "you first."

"The fact that I came over here and proposed this experiment to you at all shows that I thought you a sensible girl," he began slowly. "You impressed me as befng neither a prude nor a flirt. You are pretty—I dont' need to tell you that—but it has not spoiled you. You are rather thoughtful and studious, and you have a genuine feeling for the beauties of nature—something which too many girls just pretend to have. You are not above, I believe, taking interest in babies and embroidery, although you know what is going on about you in the world and read something besides the woman's page in the newspapers. You don't work for your living, and your home is one of the comfortable houses in the seventies. You see a good deal of the healthy side of life, but you keep healthfully busy at serious things. You are probably a suffragist in a quiet way, and you are also interested in some form of social or philanthropic work, which you do not treat as an heroically assumed duty, And—

He was interrupted by the girl's low laughter. "Why not say that I have all the good qualities, and be done with it?" she asked. "Your impression is certainly not very accurate. Let's see if I can do better.

"You it seems to me, have many of the excellent qualities that you are attributing to me. You are nothing of a sport, but are a rather serious-minded young man, somewhat too much given to introspection. You are not bad looking, and you impress me as having a good deal of common sense. You are about twenty-five, and you are one of our rising young professional men—an architect, perhaps, or an engineer of some sort. You read a good deal, and, when it comes to newspapers, something besides the sporting pages. You also live in one of the better homes in the Seventies or the Eighties, and you are a confirmed New Yorker. There, how is that for a snapshot portrait?"

He did not answer at once, and they both sat silently for a few minutes. Presently he said gloomily:

"My experiment has failed, I'm afraid."

"Of course," she assented gently. "It was bound to. It shows of how little worth a first impression is anyway. You wondered if the defects that you see in yourself were apparent to others, and you are half disappointed that they are not, for you do not like the idea of wearing a mask. Isn't that it?"

"Yes."

"And yet you must have known, except in moments of self-depreciation, that you make a favorable first impression; and I know that I do, conceited as that may sound.

"All right," he straightened up abruptly. "Then we come to the second part of the experiment. We will now tell just how badly each of us is mistaken."

"Well—" she hesitated. "We can try it but that also is a pretty hard thing to do."

"Listen to me first," he answered, "while I tell you what a poor judge of character you are at first glance. I may have a sense of humor, but it doesnt work very well. I am gloomy, pessimistic and am rapidly developing into a chronic grouch. I am not one of our rising young professional men; I am a clerk in a large mercantile house, and there hasn't been anything startling in my rise yet. I may have common sense, but it doesnt keep me from making a fool of myself about half the time. I lack purpose and determination. I may be domestic by nature, but that's all the good it does me. So far from living in a brownstone house in the Eighties am I that I live in a single room down in the Twenties. I come from Michigan and am a comparative stranger in New York. I read a good deal, it is true, and you are right about the sporting page, but I don't believe that I ever had an original idea in my life. And—well, I might go on at considerable length, but how do you like the retouched portrait so far?"

The girl was laughing at him again. "I think the portarit none the worse," said she; "especially since you are clearly in a mood for self-disparagement. Let me alter your portrait of me a little. I hope that I am sensible, Im not a flirt, but I'm not so sure that I am not conceited. I like babies and embroidery, but Im not interested in charitable work and I do read the woman's pages in the newspapers. I don't live in a brownstone house in the Eighties either, but have a room up in the One Hundred and Eighties. I earn my living by teaching a class of little Greek, Italian and Russian children down in an East Side school, and I dont move in any other society. I have a bad temper; I'm afraid my pupils suffer a good deal at times. No doubt, I am more studious than most girls but I like the movies and candy and all sorts of frivolous things very much. Now how do you like the retouching?"

"Well," he admitted gravely, "I rather think it improves the portrait; it makes it so much more human."

They fell silent again watching the sunshine on the colored trees.

"You are quite right about one thing," said the girl presently. "I love the trees and fields and the sky. I was brought up in the country, and I don't believe I could stand it here in these endless miles of brick and stone is it were not for the park."

"I come here often myself," the man said. "Do you?"

"Every Sunday afternoon. I like this spot best of all; the view is so beautiful."

"So do I."

The sun had left the trees and they could see the lights of the city twinkling like brilliant stars."

"Do you know," said the man, rising. " think my experiment is not going to be a failure, after all, though it has not resulted as I expected."

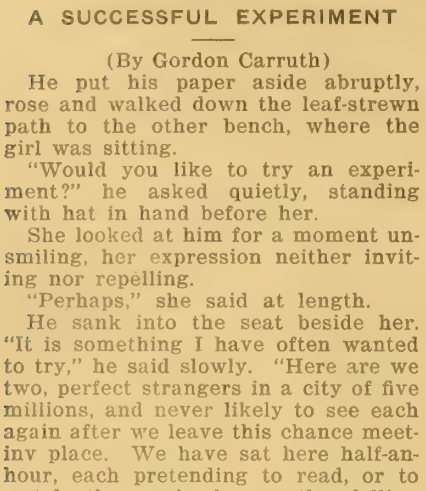
"Perhaps it won't," answered the girl quietly.

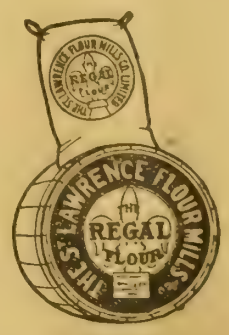
There was a moments' pause. Then —" will say only—goid night," he said.

He turned and walked along the darkening path. As he reached the bend he broke into a cheerful whistle. The girl smiling walked briskly away. She was wondering what she would wear next Sunday afternoon ahi he wa strying to decide if it would be wise to take a box of candy with him.

Orange Nectar

1 quart tea infusion.
Juice 2 lemons.
Juice 2 oranges
1 pint ginger ale.
Very litle syrup (to taste.)





THE care exercised in selecting the wheat used in the making of "REGAL FLOUR" is one of the many efforts which has helped to secure for "REGAL" the reputation—big value in flour.

THE ST. LAWRENCE FLOUR MILLS CO.

Far more effective than Sticky Fly Catchers. Clean to handle. Sold by Druggists and Grocers everywhere.

PICKLES SWEET AND SOUR

Small Cucumber Pickles

Select cucumbers or gherkins not over a finger in length. Wash them carefully, place them in stone or glass jars and cover with the following liquid:

1 cupful of mustard.
1 cupful of salt.
1 cupful of sugar.
1 gallon of vinegar.

Lay as mall plate or round board upon the pickles and weight down with a clean stone. f you raise your own cucumbers pick them every day, wash and dry, and add to those in the jar.

Dresden Pickles

12 cucumbers.
6 onions.
6 green peppers.
6 red peppers.
5 bunches of celery.

Put the ingredients through the coarse cutter of a meat grinder and let them stand in salt and water over night. In the morning rinse and drain well and remove the seeds from the peppers. Add the following liquid to the mixture:

3 pints vinegar.
2 tablespoons of white mustard seed.
1½ pints of sugar.
2 tablespoonful of celery seed.

Cold Relish

1 peck of ripe tomatoes that have stood over night.
4 green peppers seeded and chopped.
2 cupfuls of chopped celery.
5 ounces of white mustard seed.
5 chopped onions.
1 cupful of salt.
4 cupfuls brown sugar.
5 cupfuls of vinegar.

Stir the ingredients together thoroughly and put up cold in cans.

French Pickels

1 peck of green tomatoes sliced.
6 large onions.
½ cupful of salt, sprinkled on mixture.

Let this stand over night, drain thoroughly in a colander, boil fifteen minutes in two quarts of water and one pint of vinegar. Take out and drain. Boil until tender in four quarts of vinegar ,two pounds of sugar and half a pound of white mustard seed. Tie one tablespoon each of all kinds of spice in a muslin bag and cook in the mixture. Put the pickles in a stone jar.

Tomato Ketchup

2 quarts of tomatoes sliced, 2 onions sliced. Cook together and rub through a sieve. Add the following ingredients:

2 cupfuls of vinegar.
2 cupfuls of sugar.
1 tablespoon mustard.
1 tablespoon cloves.
1 tablespoon of cinnamon.
1 tablespoon salt.
1 tablespoon pepper.

Bottle after cooking an hour.

Sweet Pickled Pears or Peaches

5 pounds of fruit.
3 pounds of brown sugar.
3 pints of vinegar.
1 ounce stick cinnamon.
½ cupful whole cloves.

Boil the sugar, vinegar, cloves and cinnamon twenty minutes. Dip the peaches quickly into hot water and rub off the down with a clean coarse cloth: Put half of the fruit into the sirup and cook until soft, remove to glass jars with a perforated skimmer, and cook the remaining fruit in the same sirup. Boil down the sirup when the fruit has been cooked and pour it, scalding hot, over the fruit. Seal.

Pickled Onions

Peel small white onions and let them stand in strong brine for four days, changing the liquid during that time twice. Heat more brine to the boiling point, add the onions and boil three minutes. Remove the onions, throw them into cold water and leave four hours. Pack them into jars with whole mace and white pepper-corns and cloves. Cover with scalding vinegar containing one cupful of sugar for every gallon. Bottle while hot. These may be used in a month, but are better after the third month.

Tomato Pickle

1 peck of green tomatoes.
2 heads of cabbage.
1 dozen onions.
1 dozen green peppers.
1 dozen red peppers.

Cut and salt overnight, then drain in the morning. Add:

1 ounce celery seed.
3 pounds of brown sugar.
4 ounces of mustard seed (yellow.)

Cover with vinegar and cook.

Pickled Beets

Select firm beets, wash well and put on to cook until tender. When thoroughly done remove the skins and slice about a quarter of an inch thick and pack in jars. To one gallon of vinegar add two cupfuls of sugar, let come to a boil, pour the beets and seal. These are delicious for winter days.

APLLES

The steaming method is usually the the best for canning apples. After the apples are washed and peeled, quarter or halve them and pack them in glass jars in a wash boiler on a false bottom of shingles or wire screen, surround them with a few inches of warm water and steam them until the apples are tender. This usually takes about an hour for quart jars and twice as long for two quart jars.

Remove one jar at a time, put a new rubber in place and fill the jar to overflowing with a hot sirup made by boiling together for fifteen minutes sugar and water in the proportions of a quart of sugar to a quart of water. Seal it at once. Sliced lemon or some other flavoring matter may be added if desired.

If the apples are very hard they should be canned by the boiling method. Cook the quartered apples in clear water until they become tender, then drop them into a thin sirup and boil them gently a few minutes longer. Put a new rubber in place on a sterilized jar, fill the jar to overflowing with the fruit and boiling sirup and seal it at once, using a sterilized cover.

Because most apples contain a large quantity of pectin, they have long been the housewife's favorite fruit for making jelly. Pectin is a substance that makes swetened fruit juice harden into jelly when it is boiled. Late fall and winter apples in particular produce jelly of fine flavor and rich color. In making apple jelly, wash the apples thoroughly, remove any parts that may be decayed or soft and also the blossom ends and stems. Do not peel or core the apples, but cut them into small pieces and place them in a preserving kettle. Barely cover them with cold water. Stew them slowly until they are well done. Turn them into a jelly bag and drain them overnight without pressure.

In the morning measure the juice, which should have a rich color and be free from pulp, place it on the fire and boil hard for several minutes

PAIN ACROSS KIDNEYS

Was So Bad

Had To Go To Bed.

Women are the greatest sufferers from weak, sore, lame and aching backs, owing to the continual stooping, bending and lifting so necessary to perform their household duties.

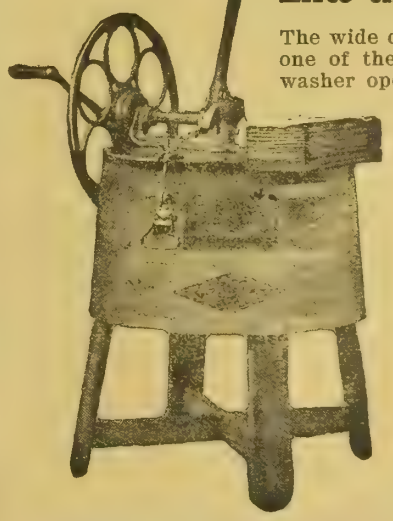
On the first sign of any weakness of the back Doan's Kidney Pills should be taken, and thus prevent serious kidney troubles which are sure to follow if the bad back is neglected.

Miss Gladys M. Buckler, Tatamagouche, N.S., writes:—"I feel it my duty to let you know what Doan's Kidney Pills have done for me. I suffered for years with a sore back. I was so bad I had to take to my bed sometimes with the pain across my kidneys. I went to two different doctors; they treated me, but I got very little relief. I saw Doan's Kidney Pills advertised for sore back, so sent for two boxes, and before I had the first one taken I felt a change. I cannot recommend your medicine enough."

Doan's Kidney Pills are 50 cents a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited. Toronto. Ont.

KING COLE
TEA
KING COLE
ORANGE PEKOE
TEA
KING COLE PURE INDO-CEYLON TEA
Held High in Public Esteem
WHETHER you are a user of KING COLE Orange Pekoe or KING COLE Indo-Ceylon Blend, you know that the quality has been consistently maintained. That alone explains the steadily increasing sales.
They are dependable teas.
Perfectly packed in bright lead foil and price marked on every package.

Lifts the Burden Off Washday



The wide opening top of the "Maxwell" is only one of the many special features — no other washer opens right up in this way.

Maxwell

"High-Speed Champion" Washer

Gives heaps of room for work. Has a crank handle at side, and a top lever. You can use either. Runs almost by itself—and its so easy to work a child can wash with it. No rubbing—no bending over hot, steamy tubs. Get a Maxwell High Speed Champion and have your washing done in half the time!

MAXWELLS LIMITED

Dept. X. ST. MARY'S, Ont.

Suffered from Constipation

FOR TWO YEARS.

If the truth were only known you would find that over one-half of the ills of life are caused by allowing the bowels to get into a constipated condition. When the bowels become constipated the stomach gets out of order, the liver does not work properly and then follows the violent sick headaches, the sourness of the stomach, belching of wind, heartburn, water brash, biliousness, etc.

Keep your bowels regular by using Milburn's Laxa-Liver Pills.

Mr. A. Roder, Hastings St. E., Vancouver, B.C., writes:—"I desire to express my thanks for what Milburn's Laxa-Liver Pills have done for me. I had been suffering from constipation for two years, also had a bad cough and headaches. I tried all sorts of cures and remedies, but got no relief until I was advised to try your pills. I got great relief after the first few doses."

Price 25c. a vial at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont

to evaporate part of the water. Heat as much granulated sugar as there was of measured juice, and while it is still hot add it to the boiling juice. Continue the boiling until it jellies when cold; this should be only a few minutes after the sugar is added. Pour the jelly into glasses. When it is entirely cool cover it with melted paraffin, label the glasses and store them in a cool, dry place.

A Fine Foundation Jelly

By combining apples with small amounts of the more expensive fruits, such as pineapple, to produce different pleasing flavors, several varieties of jelly may be obtained. Different flavors may also be secured by dividing the jelly into different parts when it is taken from the preserving kettle, and adding to one portion a few drops of vanilla, to a third a pinch of ground cloves, and so on.

Experiments may be made in the following manner with different extracts to see whether they produce desirable flavors: Take out a teaspoonful of the jelly, add to it a drop of the flavoring material, stir the spoonful well, allow it to cool and taste it. If the flavor is pleasing the entire quantity may then be flavored.

Sweet apples make the most delicious preserves, though other varieties may be used with a lesser degree of success. Wash, peel, core and quarter the aples. . Make a heavy sirup by boiling together for fifteen minutes sugar and water in the proportion of a quart of sugar to a quart of water. The denser the sirup, the better the apples will keep their shape. More water must be added whenever the sirup shows a tendency to jelly.

Drop a few apples into the heavy boiling sirup—the preserves are better if the apples are entirely surrounded by the sirup while they cook—and boil them until they turn a rich color and become somewhat transparent. Transfer the apples, but not the sirup, to a sterilized jar; then add more water if the sirup is beginning to jelly and cook more apples. Continue the process unti lthe apples are all cooked. Then pour the remaining sirup over the preserves and seal the jars.

Sweet apples and quinces may be combined to make excellent preserves. Peel, quarter and core both the apples and the quinces. Steam them until the are very tender. Make a heavy sirup by boiling for twenty minutes water and sugar in the proportion of a quart of sugar to a quart of water. Drop the steamed fruit into the boling sirup and boil it until it becomes a arich red color. Do not stir it. A slice of lemon in the sirup improves the flavor. Put the fruit into sterilized jars, put new rubbers in place, boil the sirup down until it is very thick and pour it into the jars until they overfloow. Seal the jars at once.

Apple ketchup is a foreign dish that is coming into deserved popularity. Peel, core and quarter five pounds of tart apples. Cook them until smooth with a quart of brown sugar and two quarts of cider vinegar. Place the mixture in a crock and add two pounds of chopped raisins, a small mild onion, an ounce each of ground ginger, one tablespoonful of salt and two or three red peppers chopped fine. Mix the ingredients thorougthly and let them stand overnight. In the morning transfer the ketchup to jars without cooking and seal at once. It will keep for years.

An Oriental Mixture

East India chutney is an oriental ketchup with apples as a base. Pare and core twelve sour apples. Peel one mild onion. Remove the seeds nad stems from three peppers. Seed a cupful of raisins and extract the juice of four lemons. Chop the apples, peppers, raisins and onion very fine and mix them together thoroughly. Add the lemon juice, one pint of cider vinegar, two cupfuls of sugar, one tablespoonful each of salt and ground ginger and a quarter of a teaspoonful of cayenne pepper. Cook the mixture another hour, stirring constantly, and then seal it in glass jars.

In these days of canned fruit and preserves and jams, old-fashioned dried apples hardly receive the attention they deserve. Dried apples are not so attractive as the other forms of preserved fruits, but they make up for this, in part at least, by their high food value. In the latter part of the winter, when the supply of preserves and jams runs low, occasional dried apple pies and daintily flavored dried apple jelly afford a welcome change in the menu. To make the jelly place quarts of dried apples in a granite kettle, cover them with water, and stew them slowly for two or three hours. Drain off the juice and measure it. For every pint add three-fourths of a pint of sugar and the juice of two lemons. Boil the mixture until it hardens when cool. Turn the jelly into glasses and cover them.

He Inherited All His Many Troubles

BUT FOUND RELIEF IN DODD'S KIDNEY PILLS

Evidence from Cape Breton that the Most Deeply Rooted Forms of Kidney Disease Yield to Doods Kidney Pills.

Red River, Inverness Co., C. B.—Sept. 7th (Special)—That even the most deeply rooted kidney disease yields to a treatment of Dodd's Kidney Pills is shown by the statement of Mr. James N. Timmons, a well-known resident here. Mr. Timmons says that he inherited his kidney trouble from his parents and suffered from it for six years.

"I used two boxes of Dodd's Kidney Pills and they did me a lot of good," Mr. Timmons states. "If I had followed on with the pills I believe they would have completely cured. I am always glad to tell others how much benefit I got from using Dodd's Kidney Pills."

Mr. Timmons suffered from many of the varios ills that accompany any kidney trouble. He had rheumatism cramps in the muscles, backache, and headache. His sleep was broken and unrefreshing. He felt heavy and sleepy after meals and he was always tired and nervous.

If you have any of these ailments you can be sure your kidneys are out of order or diseased. Ask your neighbors if Dodd's Kidney Pills will not help you.

The most important point to consider in drying apples is the protection of the fruit from flies and other insects and from dust. Peel, quarter and core the apples. Place clean papers on the drying frames, and spread the apples over them evenly in one layer. Cover them well with glass; or if this is impossibe, with mosquito netting. Place the frames away from the road, preferably well off the ground. Allow the apples to remain ni the sun during the day. After they have partially dried, place the contents of three or four frames on one. This will allow fresh apples to be placed on the other frames. When the apples are dry place them in paper sacks and hang them in a cool, dry place.

BEWARE OF FLIES

Flies should be kept out of our houses, killed if they enter them, and prevented from hatching their eggs in stables, manure heaps, swill pails, and other filthy places. They are born in filth, they feed on filthy, they walk on filth, and then with filth sticking to their feet, legs and bodies, they feed and walk on the food which has been prepared for human beings to eat. It would disgust us, wouldn't it, if we saw a fly feeding on the filth of the street, the stable the garbage can, or on something even worse, and then saw the same fly go through the open door or window of our dining room and wipe its feet on the sugar, tangle its legs in the butter, or take a bath in the milk? If we should watch every fly that comes in the house, we would see that most of them come from such filth to the food of our table.

Flies Are Dangerous

Bad as filth is, it is not the worst

I KNOW A WOMAN'S SUFFERINGS

I am a woman.

What I have suffered is a far better guide than any MAN'S experience gained second-hand.

I know your need for sympathy and health.

And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.

Are you unhappy, unfit for your duties? Write and tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.

If you suffer from pain in the head, back, or bowels, feeling of weight and dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creeping feeling up the spine, palpitation, hot flashes, weariness, sallow complexion, with dark circles under the eyes, pain in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your own home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

Read My FREE Offer:

To Mothers of Daughters. I will explain a simple home treatment which speedily and effectually dispels green-sickness (chlorosis), irregularities, headaches and lassitude in young women, and restores them to plumpness and health. Tell me if you are worried about your daughter. Remember it costs you nothing to give my method of home treatment a complete ten days' trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. Is health worth asking for? Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your feelings, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

MRS. M. SUMMERS, Box 309 Windsor, Ontario

thing that flies carry about. They swarm about open sewers, drains, and outhouses, which receive millions of disease germs which have passed through the bodies of sick people. Flies in this way pick up and carry on their bodies, heads and legs (which are covered with fine hairs—just suited for catching and holding this sort of thing) the germs of typhoid fever, summer diarrhoea of children, tuberculosis, and several other diseases. Dr. L. O. Howard, Chief Entoomologist of the United States Department of Agriculture calls the common house fly the Typhoid Fly, because so many cases of typhoid fever have been caused by its carrying the germs from one sick person to another. These germs are so small that you cannot see them with a microscope, but the fly that is eating from the same plate with you may be carrying a million of them.

Flies kill more people than wild beasts and poisonous snakes. Many of these beasts and snakes never get a chance to kill any human being; but any one of the millions of flies found in most of our homes and cities has a chance if it comes into the house carrying typhoid germs, of killing a whole family.

Flies Breed Quickly

Most house flies in cities are hatched from eggs which have been laid in horse manure. Some breed in other forms of filth, such as garbage cans, heaps of refuse in back yards, etc. The fly lays 120 or more eggs at a time. These, if they are not disturbed, become maggots in about 12 hours. In from 5 to 8 days more, the maggots enter the pupa stage, as caterpillars do, and after from 5 to 7 days come out of the earth or manure in which they have buried themselves in the form of flies, ready in a few days to become the fathers and mothers of large families. They breed so rapidly that in one summer the children and grand children of one pair of flies may amount to thousands of millions. And remember that the germs they carry multiply much faster than the flies.

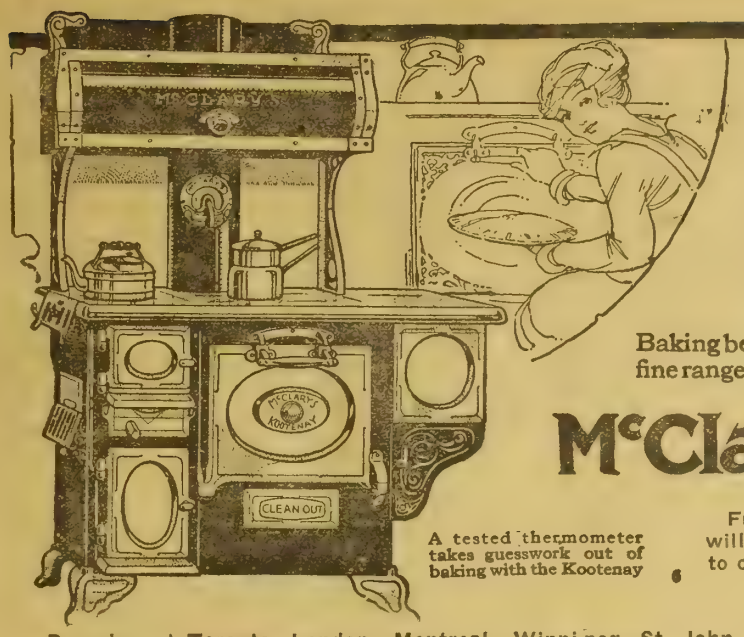
To prevent flies from breeding, screen the stable if possible. Remove the manure at least twice a week. If flies being to breed in stored manure they may be killed by thoroughly spraying it with kerosene or Paris Green and then pouring enough water to thoroughly wash the oil or poison in. The objection to the use of kerosene is that it ruins the manure for fertilizing purposes.

It is well to abolish old-fashioned outhouses where possible. Where this cannot be done a liberal amount of lime should be used, aplied in small amounts daily. Chloride of lime is better than slaked lime, but slaked lime is better than none at all. Garbage barrels should be thoroughly cleaned after emptying, and the contents should be thoroughly cleaned after emptying, and the contents should be sprinkled with crude oil. And finally, keep flies out of the house by screening the doors and windows.

Beware The Fly

It is now an acecpted fact that the fly is the cause of spreading many diseases; we would therefore call our readers' attention to the following rules:

1. Keep the flies away from the sick, especially those with contagious diseases. Kill every fly that strays into the sick room. His body is covered with disease germs..
2. Do not allow decaying matter of any sort to accumulate on or near your premises.
3. All refuse which tends in any way to fermentation, such as bedding straw, paper, waste and vegetable matter, should be disposed of or covered with lime or kerosene oil.
4. Screen all food.
5. Keep all receptacles for garbage carefully covered and the cans cleaned or sprinkled with oil or lime.
6. Keep all stable manure in vault or pit, screened or sprinkled with lime, oil or other cheap preparation.
7. Cover food after a meal; burn or bury all table refuse.
8. Screen all ofod exposed for sale.
9. Scren all windows and doors, especially the kitchen and dining room.
10. Burn pyrethrum powder in the house to kiil the flies.
11. If no dirt exists there are no flies.



THINK of the time and trouble you can save with this dependable range.

No black-leading. The cooking-top is burnished brighter than steel. Grates—the modern duplex type—clean the ashes out at a single turn. Oven walls nickeled steel—easily cleaned.

Baking becomes a real pleasure when you have this fine range to work with. Call and see the Kootenay.

McClary's

FRUITS TO SERVE WITH MEATS AND FOWLS

Sometimes when we wish to serve a partticularly nice dinner and have everything up to the standard, we are at a loss to know just what fruits should be served with certain meats and fowls. Following is a list that should prove of great help to any desiring this information. It might be a agood idea to cut it out and file it for reference:

Ham. — Apple jelly or mustard pickles.

Roast Beef.—Yorkshire pudding and tomato jelly.

Roast Pork.—Apple sauce.

Stewed Mutton.—Salad and creamed onions as the vegetable.

Turkey.—Cranberry sauce or currant jelly.

Chicken (roast).—With chestnut stuffing serve chestnut sauce.

Chicken (boiled).—Oyster, celery, lemon or caper sauce.

Chicken (broiled).—Serve with tartar sauce.

Chicken (fried).—Tomato sauce.

Goose—Garnish with watercress, serve apple sauce or fried app'es.

Ducks.—Olive sauce and green peas.

Grouse.—Bread sauce.

Pigeons.—Spinach and toast.

Venison.—Currant jelly.

HEAVY PASSENGER TRAVEL ON C. N. R. LINES

Passenger travel is remarkably on sections of Canadian National Railway Lines, and particularly so in the Eastern section where trains between St. John, Halifax, Sydney and Montreal are every day filled to capacity. The popularity of the Maritime Express and Ocean Limited is amply demonstrated by the many applications for sleeping car reservations on these well equipped through trains.

Requests for space are so numerous that extra cars are being caried and often trains run in two sections. With the rush of travel from troop steamers arriving at Halifax and Quebec this means considerable of a strain on the railway for equipment.

Passenger business which has been very brisk all summer, is likeyl to continue through the fall.

MOTION PICTURES OF MATAPEDIA VALLEY

While on the C. N. R. special train from Halifax to Quebec recently, carrying newspaper men and moving picture operators, who were following the Prince of Wales on his tour, some of the motion picture men secured views of the Matapedia Valley. They mounted the deck of the locomotive and operated their cameras while the train sped through the Morrisey Rock Tunnel and across the Restigouche Bridge. At a point beyond Matapedia station the train was stopped and several group pictures were filmed.

These pictures will be shown in connection with the news films of the Prince's tour.

BROILERS

Under ordinary conditions the most profitable time to market cockerels of the light weight varieties is unquestionably at the broiler age.

All surplus Leghorns and cockerels of similar breeds sould be disposed of at this stage, as the quality of the flesh rapidly lowers with age and they are consequently not in demand as roasters.

The most desirable weight for broilers is from a pound and a half to two pounds each and the quicker the chick can be forced to these weights the better the quality of the broiler.

In growing broilers the chicks may be fed and handled in the usual way until they reach the age of about six to eight weeks. The cockerels should then be separated from the general flock, kept in confined quarters and forced with ground grains, mash and milk, just an occasional feed of wheat or cracked corn being supplied to stimulate the appetite.

Milk is essential if the highest quality is to be secured and when fed sour it acts as a stimulant and keeps the appetite keen.

A mixture of sifted ground oats and corn, corn, oats and barley, or buckwheat, oats and barley, makes a good ration. This should be mixed to a rather thin batter with sour milk and fed at leas three times a day, all the chicks will clean up.

They should have at least two weeks feeding of this kind before being marketed.

When ready they should be starved ofr at least twelve hours, bled and neatly dresesd, care being taken to avoid tearing the skin when plucking, as they are very tender and consequently easily torn at this age.

Those who are not experts at dressing or who live at a distance from market can make arangements to ship to a dealer who will dress and deliver at so much per pair. This is usually a better plan than shipping dressed in hot weather as the danger from spoiling under this method is great.

For the week of July 8th broilers were quoted in a wholesale way at 45 to 50 cents per pound in Montreal; 40 to 45 at Toronto and Vancouver. Where shipping to clubs and retailers considerably higher prices can be realized.—George Robertson, Assistont Poultry Husbandman, Central Experimental aFrm, Ottawa, Ont.

A MESSAGE TO WOMEN!!

LET a woman ease your suffering. I want you to write, and let me tell you of my simple method of home treatment, send you ten days' free trial, postpaid, and put you in touch with women in Canada who will gladly tell what my method has done for them.

If you are troubled with weak, tired feelings, headache, backache, bearing down sensations, bladder weakness, constipation, catarrhal conditions, pain in the sides, regularly or irregularly, bloating, sense of falling or misplacement of internal organs, nervousness, desire to cry, palpitation, hot flashes, dark rings under the eyes, or a loss of interest in life, write to me today for free trial treatment.

Mrs. M. Summers, Box 309 Windsor, Ont.

FORESTALLING BATTERY IGNITION TROUBLES

Attend to the Sparking Devices and Avoid Involuntary Stops

Different battery ignition systems vary so greatly in detail that the suggestions here given can be of a general character only and the instruction book relating to the particular system in question should always be folloed. Don't fail to lubricate the bearings and gears of the timber shaft, by means of the grease cup usually provided. See that the make-and-break mechanism works perfectly freely and that no dirt or oil is present to make it act sluggishly. If the contact-points do not come together over their full surface, it is usualy advisable to fit them so they do, by placing a thin jewelers file between them, pressing them together, and withdrawing the file, repeating this operation until a full contait is secured. A piece of very fine sandpaper can be used in the same manner as the file (reversing it so as to act upon each point,) if only a little treatment is needed or if the metal is very hard. If the points are too inaccessible to be treated in this way they can usually be removed and trued up separately on a small oil stone. The points of some breaker mechanisms are not intended to be "doctored," but to run as long as they will and then be replaced and it is well to have the replacement parts on hand and to know how to put them in readily. Any spring parts of the timer, that are likely to break, should be kept in duplicate. The contact points of all timers should be kept adjusted for the recommended distance of separation, a thickness guage being furnished with each outfit. The correct gap is usually 1-32 inch or less and much variation from this will change the timing or cause missing. Be sure there is no dust in the distributor housing, as the high tension current may short circuit upon it. Never use oil about the distributor, but a very little vaseline rubbed over the path of the rotatnig contact and then mostly wiped off, is sometimes recommended. The automatic advance mechanism, if present, requires lubrication. If the equipment includes an ignition switch, designed to open automatically and thus protect the battery from accident discharge, its efficacy should be demonstrated once in a great while. Try, for firmness, all connections of every wire and cable including those at the timber distributor, the ignition switch, the coil, the grounding point and at the connection board, where the ignition circuit obtains its current. If there are un-armored primary wires see that they are properly fastened in place and not oil soaked or being broken by repeated bending. Keep dust and oil wiped from the spark-plug wires and the distributing casing.

CLAIMS HIS FORD IS WORN OUT

E. G. writes: Please tell me what to do with a worn out Ford.

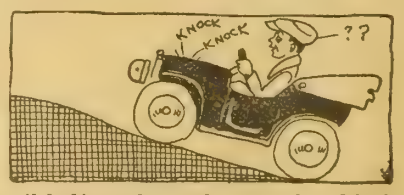
Answer: We think perhaps you may be joking, as there is a general opinion that Fords never wear out, but continue to "ramble right along" indefinitely. However, we are going to take your inquiry seriously. We cuggest that you obtain an estimate from a Ford agency as to how much it will cost to put this car in good order and, if this amount is very considerably less than the selling price of used cars of this model, we should advise you to have the work done and sell or keep the car. On the other hand, if repairs will cost nearly

as much as the car will sell for, we advise wou to dispose of it to some "auto wrecker" for what you can get. Some people retain the body for the childrei to play in or place it on the lawn and grow flowers in it, not wishing to give up entirely an old and faithful friend.

IS THIS A COMPRESSION KNOCK?

F. W. writes I have a four-cylinder 1919 ——— which knocks badly on hills, but when I pull up the rod that chokes the carbuetor air, the knocking stops. Can you tell me if this is a "gas" or a "compression" knock?

Answer Assuming that the cylinders are clear of carbon, that you are sure that the spark is not so far advanced as to cause the sound complained of and that the mixture, at full throttle and low speed is not so lean as to result in a low pulling power, we fancy that this is a compression knock. If you will obtain enough real, high-test gasoline to partly fill the tank and



wil ladjust the carburetor for this fuel and run a while upon it you can soon tell. Should knocking cease it may be safely assumed that the compression rate is too high for the fuel regularly used, but if it still continues, the cause must be sought elsewhere. You may well try this experiment, before reducing the compression rate. When you choke the air, you make the mixture so rich that it burns slowly and at a temperature too low to produce the detonating reactions in the combustion, which are the supposed cause of the compresion knock, when actual preignition does not take place.

CALLING IN THE SPECIALIST

When something breaks or wears out it is usually a perfectly straightforward proposition to obtain a new one and have it put in, but when the engine develops an elusive "skip," when it suddenly or gradually loses power in an obscure way, when the radiator develops an inexplicable tendency to boil, or when the battery, for no apparent cause refuses to keep charged, the situation is different. Obviously there is a cause (or causes) for each such baffling trouble, but to determine what it is, may often be beyond the diagnostic powers of the motorist concerned and expert advice is sought. No one can estimate the huge sums of money, which car owners have squandered for labor and material, consumed in following out treatments based upon false diagnosis, and the suggestions here given are intended to protect motorists from losses of this kind: When trouble due to an obscure cause develops, consult the best qualified expert available, obtain his opinion and pay him his fee, but do not act upon his advice at once, but on the contrary, obtain the opinion of another qualified man. If these two "doctors disagree," try a third expert and keep on with this informal "consultation," until you obtain the same diagnosis and recommended treatment from more than one. It is good economy to pay for all this advice rather than to obtain the opinion of one man free and allow him to do the work suggested as necessary (but perhaps not requfred at all) at his own shop. Give the experts you consult plenty of time to look your car over and to think over the "symptoms." Avoid the expert who has any panacea to sell, for he may be unconsciously biased. If he is a carburetor agent, he will most likely prescribe a "new one" when the trouble is really in the breaker-box. Should he happen to be a piston ring merchant, he may ,in perfect good faith, recommend a full set of this "jewelry" when, in reality, new expensive valve springs are needed. If the recommended treatment is of an expensive kind, don't begin upon it until two or three experts agree that it is what is required. The advice of a felow motorist or a neighbor's chauffer, who has driven cars before the average "expert" reached the voting age, may often be worth as much as that of a professional. Certainly it is worth something.

CAR "LAYS DOWN" ON UP GRADES

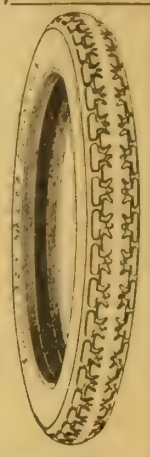
A writes I have a 1918 car which "falls down" on speed, when going up the least incline. The engine is likely to stall whenever the car is stopped or slowed down. Have had valves ground and timed. What is the nature of this trouble?

Answer: Assuming that your ignition is all right this looks like a case

of too lean mixture. which is almost sure to result in very low power and uncertain engine operation at low speed. You better have the carburetor re-adjusted to feed a little more gasoline in proportion to air. If this does not improve conditions please write us again. We suggest that you have no more work done upon the car until you have tried the above suggestion for such operations as grinding valves on a new car like this. under conditions such as you describe are useful only to the ones who do the grinding.

Maltese Cross Tires

MALTESE CROSS TIRES give that extra wear and riding comfort that is appreciated by discriminating motorists. The sense of surety experienced by motorists with MALTESE CROSS TIRE EQUIPMENT can be yours, too. If that old bugaboo, "Will my tires get me back without trouble?" worries you while touring, equip your car with "The Tires That Give Satisfaction" and enjoy yourself. Tire troubles seem extra shy of the



Non-Skid Tread

Maltese Cross Brand

Ribbed Tread

Notice the number of cars that are to-day equipped with MALTESE CROSS TIRES. Motorists do not change equipment without good reason. Can you be satisfied with ordinary tires when the super-wearing qualities of MALTESE CROSS TIRES are so apparent?

ENGINE MISSES FROM CARBONIZED PLUGS

D. W. P. asks: Why do the two front spark-plugs of my Ford continually fill up with carbon so that the engine misses to such an extent that I can get but 10 to 12 miles per gallon? Would it be of any use to try rings of another make? Ignition seems good, but would some other than the standard Ford type give better results?

Answer: If the plugs carbonize from oil ,the piston rings are still at fault. Properly fitting Ford rings

ought to make the pistons tight, but posibly patent rings might prove better. If the carbon upon the plugs is gasoline soot, it denotes that these two cylinders receive too rich a mixture, which is most likely because the intake manifold runs too cold to vaporize the fuel properly. A heated manifold and a lcoser adjustment of the carburetor might correct this. A high-tension magneto or a modern battery system would improve your ignition results. If gas rapidly leaks out of these cylinders, when they are cranked through their compression strokes, it is evident that the rings still fit so imperfectly that an escape of oil past them is to be expected.

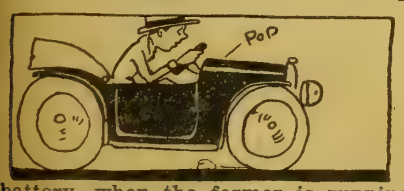
THE EVILS OF VIOLENT OPERATION

Attenton cannot be too often called to the destructive effects produced alike by starting and by stopping a car suddenly and inconsiderately. Too often, the starting operation is performed about like this: The clutch is pushed out and the gears are instantly jammed into mesh, with a clash, before they have stopped spinning. The engine is speeded unti lit buzzes and the clutch pedal is allowed to snap back at almost its own speed. The passengers necks are nearly dislocated, every transmission part receives a life-shortening jolt and the tires slip on the road, tearing down their tread rubber or loosening it and stressing the fabric more than would miles of legitimate esrvice. When approaching the stopping point speed is not slackened until within a short distance of it, when the brakes are jammed on with full power, the wheels lock and the car slides up to its destination, writing a record of the abuse in a flat spot on each rear tire, where the tread has been "scuffed" off. This is admittedly an extreme description, but nearly as bad car abuse can be witnessed any day on any largely traveled street and it is given as an example of "how not to do it." Jusa reverse everything and it becomes a recipe for careful and considerate operation.

GENERATOR FUSE BLOWS

D. W. P. asks: What makes the fuse, used in connectiono with the generator of my car, burn out every once in a whie? It has done it several times lately just when I shut down the engine.

Answer: Most likely this is caused by the occasional failure of the relap



battery, when the former is running so slowly that it does not generate voltage equal to that of the latter. Under these condition a very large current flows in the wrong direction, i. e., from the battery into the generator and the fuse melts out in order to protect the generator and battery from damage. Not knowing what electric system you have, we cannot say certainly, but it is possible that the relay spring-tension is weak or that the contacts stick together. You better have an electric service man look for this trouble and remedy it at once.

UNDERCHARGED BATTERY

J. L. P. writes: Lately the lights on my car have been somewhat dim while the engine is stopped and I have noticed that they suddenly brighten when I speed up the engine a little. Does this mean that anything is wrong?

Answer: It indicates to us that your battery is undercharged. The sudden increase in brightness of your lights of which you speak, is due to the fact that the generator voltage is considerably higher than that of the battery and when the generator is electrically connected to the system (as it is whenever the engine speed rises to a certain point) the lights burn at the higher generator voltage, with increased briliancy. You should take measures to keep your battery fully charged, first making sure that it is in good condition and free from internal short-circuits and that there are no leaks in the wiring. It may be that your generator should be adjusted to furnish a larger charging current. This and any other adjustments needed can be made at any electrical service station.

FUEL FEED INQUIRY

L. E. W. writes: I have a car that has its gasoline tank under the front seat instead of at the rear, and sometimes, when there is only a little gasoline in it, there is no flow to the carburetor, on steep hills. What I wish to know is whether a vacuum tank system can be applied in this case.

Answer: Yes, the vacuum feed system can be made to operate under these conditions, as well as it can in connected with a rear mounted tank.

DEMOUNTABLE RIMS OR SPARE WHEEL

T. W. F. writes: I am thinking of improving the tire equipment of my Ford, which now carries the standard outfit. Do you recommend the demountable rim or the spare wheel equipment?

Answer: The 30x3½ inch equipment on all four wheels is what you require. There is some difference of opinion as to whether the demountable rim or the spare wheel is the better, but the former should be rather lighter and perhaps somewhat more secure mechanically and personally we rather prefer it. However, in case of a wheel breakage, the latter possesses an obvious advantage.

RUBBER PRESERVATIVE PAINT

T. W. F. asks: Does the commercially advertised tire paint cause any injury to tires.?

Answer: No, quite the reverse. A good preservative compound of this

kind acts to fill small cuts and cracks in the tread rubber and to delay their becoming larger and finally of sufficient size to admit water and dirt, that will tend to loosen the tread and cause sand blisters. At least, these claims are made for these preparations and they appear reasonable.

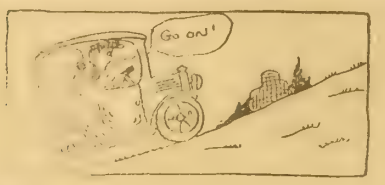
HILLS TOO STEEP FOR GRAVITY FUEL FEED

A. P. J. writes: My Ford Sedan will not climb some of the steepest hills in this city. After its stalling on one of these, I disconnected the gasoline pipe at the carburetor and found that I had to lower the detached end three inches below its point of connection before gasoline would flow from it, although there were nearly five gallons of fuel in the tank. How can I remove the difficulty?

Answer: The fuel flow on these closed cars fails, on sharp up grades, with a larger amount of gasoline in the tank, than does that on the open models, because the tank of the closed

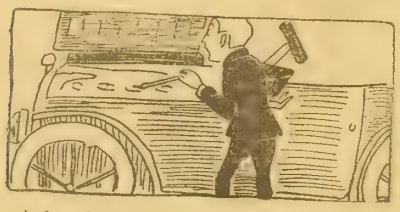


models is of a somewhat flat form, while that of the open cars is cylindrical. Installing a vacuum fuel feed system is the remedy for your trouble and we are quite sure that some of the manufacturers of these devices can furnish you with such apparatus, with special fittings for mounting the tank. Some users have attached to Ford fuel tanks, apparatus for creating a temporary pressure feed, consisting of a hand-operated air pump, delivering into the top of the tank, a gasket under the filler cap to make it air tight and means for venting the tank pressure is not being used. We recommend the vacuum feed arrangement rather than this.

IDENTIFICATION OF MISFIRING CLYINDER

T. W. F. asks: How can I tell which cylinder of a Ford engine is missing explosions?

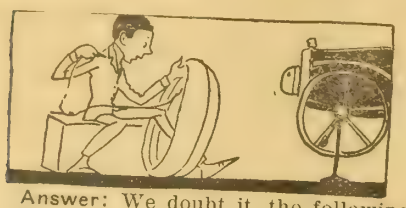
Answer: Set the engine running at a moderate speed and take a screwdriver with a wooden handle and touch its blade simultaneously to the metal top of a spark-plug and the cylinder. This will stop that plug from sparking. Do this to each plug in turn and if, when it is tried on a



certain plug, the engine does not slow down, this plug has not been firing properly. Another method is as follows: Remove the coil-box cover and stop each vibrator successively from operating, by holding it down with the finger. A vibrator, which can be stopped without causing the engine to lose speed, is furnishing current to a cylinder which is missing explosions.

RENOVATED CASINGS

M. S. asks: Is it profitable to have two old casings sewed together to make a new tire? There are parties that claim great things for this process.



Answer: We doubt it, the following being some of the objections which we have heard raised against the process: The result is a very thick, stiff shoe and one with too thick a wall, can hardly bend adequately to absorb road irregularities without fabric breakage, which shortly leads to a blowout. Such a thick, stiff casing makes a car ride hard, heats to such an extent as to destroy the tube prematurely and absorbs excessive power. Being built up of fabric, presumably already considerably deteriorated, it has less strength than might be supposed. As this process is sometimes carried out, the outside fabric is not carried to the bead and side wall blowouts—very common with all casings—are likely to occur very early.

Champion Tractor Plugs Insure Tractor Efficiency

The tractor is one of the most severe of all service tests to which Spark Plugs are subjected.

Its low speed and continuous heavy load, whether on draw-bar or belt, develops a terrific heat with tremendous shock strain and vibration.

Its efficiency depends on the ability of its spark plugs to withstand such gruelling punishment.

Champion "Tractor" for Fordson A 14, ½ inch. Price $1.00

Champion

Dependable Spark Plugs

have a "built in" dependability, and have long since proved their ability to render satisfactory service under any condition in every type of tractor or farm engine—just as they have in the more than two hundred makes of motors in which they are regular factory equipment.

Sold wherever Motor Supplies are sold.

"Heavy Stone" for Tractors and heavy service Motors.
B 13, ½ in.
B 43, ⅞-18.
B 53, ⅞ long.
Price $1.25.
Ball terminal furnished when specified; otherwise regular knurl nut.

Champion Spark Plug Co. of Canada Limited

Windsor, Ontario.

A NEW PARSNIP DISEASE

Parsnips stored in cellars at the Manitoba Agricultural College are found to be badly infected by a disease which seems to be what is known in England as the parsnip canker or rust, writes Prof. F. W. Brodrick, of the Manitoba Agricultural College.

This disease develops after the storage as a black, warty-like growth, which sets up a decay that destroys the whole root. Experiments carried out in England indicate that the disease is not carried by transference of soil, or by portions of affected roots. A number of cultural remedies were suggested which might apply to Manitoba conditions:—

1. Avoid sowing parsnips on too rich a soil. Too rapid growth tends to develop cracking.

2. Apply lime to the soil, which has a beneficial effect in developing better quality in parsnips and in retarding decay. Lime may be applied at the rate of two hundred pounds per acre.

3. A dressing of coarse salt was found effective by some growers. The application of salt tended to liberate potash in the soil, which stimulated the growth of tissues that were most resistant to the disease.

4. Rotation of crops, or not growing two successive crops on the same land, would retard to a certain extent the development of the disease.

The disease itsel fis evidently largely induced by unfavorable growth conditions in the parsnip which cause rupturing of the external tissues. The methods of control are to so regulate the soil conditions as to prevent a very rapid and unfavorable growth.

Weeds and grass in the garden use up plant food and have a tendency to make vegetables grow weak, even if there is plenty of moisture in the ground.

Proper planting of trees in the yard and orchard pays not only in things of the finer sense of beauty and pleasure, but has a very practical side also, for the whole barn yard and orchard add very materially to the value of any farm or home.

MARKETS.

THE PROVISION MARKET

Montreal, Sept. 6—A weaker feeling has developed in the market for live hogs since Monday and prices in the Toronto market have declined 50c per 100 lbs. with latest sales reported at $21 per 100 lbs. weighed off cars, and at $20.75 fed and watered. In sympathy with this and the lower prices ruling in the American markets, coupled with the increased offerings here today the local market was also weaker and prices dropped $1 per 100 lbs. The demand from packers at the lower level was good and an active trade was done with sales of selected lots at $20.50 to $21 per 100 lbs. weighed off cars. O naccount of the above the market for dressed hogs displayed weakness and prices were reduced 50c per 100 lbs. with sales of abattoir fresh-killed stock in a jobbing way at $31 to $31.50 per 100 lbs.

There was no actual change in prices announced for smoked or cured meats today, but the indications are that there will be a readjustment of values in the near future owing to the weakness in hogs and the fact that prices are now considerably lower than the recent high level. The demand continues good for supplies for domestic consumption and trade in a jobbing way is reported fairly active with sales of 8 to 10 lbs. hams at 46c per lb., 12 to 15 lbs. at 44c, and heavy weights at 40c, while breakfast bacon is selling at 50c, special brands at 52c to 54c, and Windsor boneless bacon at 56c. A small trade is passing in barreled pork in a jobbing way with sales of short cut and fat back grades at $60 per barrel.

The condition of the market for lard was unchanged, prices being steady under a good demand for supplies and sales of Canadian pure leaf grades were made at 40c to 40½c per lb. in 1 lb. blocks, and at $7.60 per 20 lb. wood pails, while American compound lard sold at $6.50 per 20 lb. wood pails, and shortening at $6.30 per 20 lb. wood pails.

The receipts of provisions today were 25 barrels pork 2,885 packages lard, 521 boxes hams and bacon, and 687 packages tinned meats.

Chicago, September 3.—Provisions, like corn, were depressed by current statements from influential sources that foodstuffs were to decline. Prices closed unchanged to a loss of $1.

Future quotations were:

	Open	High	Low	Close
Mess pork, per bbl.—				
Sept.	$41.50	$42.00	$41.25	$42.00
Oct.	37.00	37.30	35.70	37.25
Lard, per 100 lbs.—				
Sept.	28.00	28.00	27.10	27.10
Oct.	27.40	27.40	26.70	26.70
Short ribs, per 100 lbs.—				
Sept.	22.00	22.00	21.55	21.60
Oct.	22.00	22.00	21.37	21.47

Cash prices closed: Pork, nominal. Lard, $27.10. Ribs, $21.25 to $22.25.

DAIRY PRODUCE TRADE

Monreal, Sept. 6.—The receipts of butter today were 348 packages, as against 330 for the same day last week, and 923 for the same date a year aago. It was reported today the lot of pasteurized creamery offered yesterday at the auction sale was sold at 54½c per lb., and the lot of finest at 54c. The market today in a wholesale way was very quiet with nothing of interest to note, the demand from all sources being slow.

We note wholesale jobbing prices as follows:

Pasteurized creamery 51½c to 55c
Finest creamery .....54¼c to 54½c
Fine creamery .....53½c to 54¾c
Finest dairy .....49c to 50c

The recipts of cheese today were 16,509 boxes, as compared with 9,650 for the sam eday last week, and 14,060 for the corresponding date a year ago. A scarcity of colored cheese for the home trade has developed during the past few days and the same has been selling at a premium of from ¼c to 1c per lb. over white, but apart from this there is nothing of importance in the situation to note. The Dairy and Cold Storage Branch of the Department of Agriculture in their weekly letter say: In France butter and cheese are both scarce as compared with pre-war times, and higher in price. First class retails at from 75c to $1.15 per lb. Cheese varies greatly in price acocrding to the kind, retailers charging from 75c to $1 per lb.

The Canadian Cheese Export Committee will pay the following prices for all cheese delivered to warehouse Montreal:

No. 1 grade, per lb.....25c
No. 2 grade, per lb.....24¼c
No. 3 grade, per lb.....24c

New York, Sept. 5.—Butter, firm. Receipts 8,610 tubs. Creamery, higher than extras, 58½c to 59c; creamery, extras, 92 score, 58c; firsts, 54c to 58½c; packing stock, current make, No. 2, 46c. Cheese firm. Receipts 10,578 boxes. State, whole milk, flats, current make, specials, 30¾c to 31¼c; do. average run, 30c to 30¼c; State, whole milk, twins, current makes, specials 30½c to 31c; do. average run, 29½c to 30c.

THE CATTLE MARKET

Montreal, Sept. 6.—At the Canadian Pacific Live Stock Market the offerings today amounted to 400 cattle, 800 sheep and lambs, 525 hogs and 200 calves. There continues to be a steady demand for supplies from outside buyers and a fair volume of business has been done in this respect this week, which has relieved the market of its surplus offerings. Sales of two cars of cattle were made for shipment to Buffalo, one car of cattle and one of sheep and calves to New York, five cars to Boston, and in addition to this three cars of cattle were for shipment to Lancester, and one car of hogs mor Toronto.

There was a fairly good demand for cattle today and the market was more active than usual in the middle of the week. The supply was not large but it was ample to meet all immediate requirements. Sales of the best steers available were made at $12.50 per 100 lbs. while lighter grades brought from $10.50 to $11.50, medium to fair from $9 to $10, and common $7 to $8. The top price paid for cows was $9 and the lower grades sold from that down to $7, with canners at $4.50 to $5.50. The quality of the bulls offered consisted chiefly of common stock which sold at from $5.50 to $7.

The feature of the market for small meats was the weakness in hogs and prices scored a decline of $1 per 100 lbs. as compared with those paid on Monday, which was attributed to the increased offerings and in sympathy with the lower prices ruling at other Canadian markets. The demand at the reduction was fairly good and sales of selectel lots were made at $20.50 to $21 per 100 lbs. weighed off cars, with a sut of $2 per 100 lbs, for rough mixed lots, $5 for sows, and $7 for stags.

A steadier feeling prevailed in the market for sheep and lambs on account of the increased demand from outside buyers for supplies for shipment to the United States and an active trade was done with sales of Ontraio stock at $13.50 to $14, and Quebec at $12 to $13, while sheep sold at $6 to $8 per 100 lbs. The tone of the market for milk-fed calves was stronger and prices ruled 50c per 100 lbs. higher on account of the small offerings and the good enquiry for the same with sales of choice at $15 to $16, and good lots at $12.50 to $14.50 per 100 lbs. The market for grass-fed stock was steady with supplies ample for all requirements and sales were made at $7 to $9 per 100 lbs. as to quality.

MILLFEED AND ROLLED OATS

The market for millfeed was without any new feature to note, prices for all lines being unchanged on account of the continued limited supplies available and the good demand for the same. Car lots of bran are quoted at $45, and shorts at $55 per ton, including bags, ex-track, and small quantities of corn feed in mixed car lots sold at $80 to $82, pure barley meal at $70 to $71, mixed grain moullie at $70 to $72, and dairy feed at $48 to $50 per ton, including bags, delivered to the trade. There was no change in the condition of the market for rolled oats, the demand being still somewhat limited with millers in some cases quoting broken lots of standard grades at $4.80 to $4.90, and others at $5 to $5.25 per bag of 90 lbs. delivered. Golden cornmeal is selling at $5.75 per bag.

THE BALED HAY MARKET

There was no important change in the condition of the market for baled hay, business being quiet owing to the fact that buyers in most cases are not disposed to operate to any extent at present prices ruling, and the demand is chiefly for lots to meet immediate wants, as the indications are that prices will reach a lower level in the near future. Sales of car lots of good timothy hay were made at $20 to $21 per ton, ex-track.

THE NUMBER OF TREES IN AN ACRE

I intend to lay out an acre of land for an apple orchard. How many trees will plant an acre? M. K.

You do not state how wide you intend to plant the trees and rows apart, but the following rule will give you number of trees at varying distances.

To determine the number of trees per acre for any given distance multiply the distance between the trees in the row by the width of the row. Take that number and divide 43,560 by it. The resulting figures will give the number of trees per acre.

The number of trees to set per acre:

16x16 feet—170 trees.
18x18 feet—134 trees.
20x20 feet—108 trees.
20x30 feet— 72 trees.
24x24 feet— 75 trees.
25x25 feet— 69 trees.
30x30 feet— 49 trees.
32x32 feet— 42 trees.
36x36 feet— 33 trees.
40x40 feet— 27 trees.

BARN VENTILATION

(Contnued on page 856)

Another type of protection was devised, which is more satisfactory. It was found to be of considerable value in preventing, at least partially, an increased volume of air entering the inlet when the wind was blowing strongly against that side of the barn.

It has been found that it is better not to have louvers in the cupolas, but rather to allow the wind to blow straight through to avoid back drafts. Cupolas should not be made too large. Director J. H. Grisdale, of the Dominion Experimental Farms, strongly favors the open type cupola; it is used on all new Experimental Farm barns. There is a tendency in recent barn construction to discard cupolas entirely and to use galvanized iron cowls instead, both for barn ventilation and for ventilatioin of the hay loft. There are a number of good cowls on the market at the present time. The claim for them is that they will not back draft.

WORLD OF LIFE THAT EXISTS IN THE SOIL ON EVERY FARM

So much is still to be known in the world of nature that the Ottawa Farm Journal believes it is safe to say that most people are just beginning to realize how little they do know. To the farmer truly the increase of knowledge in things pertaining to plant growth is an increase of power. It had been known for some years that soils which had been subjected to a process of sterilization by heating or exposure to antiseptics gained thereby a marked increase in the power of producing crops. To understand the subject it is necessary first to obtain a general idea of what is going on in the soil. It is not so very long ago when scientists and farmers regarded the soil they examined and tilled as dead matter and believed that the activity within it was only chemical. But within the past few years opinions have changed. Decomposition, which was considered as a purely physical process, is now known to result from minute vegetative organisms or bacteria that render the soil suitable for the higher plants. Recent investigation at the Rothamstead experimental station, England, into the causes of land sickness revealed a new factor in the life of the soil, and one which promises to be of extreme interest and perhaps of practical importance to the farming industry.

These micro organisms exist in numbers so vast that, stated in figures, they have hardly a meaning. Thus, it is computed that in one gramme of ordinary loamy soil the number of bacteria is usually about 4,860,000, and may be much more, while in soil composed mainly of leaf mould under beech or oak trees the number may rise to 30, 40 or even 50 millions. These are tremendous numbers, but it must be remembered that bacteria are very small. The largest of them are far below the level of visibility, and the smallest elude the best microscopes, and are only to be inferred from their actions and products. In the language of the man of science, they are so very small that the "saturation point" would only be reached when there were 600,000,000 in one cubic centimetre of soil.

Fertilizing Microbes

They have various functions as soil makers. Some are engaged breaking up the purely mineral matter in the soil, and in the rock and sub-soil below it. Others, a numerous company, are engaged decomposing dead animal and vegetable matter in the soil. Others, again, and from the point of view of the agriculturist they are the most important of all, are engaged in diverse ways in fixing atmospheric nitrogen, and in reducing the nitrogen of ammonia to a state in which it becomes available for plant life. The peculiar importance of these is due to the fact that no element in the fertility of soils is more quickly exhausted by plants than nitrogen, while even when artificially supplied it is generally in a form which requires the labor of bacteria to bring it to the right state for use. Thus the fertility of soil is almost absolutely determined by the abundance of nitrogen fixing bacteria operating within it. If they are scarce the soil is poor; if they are abundant the soil is rich.

But for a long time one paradoxical fact seemed to disturb all these results, and write a big mark of interrogation against them. It was found that when the soil was sterilized either by heating or by the employment of a disinfectant, instead of losing fertility, as would be expected, it became markedly more fertile than unsterilized soil. This was first noticed in connection with attempts to kill insect pests by means of carbon disulphide. The poison killed the insects, and it killed the bacteria as well; and as fertility goes with bacteria a certain degree of infertility should have been the result. The contrary was the truth. Systematic work, however, soon showed that, while antiseptic treatment destroys a large proportion of the bacteria of the soil the investigator had only to await for a few days to find them more abundant in sterilized soil than in soil which had been untreated. In one of the Rothamstead soils, for example, every gramme contained at the outset 7,000,000 organisms, a number which, after heating, fell to 400, and within a short time rose again to such a degree as to make counting impossible. Treated with toluene, which acts less drastically than heat, the 7,000,000 were reduced to 2,600,000; but in nine days the number rose again to 40,000,000 or far in excess of the number ever found naturally in this kind of soil. It thus became an interesting and important matter to account for so marked an increase of life in soil following upon treatment which had for its purpose the destruction of life.

Bacteria Eaters

The explanation introduces us to the struggle for existence at low levels. A single bacillus, multiplying by subdivision, is capable of producing millions of its kind in 24 hours, but as the numbers in any particular soil remain fairly constant it follows that some factor is always at work restraining their increase. In the search for such a factor it was found that, in addition to the bacteria, there abound in the soil various animal organisms of the protozoa family, exceedingly minute (but still larger than the bacteria), which exist by preying upon the bacteria, and therefore keep them in check. In short these protozoan pigmies of the animal world act in the soil as the phagocytes act in the blood, and wage a constant warfare on the pigmies of the vegetable world. The warfare waged by the phagocytes is beneficent, and animal life would soon cease but for their activities. The warfare waged by the phagocytes of the soil maintains a sort of equilibrium between themselves and the bacteria, and though they may serve some useful purpose they undoubtedly put a limit to the useful work of the bacteria in fertilizing the soil by add-

ing to its supplies of fixed nitrogen.

With this discovery the solution of the mystery of the fertility of sterilized soil became easy. In heated soil the protozoa are completely destoryed, while numbers of the bacteria or their spores survive the ordeal. When, therefore, these survivors begin to multiply again on the cooling of the soil or the evaporation of the sterilizing agent they go ahead without check. They find themselves in an environment from which their natural enemies have been removed, and their wonderful powers of multiplication are exerted to the full. When the sterilization is complete enough to kill all the animal life in the soil the development of the bacteria goes so far that, aas has been said, all attempts to count them, even approximately, became impossible.

That this discovery will lead to important economic results there is every reason to believe, and they will come when a not too costly method has been discovered for effecting the suppression of the injurious protozoa in the open field.

PENNY CRESS OR STINKWEED

This plant, which is also known as Frenchweed, spreads by seeds only, being either an annual or winter annual. In the former case the seeds lie dormant in the ground during the winter and germinate in the spring; in the latter case the seeds germinate during the late summer and pass the winter in the form of a seedling or young plant, which survives under the snow and continues iits growth in the following spring. The seeds can lie dormant in the ground for many years and germinte afterwards when the soil is distributed. It is found in bloom throughout the whole growing season. It is distributed generaly all over Canada but is especially abundant in the Prairie Provinces. The plant when bruised has unpleasant odor and if the green parts are eaten by milch cows the dairy products are spoiled. A few seeds ground up with wheat seriously affect the quality of the flour.

The seed is liable to occur as an impurity in clover, cereals and flax. Owing to its smaller size it impossible to separate it from the cereals without difficulty. In grain fields that have been infested with this weed the stubble should be burned over after harvest so as to destroy any seeds that may be lying on the surface of the ground. Shallow cultivation should be practised to encourage the germination of seeds in the soil after which they should be ploughed under. If the ground is harrowed once or twice when the grain is about 3 inches high, many of the spring seedlings will be destroyed. Isolated plants that escape should be puled by hand when in flower. In badly infested fields summer fallow may be necessary. The cultivation should be frequent as green pods can go on ripening when under the soil. Chemical sprays do not injure this plant. Great care should be taken to ensure that the seed sown is free from this weed. —J. Adams, Assistant Dominion Botanist.

DOES IT PAY TO PAINT?

"The future durability of your home, barns or fences depends upon paint. Paint is not used primarily for ornament. It is for protection and economy," writes Charles E. White, Jr., in a recent issue of the Ladies Home Journal. Mr. White's remarks will attract more than casual interest at this time, in view of the broad educational campaign now being conducted in Canada with the approval of the Canadian Trade Commission. Paint prevents rust and decay, it saves more money a year than the efforts of the whole American fire and poilce forces combined, asserts Mr. White, and goes on to say:

"Cream walls with tan trimmings or white walls with a green roof may attract your attention, but color appearance is really of but secondary importance. Paint is used primarily for protection. Paint is the armor worn by your buidings to prevent annihilation by the elements. We paint our buildings to preserve them. Exposure to the atmosphere causes rot or rust in most building material. Paint has been found to be ac hemical combination of materials which prevent rust and decay. Your building will live as olng as the paint lives.

Paint This Fall
Because:

—of proper weather conditions.
—surfaces are now in their most receptive condition, practically every trace of moisture having been eliminated by the summer sun.
—the wood being dry it absorbs more readily, and the paint holds better.
—a surface needing protection should never be allowed to go over the winter without it.
—property needs more protection during winter than at any other time.

"Save the Surface and you save all."

Defying the weather on the farm

Find the up-to-date farmer who will stand for unnecessary waste. Find anyone, for that matter, with enterprise enough to accumulate property, who is willing to see it go to pieces.

And yet all over this country are farmers and others who are losing money unnecessarily every day, and do not appreciate it.

No matter how substantial your building may be, the elements will damage it if you give them the chance.

Never for one instant does the work of disintegration stop unless you stop it. Unless the surface of a building is protected by a surface coating the elements work away at it night and day.

Barns weaken and sometimes even partially collapse. Silos decay. Pens and coops go to pieces and are split up for wood. Outbuildings are replaced—all of which, too often happens long before the building's normal time.

Surface protection preserves buildings indefinitely. Disintegration is impossible if the surface is protected. Save the surface and you save all.

Whatever the material, whether wood, metal, concrete, cement, stucco or plaster, remember the great importance of surface protection. Save the surface and you save all.

THIS ANNOUNCEMENT *is issued by the Canadian Save the Surface Campaign Committee, for the purpose of educating the public in the Preservative and Protective value of Paint, Varnish and Allied Products for the Conservation of Property, and has received the approval of the Canadian Trade Commission in the following words:*

"The realization of the above objects will lead to employment during the Reconstruction Period and bears our entire approval.

A FARM FABLE

(By Peter McArthur in the Toronto Globe)

Once upon a time, in a fat agricultural district, the farmers and shepherds were much troubled by having their sheep killed and worried. It was suspected that the damage was the work of wolves, and the watchdogs did a lot of barking about the matter, because it raised the cost of living.

From time to time committees of watchdogs were appointed to investigate the situation, but they always brought in reports that the wolves of that district were nice and quiet wolves, that never did anythinig that a self-respecting wold need not be expected to do in the course of his business.

And the depredations to the flocks continued.

Moral:—It is not a bad idea to examine the mouths of the watch dogs once in a while to see if they have wool on their teeth.

THE FARMER AS A BUSINESS MAN

No other industry has gone forward as fast as farming—Canada's foremost business. During the last fifty years, yes, during the last ten years, farm methods have been revolutionizing. The automobile, the tractor, the cream separator, the telephone and dozens of other machines have done away with old, tedious labors.

All Canada knows that farming is a real business, that the farmer is a business man. And all expect him to employ the latest machinery and the most effective methods. No one believes that the farmer should deprive himself of the labor saving devices and comforts that are known to men in other industries.

Thousands of farmers are practicing scientific farming in their fields. they understand crop rotation. They are plowing deeper. And they are getting 100 per cent returns from their endeavors. Yet there are not enough farmers who have put that same amount of efficiency into their "office work." Yes, office work. Every farmer should have an office. He should have a desk and keep a set of books and records. Here is the way one farm paper talks to its readers in an editorial:

"Farming is a business requiring the same amount of capital and brains to make it successful as any other business of equal size.

"The man who makes the greatest success of farming is the one who runs is on business principles. He knows where his money goes, and how much it costs to produce his crops and feed his cows.

"Farmer Jones may not feel as much at home in his office as he does in the steer lot, but he knows that the time he spends there keeping his accounts or writing out letters on his typewriter, is time spent to good advantage. He knows that this work is just as effective as that in the field.

"Every farmer ought to have an office and use it. It will help him to make his farm more profitable."

The Government insists that farmers keep sufficient records so as to make correct returns for income tax. And, even were this not necessary. farmers nowadays want to know just where they stand, just where their earnings come from.

The core of this office should be a typewriter, the greatest piece of office machinery ever invented. No merchant, no lawyer, no manufacturer—no man needs a typewriter more than a farmer.

A farm represents a large investment, often larger than that of the average merchant. The capital of a farming business should be protected by modern methods just as much as that of the progressive, successful business man.

Why shouldn't a farmer have a printed letterhead? Like the banker, the lawyer, the storekeeper? Why shouldn't your letters go out to the world with a business-like appearance? Longhand letters are hard to read. They are hard to write. They are not neat. They look old-fashioned. Worst of all, longhand letters are unreliable. Mistakes occur because others can't read one's writing. Many mistakes are made in figures. Wrong shipments are made. Delays result.

With typewritten letters the figures are perfectly plain. No one can make a mistake. One or more carbon copies can be made of every letter, bill, etc., giving you a complete record of all transactions.

Typewritten letters receive first attention. If a person gets four typewritten letters and four longhand letters, he invariably reads the typewritten ones first and they receive quick attention.

What if your newspaper was all written in longhand? And it was the average kind of writing. Would you like it as well as a printed newspaper? You'd never read it. No, sir! People back up when they receive a long-

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The aderess must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on, as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue, which will always be found on the editorial page of the proceeding issle. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. MARITIME FARMER, Sussex N. B.

Five Ayrshire Bulls for Sale !

From good milking strain. All fit for service.

Prescott Blanchard,
Truro - Nova Scotia

hand letter. So few are easy to read.

We might as well be even more frank. Most of us write pretty poor letters. We scribble them off hastily and let the reader puzzle them out. And lots of people haven't the patience.

Picture two letters you might send out. Let one of them be on any old piece of paper, written in pencil in pencil in longhand.

Let the other be on a printed letterhead, with your name and address at the top. Let it be typewritten.

Which do you think the man at the other end would want to receive? Which would make the best impression? Which would show him that you were a business man? Certainly the typewritten letter.

Auto Tires $17.50

Fine non-skid tire for small cars, size 30 x 3½, fully guaranteed for 3500 miles

The Maritime Farmer begs to announce a substantial reduction in the price of non-skid tires for small cars, Fords, Chevrolets, Maxwells, etc. They are FIRSTS, fully guaranteed and we will sell them to you, provided you are a paid-up subscriber to the Maritime Farmer for $17.50 f. o. b. Sussex. Plain tires for $16.25, fully guaranteed for above mileage. Tubes for same size tire $2.90. These goods are all A1 stock and are made by a well known tire house. Of course these prices are for spot cash with order. The Maritime Farmer was able to take advantage of the recent break in the market and its large buying capacity to get you the benefit of this substantial cut in price. IT'S THE BEST BUY IN CANADA Today. Write the Auto Department, Maritime Farmer, Sussex, N. B.

A VERY VALUABLE BOOK

The Veterinarian, by Charles J. Korinck, V. S., is a work on the afflictions of horses, cattle, sheep, swine, poultry, etc., which every farmer should have in his home. The story of how treatment can best be administered is told in simple every-day English that any person can understand. The methods suggested by Prof. Korinek are simple and easily followed. The book will cost you seventy-five cents, postage paid. It may be the means of saving you as many dollars in the near future. How many men are there who meet trouble by writing to the Maritime Farmer or some other paper for information which will be found in the Veterinarian? It is strongly bound in cloth, has serviceable illustrations and is well indexed. Seventy-five cents will bring it to you.

FOR IMMEDIATE SALE

KEEP
Holstein-Friesian Cows

1. The Holstein-Friesian is a large vigorous cow, full of energy and abounding in vitality.
2. Her physical organization and digestive capacity are such that she is able to turn to the best advantage the roughage of the farm, converting the same into merchantable products.
3. She yields large quantities of most excellent milk, fit for all uses and especially suited for shipping purposes.
4. Heredity is so firmly established through her long lineage that she is able to perpetuate herself for the production of strong, healthy calves.
5. When for any reason her usefulness in the dairy is at an end, she fattens readily and makes excellent beef.

If you can't buy a herd, buy a heifer

ST. STEPHEN EXHIBITION

THE ST. STEPHEN EXHIBITION

The Charlotte County Exhibition annually held at St. Stephen, N. B., became international in character this year when at the time of their eleventh annual fair, September 9th to 12th, the contests were open to exhibitors from the Maritime Provinces and Washington County, Maine.

The St. Stephen Fair has, under the skilful management of Mr. W. S. Stephen and a capable board of energetic working directors, been making steady progress. The innovation of admitting exhibitors from beyond the limits of Charlotte County this year is one which we hope will be continued. The introduction of such magnficent herds and flocks as were seen at the 1919 Fair—Snowball's Shorthorns and Dickies' Holsteins and King Shrops and Cheviots, as well as Jewett's Clydes, Percherons and Standard Breds will have the effect of creating an ideal in the minds of the local exhibitors who have heretofore been accustomed to show flocks and herds without bestowing any particular care upon them in the way of fitting or tidying up for the showring. There is a considerable lot of fairly good stock in the hands of Charlotte County breeders that, with a little fitting and some extra care, would be quite presentable and make a good showing.

The money prizes won at the show do not begin to equal the value that the breeder receives from the publicity his flocks and herds receive from show ring winnings. Wise is the breeder who brings his stock to the fairs in a presentable condition and who can show the public the records of performance of the animals in his herd. Good appearance coupled with good performance tends to an increased demand and sale of stock at remunerative prices.

The attendance at the St. Stephen Fair was all that could be desired but the weather man did not favor the show with a brand of weather that would have a tendency of creating much enthusiasm. Cloudy and cool were the first two days of the fair, while the last two days brought down pours of rain. Despite this fact, however, there was a record attendance, so much so that the grounds which have been considerably extended durin the past year, were taxed to their utmost capacity in accommodating the thousands that thronged through the buildings, midway and other sections of the fair grounds.

The old horse barns have been torn down and new and more commodious horse and cattle barns erected to the rear of the old site on an area purchased to give increased accommodation. We believe the management proposes the erection of other buildings during the coming year. The grounds are splendidly located and a railway siding on the fair grounds gives the stockmen a chance to unload and load the stock with minimum labor, a feature which is very much appreciated by all who have anything to do with the showing of live stock. The citizens of St. Stephen have reason to be proud of their exhibition plant. The biggest drawback to the St. Stephen Exhibition in the way of getting exhibits from outside points is the fact that all coming from east of St. John must be transferred over two lines of railway, which makes the freight charges almost prohibitive. This is a feature that the management of the show will do well to use their best efforts towards getting the very lowest possible freight rates conceded to their exhibitors.

In the live stock department, Snowball's Shorthorns, Clydesdales and Sheep, Jewett's Clydesdales, Percherons and Standard Breds, Dickies' Holsteins, the Sir Wm. Van Hornr estate Ayrshires and Cyldesdales, Tom McDonald's swine and Kings Shrops and Cheviots were out in the pink of condition. Martin Reid, A. T. Reed, Freeman Lever, Walter Howland and Manzer Moffatt, Polleys Forsythe and others had their herds and flocks out in good working field fit. The respective herds and flocks contained some promising, useful looking animals that with some extra fitting and trimming would put up a good appearance. The Van Horne Estate Ayrshires were a particularly smooth and well fitted lot.

In the Horned Dorset shearling ram class a first prize winner at this year's Toronto show went down to second place to a ram bred and exhibited by R. A. Snowball, of Chatham, N. B.

The judges of the respective classes were:

Heavy Horses.—T. G. Hetherington, B.S.A., Fredericton, N. B.

Light Horses.—Jas. Easton, Chatham, N. B.

Sheep and Swine.—T. G. Hetherington.

Cattle.—Prof. J. P. Sackville, O.A.C. Guelph, Ont.

Poultry.—J. Clarke, Cainsville, Ont.

Domestic.—Miss Elizabeth Nutter, Fredericton.

Fancy.—Mrs. E. McL. Hatt, Fredericton.

Agricultural Products.—S. J. Moore, Truro, N. S.

Honey—L. T. Floyd, Fredericton.

Dairy Products.—H. Coleman, Sussex.

The Agricultural Hall was filled to its utmost capaclty with the products of the field and garden and made the best display ever seen at a Charlotte County fair. There was a good display of fruit. The Domestic lines were hardly up to the standard of some previous years in point of quantity and while the same may be said of the fancy work department, the quality of the workmanship excelled that of last year when the display was more extensive.

There was a pretty fair showing of poultry. Mr. McCullough, Poultry Superintendent for the province, had a demonstration exhibit on the grounds consisting of incubators with newly hatched chicks, brooders and a colony house in which he demonstrated the proper care of young chicks during the first few days while being transferred from incubator to brooder and colony house. His demonstrations were much appreciated by interested poulrty keepers.

The Dominion Experimental Station, Fredericton, had an instructive and interesting display of the products of the farm interspersed with placards bearing some sage morsels of advice to the farmer.

The Dominion Live Stock Division also had a booth in which their representative, J. K. King, B.S.A., talked sheep and explained to many interested parties the various plans whereby the Division can help the sheep growers in procuring and maintaining larger and better flocks.

There was not much competition in any section of the pure bred classes of live stock.

In Clydesdales Snowballs' Baron's Own had an easy first over H. C. Jewet's Dr. McCoy. Another Snowball entry took third place, leaving a trim stallion shown by Mr. Spinney, of St. George, just outside the money.

There were three entries in the aged mare class, Sweet Mary and Seaham Bonnie, a pair of mares shown by the Van Horne estate sandwiching Rose of Liberty, shown by R. A. Snowball.

The only Percherons on the grounds were Montgomery Ward and Arlon shown by H. C. Jewett, who also had the first, second and third prize Standard Bred Stallions in Exposer, Harvest Hope and Native Worthy respectively.

Snowball's Shorthorns had no competitors, Dickie Bros., of Truro, N.S., easily captured first and second monies in every section in which they had entries. Their competitors were Chas. Maxwell, St. Andrews, Manzer Moffatt, Wm. Moffatt and M. S. Lyons & Sons, of Calais, Me.

The Van Horne Estate Ayrshires were easily first in their respective sections, one of their bulls, a junior yearling capturing the St. Croix Courier Silver Cup for the best bull at the exhibition owned by a Charlotte County Exhibitor.

The Coven Hoven Stock Farm's special prizes for the best pure bred bulls between one and two years old were won by Manzer Moffatt's, R. A. Snowball's and M. S. Lyons & Son's Holsteins in first and third positions sandwiching a Shorthorn.

The best grade calves for which the Canadian Bankers' Association offers prizes were won by Agnes Reed and Alice L. Lever, of Rollingdam.

Following is a list of the prize winners:

Clydesdale Horses

Stallion, 4 years old and upwards—1 and 3, R. A. Snowball, Chatham, N. B.; 2, H. C. Jewett, Fredericton, N. B.

Stallion, 1 year old—1, R. A. Snowball.

Filly, 3 years old—1 and 3, Sir Wm. Van Horne Estate, Coven Hoven Farm, St. Andrews, N. B.

Matched Team—1, Coven Hoven Stock Farm; 2, R. A. Snowball.

Standard Breds

Stallion, 3 years old—1, 2 and 3, H. C. Jewett, Fredericton.

Brood Mare—1, Wilfred Todd, Milltown.

Filly or Gelding, 3 years old and upwards—1, A. H. White, Moore's Mills; 2 and 3, W. F. McGibbon, Moore's Mills.

Foal of 1919—1, Wilfred Todd.

Carriage Horses

Filly or Gelding, 3 years old and upwards to halter—1, Hugh Love, St. Stephen.

Mare or Gelding in harness—1, John Webber, St. Stephen; 2, J. W. Robinson, St. Stephen; 3, Herbert Dick, Moore's Mills.

Matched Team—2, D. R. Chown, Oak Hall.

Hackneys

Stallion, 3 years old—1, R. A. Snowball.

Filly, 2 years old—1, R. A. Snowball.

Saddle Horses

Filly or Gelding, 3 years old—1, Hazen Linton, St. Stephen.

Percherons

Stallion, 3 years old—1 and 2, H. C. Jewett.

Agricultural Horses

Brood Mare—3, John Trafton, Lynnfield.

Mare, 3 years old—1 and 2, Rown Trafton, Lynnfield; 3, Louis Asker, St. Stephen.

Filly, 2 years old—1 and 2, Polleys Forsythe, Little Ridgeton.

Foal of 1919—3, John Trafton.

Matched Team—1, Rown Trafton; 2, Peter McLeod, Oak Bay; 3, Polleys Forsythe.

Heavy Draft

Mare or Gelding, 3 years old—1, Wm. Moffatt; 2, R. A. Snowball; 3, Geo. H. Budd, St. Stephen.

Filly or Gelding, 2 years old—1, Chas. Maxwell, St. Andrews.

Filly, 1 year old—1, R. A. Snowball.

Matched Team—1, Wm. Moffatt; 2, Manzer Moffatt; 3, Geo. H. Budd.

Ponies

12 hands or under—1, Carman Ganong, St. Stephen; 2, Jack Pike, St. Stephen.

Pair—1, Philip and Whidden Ganong.

12 hands up to 13½ hands—1, H. C. Purves, St. Stephen.

BEEF CATTLE

Shorthorns

Bull, 3 years and over (1)—1, R. A. Snowball, Chatham, N. B.

Bull, senior yearling (1)—1, R. A. Snowball.

Bull, senior calf—1, R. A. Snowball.

Bull, junior, calf—1 and 2, R. A. Snowball.

Cow, 4 years old—1, 2 and 3—R. A. Snowball.

Heifer, 2 years old—1, R. A. Snowball.

Heifer, senior yearling—1, R. A. Snowball.

Heifer, junior yearling—1, R. A. Snowball.
Heifer Calf, senior—1 and 2, R. A. Snowball.
Heifer, calf, junior—1, and 2, R. A. Snowball.
Aged herd—1, R. A. Snowball.
Breeder's young herd—1, R. A. Snowball.

DAIRY CATTLE

Ayrshires

Bull, 3 years old and upwards—1, A. T. Reed, Rolling Dam.
Bull, junior yearling—1, Sir Wm. Van Horne Estate, St. Andrew's, N. B.; 2, A. T. Reed.
Bull, senior calf—1 and 2, Sir Wm. VanHorne Estate; 3, Freeman Lever, Rolling Dam; 4, Martin Reed, Rolling Dam.
Bull, junior calf—1 and 2, Sir Wm. Van Horne Estate; 3, A. T. Reed.
Cow, 4 years and upwards—1, Walter Howland, Moore's Mills; 2 and 3, A. T. Reed, Rolling Dam.
Dry Cow, 3 years old—1, A. T. Reed.
Cow, 3 years old—1, A. T. Reed.
Cow, 2 years old—1, Martin Reed, Rolling Dam.
Heifer, Senior yearling—1, Sir Wm. Van Horne Estate; 2, A. T. Reed; 3, Martin Reed.
Heifer, junior yearling—1 and 2, Sir Wm. Van Horne Estate; 3, A. T. Reed.
Heifer, senior calf—1 and 2, Sir Wm. Van Horne Estate; 3, A. T. Reed.
Heifer, junior calf—1 and 2, Sir Wm. Van Horne Estate; 3, Martin Reed.
Herd, aged—1, A. T. Reed.
Breeders' young herd—1, Sir Wm. Van Horne Estate; 2, A. T. Reed; 3, M. A. Reed.
Bull, any age—Diploma, Sir Wm. Van Horne Estate.
Female, any age—Diploma, Sir Wm. Van Horne Estate.

Jerseys

Bull, 3 years old—1, J. Polleys Forsythe, Little Ridge.
Cow, 4 years old—1, Hazen Linton, St. Stephen; 2, Thos. McClure, St. Stephen.
Cow, 2 years old—1, Frank McGarrity, Milltown.
Heifer, senior yearling—1, Hazen Linton.

Holsteins

Bull, 3 years old—1, Dickie Bros., Truro, N. S.; 2, Chas. Maxwell, St. Andrews.
Bull, 2 years old—1, Manzer Moffatt, St. Stephen.
Bull, junior yearling—1, M. S. Lyons & Son, Calais, Me.
Bull, senior calf—1 and 2, Dickie Bros.; 3, Manzer Moffatt.
Bull, junior calf—1, Dickie Bros.; 2, Wm. Moffatt.
Cow, 4 years old—1 and 2, Dickie Bros.; 3, Wm. Moffatt, St. Stephen.
Dry Cow, 3 years old—1 and 2, Dickie Bros.
Cow, 3 years old—1, Manzer Moffatt; 2, M. S. Lyons & Son.
Breeders' young herd—1, Dickie Bros.; 2, Manzer Moffatt.
Best Bull—Diploma, Dickie Bros.
Best Female—Diploma, Dickie Bros.

Fat Cattle

Best beef animal—1, Manzer Moffatt.
Best pair fat cattle—1, Manzer Moffatt.

Beef Grades

Cow, 3 years old—1, R. A. Snowball; 2, Wm. Moffatt.
Heifer, 1 year old—1, Polleys Forsythe.
Heifer Calf—1, Wm. Moffatt.
Steer, 2 years old—1, Wm. Moffatt.
Steer, 1 year old—2 and 3, Polleys Forsythe; 1, Wm. Moffatt.

Grade Jerseys

Cow, 4 years old—1, Wm. Moffatt; 2 and 3, J. Polleys Forsythe.
Cow, 3 years old—1 and 2, Polleys Forsythe.
Heifer, 2 years old—1, Polleys Forsythe; 2, Wm. Moffatt.
Heifer, 1 year old—1 and 2, Polleys Forsythe.
Heifer Calf, senior—1 and 2, Polleys Forsythe.
Heifer, junior calf—1 and 2, Polleys Forsythe; 3, Aubrey Stevenson, St. Stephen.
Grade herd—1, Polleys Forsythe.

Grade Ayrshires

Cow, 4 years old—1, H. Freeman Lever.
Heifer, 2 years old—1, Walter Howland; 2, Freeman Lever.
Heifer, 1 year old—1, H. Freeman Lever; 2, Albion Moffatt.
Heifer, senior calf—1, H. Freeman Lever.
Heifer, junior calf—1, H. Freeman Lever.
Herd—1, H. Freeman Lever.

Grade Holsteins

Cow, 4 years old—1, M. S. Lyons & Son; 2, Manzer Moffatt.
Cow, 3 years old—1, M. S. Lyons & Son; 2, Howard Densmore, St. Stephen; 3, F. Acker.
Cow, 2 years old—1, Albion Moffatt; 2, Manzer Moffatt.
Heifer, 2 years old—1, John Trafton, Lynnfield; 2, Wm. Moffatt; 3, Albion Moffatt.
Heifer, 1 year old—1, M. S. Lyons & Son; 2, Albion Moffatt; 3, Manzer Moffatt.
Heifer, senior calf—1, Albion Moffatt.
Heifer, junior calf—1, Chas. Maxwell, St. Andrews; 2, John Densmore.
Herd—1, M. S. Lyons & Son; 2, Albion Moffatt; 3, Manzer Moffatt.

French Canadian Grades

Cow, 4 years old—1, L. B. Mitchell, St. Stephen.
Heifer, 2 years old—1, Milton McCready, St. Stephen.
Heifer, 1 year old—1, L. B. Mitchell.
Heifer, senior calf—1, Milton McCready.

SWINE

Improved Berkshires

Boar, over 1 yr., under 2 yrs.—1, Polleys Forsythe, Little Ridge.
Sow, over 1 yr., under 2 yrs.—1, Polleys Forsythe; 2, Martin Reed, Leverville.
Sow, under 6 mos.—1 and 2, Polleys Forsythe, Little Ridge.

Improved Yorkshires

Boar, over 6 months ,under 1 yr.—1, Fredric Lever, Rolling Dam.
Sow, over 2 yrs.—1, Albion Moffatt, St. Stephen; 2, Fredric Lever.
Sow, 2 yrs.—1, Daniel McLeod, Oak Bay; 2, Albion Moffatt.
Sow, over 6 months, under 1 yr.—1, Thomas McDonald.
Breeding Sow with litter—1, Wm. McLeod, Oak Bay.

Any Other Pure Breed

1, Albion Moffatt, Polan China Boar.
Sow, over 6 months, under 1 yr.—1, Robbie Babb, St. Stephen; 2, Sterling Babb, St. Stephen.
Sow, under 6 months—1, Albion Moffatt.
Breeding Sow with litter—1, Albion Moffatt, St. Stephen.

Fat Pigs (Boars excluded)

Spring Pig—1, Sterling Babb; 2 and 3, Daniel McLeod.

Grades

Sow, over 6 months, under 1 yr.—1, Thomas McDonald, St. Stephen; 2, Manzer Moffatt, St. Stephen.
Breeding Sow with litter—1, Manzer Moffatt.
Special prize open only to members of Boy Breeders' Clubs in New Brunswick.

Yorkshires

Sow, over 1 yr.—Fredric Lever, Rolling Dam.
Boar, over 4 months, under 1 yr.—1, Frederic Lever.

SHEEP

Leicesters

Ram, 2 shears and over—1, John A. Bell, Milltown.

Shropshires

Ram, 2 shears and over—1, John H. King & Son, Sussex; 3, Howard Trafton, Lynnfield.
Shearling Ram—1, John H. King & Son; 2, R. A. Snowball, Chatham.
Ram Lamb—1, John H. King & Son; 3, Howard Trafton.
Ewe, 2 shears and over—1, John H. King & Son; 3, Howard Trafton.
Shearling Ewe—1, John H. King & Son; 3, Howard Trafton.
Ewe Lamb—1, 2 and 3—John H. King & Son.
Pen, graded—1, John H. King & Son; 3, Howard Trafton.
Pen Lambs—John H. King & Son.

Cheviots

Ram, 2 shears and over—1 and 2, Geo. King, Sussex.
Shearling Ram—1, Geo. King.
Ram Lamb—1, 2 and 3, George King.
Ewe, 2 shears and over—1, 2 and 3, George King.
Shearling Ewe—1, Geo. King.
Ewe Lamb—1, 2 and 3, Geo. King.
Graded Pen—1, 2, Geo. King.
Pen Lambs—1, Geo. King.

Dorset Horns

Shearling Ram—1, R. A. Snowball; 2, Manard Smith, Bathurst.
Ram Lamb—1 and 2, Martin Reed, Leverville; 3, Walter Howland, Moore's Mills.
Ewe, 2 shears and over—1, R. A. Snowball; 2, Martin Reed; 3, Walter Howland.

Graded Long Wool

Pr. Ewes, 2 shears and over—1, John A. Bell, Milltown, N. B.; 2, Stanley J. Libbey, Milltown, N. B.
Pair Ewes, shearling—2, John A. Bell.
Pair Lambs—1, John A. Bell.
Pen—2, John A. Bell.

Grades, Medium Wool

Pair Ewes, 2 shears and over—1, R. A. Snowball; 2, Alex. Forsythe, Little Ridge; 3, H. Freeman Lever, Rollingdam.
Pair Ewes, shearling—1, R. A. Snowball; 2, H. Freeman Lever; 3, Walter Howland.
Pair Lambs—1, R. A. Snowball; 2, Coleman Gillis, St. Stephen; 3, Walter Howland.
Pen—1, R. A. Snowball; 2, H. Freeman Lever; 3, Walter Howland.

Fat Sheep, any Breed or Grade

Ewe, over 1 yr.—1, R. A. Snowball; 2, Walter Howland.
Ewe Lamb—1, R. A. Snowball; 2, Frank Morrison, St. Stephen; 3, H. Freeman Lever.

POULTRY

Fowl

Anconas Hen—1 and 2, Howard Dinsmore, St. Stephen.
Brahmas, Light Cock—1, Frank McGarrity, Milltown, N. B.
Brahmas, Light Hen—1 and 2, Frank McGarrity; 3, Clarence McCarty, Calais, Me.
Buttercup Sicillian Hen—1, Cecil Johnson, Moore's Mills.
Game, any variety cock—1, Geo. Tourtillotte, St. Stephen.
Game, A. V. Hen—1, 2, and 3—Geo. Tourtillotte.
Houdan Cock—1, Frank Wheelock, St. Stephen; 2, Mrs. Fred Graham, St. Stephen.
Houdan Hen—1, Mrs. Fred Graham.
Hamburgs, Silver Spangled Hen—1, Thomas Bartlett, St. Stephen.
Leghorns, White S. C. Cock—1, Frank Wheelock.
Leghorn, White S. C. Hen—1, and 2, Thomas Vanstone, St. Stephen.
Leghorn, Brown S. C. Cock—3, Manzer Moffatt.
Leghorn, Brown S. C. Hen—1, Manzer Moffatt; 2, Thomas Bartlett.
Leghorns, Black S. C. Hen—1, W. S. Stevens, St. Stephen.
Orpingtons, Buff Hen—1 and 2, A. C. McCready, St. Stephen.
Orpington, White Hen—1 and 2, Frank McGarrity.
Plymouth Rocks Barred Cock—1, W. S. Stevens, St. Stephen; 2, Aubrey Stevenson, St. Stephen.
Plymouth Rocks, Barred Hen—1 and 3, W. S. Stevens; 2, Aubrey Stevenson.
Plymouth Rock, White Cock—1, E. B. Greenlaw, Calais, Me.
Plymouth Rock, White Hen—1, E. B. Greenlaw.
Plymouth Rock Columbia Hen—1 and 2, Gustav Klein, Milltown, N. B.; 3, Ernest Klein, Milltown, N. B.
Rhode Island Reds, S. C. Cock—1 and 2, Aubrey Stevenson; 3, Milton McCready, St. Stephen.
Rhode Island Reds, S. C. Hen—1 and 2, Milton McCready, St. Stephen.
Wyandottes, Silver Laced Cock—1, Gustax Klein; 2, Ernest Klein.
Wyandottes, Silver Laced Hen—1, Gustav Klein; 2 and 3, Ernest Klein.
Wyandottes, White Cock—1, Milton Maxwell, St. Stephen; 2, Thomas McClure, St. Stephen.
Wyandottes, White Hen—1 and 2, C. H. Maxwell, St. Stephen; 3, Milton Maxwell.
Wyandottes, Columbia Hen—1, Gustav Klein; 2 and 3, Ernest Klein.

Chickens

Light Brahmas, Cockerel—1 and 2, Frank McGarrity.
Light Brahmas, Pullet—1 and 2, Frank McGarrity.
Game, any variety, Cockerel—1 and 2, Geo. Tourtilotte.
Game Pullet, A. V.—1 and 2, Geo. Tourtilotte.
Silver Spangled Hamburg Cockerel—1, Thomas Bartlett.
Silver Spangled Hamburg Pullet—1, Thomas Bartlett, St. Stephen.
Leghorns, S. C. Cockerel—1 and 3, Thomas Vanstone; 2, Ernest Klein.
Leghorns, S. C. Pullet—1 and 2, Thomas Vanstone.
Leghorns, Brown S. C. Cockerel—1, Cecil Johnson, Moore's Mills; 2, Manzer Moffatt.
Leghorns, Brown S. C. Pullet—1, Manzer Moffatt; 2, Cecil Johnson.
Leghorns, Brown Rose Comb Cockerel—1, Ernest Klein.
Leghorns, Brown Rose Comb Pullet—1, Ernest Klein.
Orpingtons, Buff Cockerel—1, A. C. McCready.
Orpington White Cockerel—1 and 2, Frank McGarrity; 3, Mrs. Arthur Livingston.
Orpington, White Pullet—1 and 2, Frank McGarrity.
Barred Plymouth Rock Cockerel—1 and 2, W. S. Stevens; 3, Aubrey Stevenson.
Barred Plymouth Rock Pullet—1, W. S. Stevens; 2, Aubrey Stevenson; 3, John Goode, Calais, Me.
Plymouth Rock White Cockerel—1, E. B. Greenlaw.
Plymouth Rock, White Pullet—1, E. B. Greenlaw.
Plymouth Rocks Buff Cockerel—1 and 2, Ernest Klein; 3, Gustav Klein.
Plymouth Rocks Buff Pullet—1, Gustav Klein; 2 and 3, Ernest Klein.
Plymouth Rocks Partridge Cockerel—1, Ernest Klein; 2, Gustav Klein.
Rhode Island Reds, S. C. Pullet—1, 2 and 3, Aubrey Stevenson.
Wyandottes Silver Laced Cockerel—1 and 2, John Hanson, Calais, Me.; 3, Gustav Klein.
Wyandottes, Silver Laced Pullet—1 and 2, Ernest Klein; 3, John Hanson.
Wyandottes, White Cockerel—1, 2 and 3, C. H. Maxwell, St. Stephen.
Wyandottes, White Pullet—1, C. H. Maxwell.

Breeding Pens, Adult Birds

Brahmas, Light—1, Clarence McCarty, Calais, Me.; 2, Parker Grimmer, St. Stephen.
Leghorns, White S. C.—1, Thomas Vanstone.
Leghorns, Brown S. C.—1, Manzer Moffatt.
Orpingtons, Buff—1, A. C. McCready.
Rhode Island Reds, S. C.—3, Howard Dinsmore, St. Stephen.
Wyandottes, Silver Laced—1, Ernest Klein.
Wyandottes, White—1, C. H. Maxwell.
Wyandottes, Columbian—1, Ernest Klein.

Breeding Pens, Chicks

Brahmas, Light—1 and 2, Frank McGarrity.
Leghorns, White S. C.—1, Thomas Vanstone.
Leghorns, Brown S. C.—1, Cecil Johnson.
Leghorns, Brown Rose Comb—1, Ernest Klein.
Orpingtons, White—1, Mrs. Arthur Livingston, Moore's Mills.
Wyandottes, Silver Laced—1, Gustav Klein; 2, Ernest Klein.
Wyandottes, White—1, 2, C. H. Maxwell.

Mating Pens

Barred Plymouth Rocks, mated to produce cockerels—1, John Goode.

Barred Plymouth Rocks, mated to produce pullets—1, Aubrey Stevenson.

Mating Pens, Chicks

Barred Plymouth Rocks, mated to produce pullets—1, John Goode; 3. Will Finkell, St. Stephen.

HONEY and APAIRY SUPPLIES

Comb Honey in sections—1, Gerald Todd, Milltown, N. B.

Best Liquid Extracted (Light)—1, Gerald Todd; 2, Allie Wilson, St. Stephen.

Best Liquid Extracted (Dark)—1, Allie Wilson.

Best Granulated Honey in glass—1, Gerald Todd; 2, Allie Wilson.

Best display honey prepared for market—1, Gerald Todd; 2, Allie Wilson.

Purest and best Beeswax—1, Walter Howland, Moore's Mills; 2, Allie Wilson.

Best assortment Apiarian supplies—1, Allie Wilson.

Largest and best display of honey bearing plants—1, Allie Wilson; 2, Gerald Todd; 3, F. Holmes Maxwell, St. Stephen.

Bees

Best colony of Italian Bees in observation hive—1, Allie Wilson; 2, Gerald Todd.

Best colony of black bees in observation hive—1, Gerald Todd; 2, Allie Wilson.

L. T. FLOYD, Judge.

HORTICULTURE

Best collection Apples—1, W. C. Arnold, St. Stephen; 2, Frank Scott, St. Stephen; 3, W. F. McGibbon, Moore's Mills.

Sweepstakes

Most artistic and comprehensive exhibit of fruit grown on any one farm in Charlotte Co., in natural and preserved state—1, Frank Scott; 2, Mrs. Geo. Young, Oak Bay.

DAIRY

Butter, tub or crock—1, Ella Lindsay, Tower Hill, 94.9; 2, Miss Alice Nixon, Waweig, 93.3; 3, H. Freeman Lever, Rollingdam, 92.9; 4, Arthur Claxton, Oak Bay, 92.5; 5, W. E. MacCarlie, Oak Bay, 91.4.

Printed or fancy package—1, Arthur Claxton, Oak Bay, 96.6; 2, H. Freeman Lever, 95.5; 3, Mrs. Leonard Jackson, St. Stephen, 95.2; 4, Ella Lindsay, 94.8; 5, Mrs. A. T. Reed, Rollingdam, 94.7; 6, W. E. MacCarlie, 94.5; 7, Miss Alice M. Nixon, 94.4; 8, Samuel Bamford, Little Ridge, 93.7.

Butter in granulated form—1, Samuel Bamford; 2, H. Freeman Lever; 3, Mrs. Eva Nicoll, Calais, Maine.

H. W. COLEMAN, Judge.

Best collection of Grain grown in Charlotte County—1, W. Simpson, Waweig.

Best collection of grains in the straw—1, W. Simpson; 2, Hampden Gilmore, Bonny River.

Best collection of potatoes—1, Frank Scott, St. Stephen; 2, I. R. Sprague, Princeton, Me.; 3, Geo. H. Voutt, St. Stephen.

Best collection Garden Vegetables—1, Eliza McBride, St. Stephen; 2, Wallace Sullivan, St. Stephen; 3, W. F. McGibbon, Moore's Mills.

Best collection Herbs—1, W. F. McGibbon; 2, Geo. H. Voutt; 3, Charles Voutt, St. Stephen.

Largest Pumpkin—1, Allie Wilson, St. Stephen, 109 lbs.

ST. JOHN VALLEY EXHIBITION

Beautiful for situation and cinveniently arrranged in every detail is the new exhibition plant at Cornhill's Island of the Woodstock Agricultural Society, which held its first exhibition in its new home on Sept. 9th to 12th. The Woodstock Agricultural Society membership comprise the majority of the most progressive business men of the town—men who have a vision of the possibilities of Agriculture in their County and who are at all times willing to do what they can to encourage the industry that lies at the very foundation of the prosperity of their town.

For a number of years they have been planning the erection of an exhibition plant on the island formed where the St. John River for a space divides its waters opposite their thriving town. The island consists of a porous, sandy soil that dries quickly after a rain storm and is fringed with magnificent trees of the principal varieties found in our New Brunswick forests. The island throughout is a natural park whose beauties the citizens of Woodstock, thanks to the generosity of the Cornhill Estate, are able to enjoy—recreation, athletic, picnic and exhibition grounds combined in a manner not excelled in any other part of Canada. The island is reached by a sloping plank driveway from the middle of the main bridge that spans the St. John River at the upper end of the island. The arrangement is such that thousands of cars and teams may enter and leave the grounds and be parked on the island without in any way interfering with the safety or comfort of the army of pedestrians who visit the fair.

Condition brought about by the recent war prevented the Woodstock Agricultural Society from putting their plans sooner into effect. However, on the conclusion of the war the Woodstock men got busy to undertake the carrying out of their plans and despite the head shakers of the worldly wise proceeded with an abounding spirit of optimism to erect one of the finest exhibition plants in Eastern Canada.

They did not proceed in a haphazard way. They consulted specialists in planning, employed a competent thchitect, Henry Post, who has proven his ability nobly and well by the manner in which he has so expeditiously erected the various buildings, fourteen in number. Ten buildings are 140x40; the grand stand is 150x50 and seats 2,000 people with 28 ft. post; the main building is 210x86 with 28 foot posts. There are also 149 box stalls. All building sare on concrete foundations and have cost upwards of $35,000 . With an average of 30 men those buildings were erected in 15 weeks with the exception of the cupola and exterior trimmings of the main building. There is not an unsightly building on the grounds and the live stock building have the place of honor, being so located that the visitor to the fair may visit the various departments of the live stock section with comfort and ease.

The visitor to whom the midway and the horse races has no charms is not compelled to traverse either one of these sections before reaching the agricultural and live stock shows.

The initial show on the new grounds was international in character, being open to exhibitors from Canada and the State of Main. Ontario, Quebec, Maine, Nova Scotia, Prince Edward Island and New Brunswick were present with their herds and flocks. As the exhibition gets better know of the breeders it will be more extensively patronized than it was this year. The fact that Woodstock may be reached by both Canadian National Railways and the Canadian Pacifis Railway will make it a favorite place for the meeting in friendly contest of the Upper and Lower Province and Maine State Breeders.

Whle there was a fair showing of good Shorthorn, Aberdeen, Angus, Holstein, Ayrshire, Guernsey, Jersey and Brown Swiss catle the competition was not very keen in any particular section as will be seen by the list of awards which we publish herewith.

The Percheron classes brought out horses owned by C. E. Allen, of Hartland, Geo. H. Benn, of Hodgen, Me., Warren C. Bull, Woodstock and Chas. Gray, Upped Woodstock.

John O., owned by Mr. Allen, was first in the aged stallion class, followed in second place by Gusham ,owned by Mr. Benn. Readers of Maritime Fairs reports will remember Gusham as a prize winner in former years while in the hands of H. C. Jewett, of Fredericton. There were a number of Percherons were shown that were not awarded prizes by the judge, D. J. Griegg, Corners, P. Q., owing to features that were detrimental to good horse breeding. The most outstanding Clydesdale at the show was Baron Squire, an erstwhile champion of the Maritime Horse Show at Amherst, N. S., while in the hands of McFarland Bros., of Fox Harbor, N. S.

There was a fair competition in driving, general purpose and agricultural horses. The competition was not so keen in the heavy draft class, despite the fact that there are some splendid teams in Carleton County.

Mc ntyre Bros., Sussex, N. B., John Ralston, Truro, N. S., H. W. Rogers, Woodstock, and Clover Nook Stock Farm had the main entries in Ayrshires. McIntyre Bros. aged bull Morton Mains Awarth was champion male and sire of four animals get of one sire as well as first with three of his get. Their Spring Brook Nellie was dam of first prize two progeny of one cow. John Ralston's Eastcourt Primrose led the way with two of his offspring.

Mr. Laird & Son, Kelvin Grove, P. E. I., W. L. Carr, Woodstock, Chas. P. Palmer, Woodstock, A. J. Raymond, Woodstock,, J. H. Millbury, Woodstock, Harry Reid, Woodstock, H. C. Cochrane, Victoria and F. B. Carvell, Woodstock, were exhibitors and prize winners but the majority of the awards went to the well fitted Laird herd. Horne Bros. Rollies had no competition.

Clover Nook Stock Farm, John. W. Purvis, Woodstock, W. H. Lindsay, Woodstock, Earle B. Avery, Woodstock, W. Carr, Warren C. Bull, F. K. Brown, Upper Brighton, exhibited Holsteins. Purvis' two year old champion Korndyke Pietje, a grandson and great grandson of Pontac Korndyke, was first with three of his get. He was also the sire of the best four calves bred by exhibitor and three animals get of one sire.

Clover Nook's Artis Rooker Posch was first with three of her progeny.

J. H. Semple had everything his own way in Jersey class excepting the first prize aged cow and the second prize two year old heifer, which were shown by A. J. Raymond, Woodstock.

Geo. H. Benn, Sodgen, Maine, had a clean sweep in Guernseys with a herd that would stand a fair amount of competition.

W. A. Jolly, Waterloo, Que., and Ralph H. Libby, Stanstead, Que., divided honors in the Brown Swiss classes. The competition in both beef and dairy grades was not at all keen.

A. R. Ness, of McDonald's College, P. Q., placed the awards in all cattle classes.

Poultry

Fredericton and Woodstock poultry men vied with each other in the poultry classes. Geo. Wilson, of the Dominion Poultry Division, placed the awards.

Sheep

There was a good showing of sheep. John Ralston, of Truro, and D. G. Purvis, of Woodstock, showed Leicesters. J. M. Laird and Geo. Boswell, of Prince Edward Island, and Clover Nook Stock Farm and Ed. Barrett showed Oxfords. There was battle royal in the Shropshire classes between Geo. Boswell's flock and that of A. Ayre, Hampton, Ont., with a few individuals shown by Clover Nook Stock Farm. Chas. Nunn and Lorne Nunn of Prince Edward had two splendid Hampshire flocks.

A .Ayre had nearly everything his own way in the Cheviot class.

Geo. Boswell, A. Ayre and Clover Nook aFrm locked horne in the Dorset class.

Horne Bros., of Winsloe, P.E.I., had some nice Suffolks.

A. E. Raymond, of Woodstock, and R C. Fishe, of Florenceville placed the awards.

Swine

Swine made a splendid showing at Woodstock. Messrs. Raymond and Fishe placed the awards. Shaw Bros. of Hartland and J. R .Semper, Truro, exhibited their splendid Berkshires. Clover Nook had a walk over in Tamworths. Ralph Libby showed some nice Poland Chinas. The White Chester and Yorkshire classes were comparatively few in numbers.

Glen Campbell and Roland Brooks of the Arthurette Boys Pig Club showed some nice Yorkshires and Chesters and their success should be an inducement to the members of other clubs to bring their stock to the shows.

The Agricultural display in the centre of the main building was spread out over too great an area to look well at first glance but the oftener one viewed the display the better it looked. There was a nice display of fruit A. C. Gorham, B.S.A., Sussex, placed the awards.

The Dominion Experimental Farm and the Entomological Branch had booths in the building where their representatives were kept busy talking to the many farmers who called on them for information There was no busier man in the aggregation than Geo. E. Sanders, the spraying expert, who showed the farmers how they can reduce their bills for spraying materials by the use of cheaper combinations which he has found do the work cheaply and efficiently.

The Woodstock Vocational School had a display of the products of their garden and of the work done in the manual training and domestic departments that was very creditable to the school. The ladies domestic and fancy work was of high standard workmanship.

Woodstock has an exhibition plant second to non and the farmers of the surrounding district should join Society No. 44 and work with the town people to make future exhibits worthy of the magnificent farming community in which it is located.

Woodstock Exhibition Prize Winners

HORSES

Standard Breds

Stallion, 4 years old—1, Earle B. Avery, Woodstock.

tSallion, 3 years old—1 and 2, J. W. Gallagher, Woodstock.

Filly, 4 years old—1, A. J. Saunders, Houlton, Me.; 2 and 3, J. W. Gallagher.

Filly, 2 years old—1, W. H. Lindsay, Woodstock Cor.; 2, A. J. Saunders; 3, Clover Nook Stock Farm.

Filly, 1 year old—1 and 2, A. J. Saunders.

Foal of 1919—1, J. W. Gallagher.

Brood Mare with Foal—1, J. W. Gallagher.

(Continued on page 874)

THE FREDERICTON EXHIBITION

After a lapse of four years in their exhibition activities, Agricultural Society No. 34, Fredericton, N. B., staged its 1919 fair on September 13th to the 20th. Twenty thuosand dollars were hung up for prizes with competition open to Canada and State of Maine.

W. S. Hooper, the genial, efficient secretary-manager of this popular fair in pre-war days, was again at the helm of affairs with several of the most prominent business men of the celestial city as his aides in charge of the various departments of the big show. The characteristic courtesy afforded ehibitors at Fredericton in bygone years—a courtesy that hsa always made the stock man yike to exhibit at Fredericton, was well maintained this year. The weather, although cool and rather lowering at times, throughout the major portion of the show period did not prevent the attendance of thousands of sight-seers who thronged from day to day through the turnstiles and on to the many interesting sections of the fair.

The clanging of the hammers of the workmen, who were putting the finishing touches on the booths in the main building, had not yet ceased to reverberate throughout the arches and corridors when on the evening of the 13th, Hon. J. F. Tweeddale, Minister of Agriculture, arose in his place in one of the side galleries to deliver the official opening address. He voiced his regrets at the inability of His Honor Lieutenant-Governor Pugsley and Hon. W. E. Foster, Premier of the Province, to be present owing to an engagemnt of importance re Valley Railway affairs with the officials of the Canadian National and Canadian Pacific Railways. Following are extractsh from Mr. Tweeddale's address:

Hon. Mr. Tweeddale, in opening the Ehibition, dealt with many of the same subjects that he discussed in his speech at Woodstock last week at the opening of the St. John Valley Fair. He repeated some of the announcements of policy in matters connected with the Agricultural Department's work in New Brunswick, which he had made at that time, and made a plea for production as the only method of reducing the present high cost of living and bringing about a satisfactory readjustment of the trade balance for Canada.

Because of the importance of the occasion, Hon. Mr. Tweeddale had prepared an address, which he read as follows:

"I am pleased to be here tonight, at this the opening of your Exhibition, and, as this is recognized as the Provincial Exhibition this year, it is disapponting that it has not been honored at its opening with an address from His Honor, the Lieutenant-Governor, and the Premier, and appropriate that the Minister presdiing over the Provincial Department of Agriculture be present.

"When we realize the fact that the agricultural products of Canada, according to statistics, have a greater monied value than have the combined products of our three other great natural resources—our forests, fisheries, and mines—the importance of agriculture will be appreciated.

"It seems to have been the decree of Divine Providence, in providing the forest growths and the teeming millions of the fishes of the sea, together with the products of the soil, for the use of man, that man must work and toil before he can avail himself of their benefits, so necessary for his comfort in fact, for the sustenance of his life. We ean see that this was a wise provision, as it compels energy industry, the exercise of our physical as well as mental and inventive powers, giving development to both mind and body, that elevates the human family to a higher standard of civilization than would obtain were these things to be gotten without exertion. But the products of the soil, which go more directly to the sustenance of life, differ from the products of our other natural resources. The minerals and metals, our forest growth, the food obtained from the oceans, already exist but the products of the soil are creative. The wheat and other grains, the corn, vegetables, cultivated fruits, do not exist they are only produced by intelligent cultivation, brought about by bringing into action the chemical qualities of the soil that create vegetable life, which cause a multiplied reproduction, the success of which is dependent upon climatic conditions, a well regulated supply of heat, light and moisture—elements altogether in the control of a benign Providence.

"These facts at once make us realize also how much more directly we are dependent on the farmer for our existence than those engaged in the other industrial pursuits of the country.

"It is not long since farming was looked upon as a menial occupation, but it is now being recognized as a business the success of which requires close and constant application, as well as knowledge gained by experience of how to cultivate the soil and manage the work. And, by reason of the world's demands and requirements for more foodstuffs, the old saying is more than ever true—that he who makes two blades of grass grow where only one grew before is a public benefactor.

"We have just emerged from the most destructive war known to civilization, to which Canada has contributed, both in blood and treasure, according to population, equally, if not greater than any of the Allied forces. The valor of our troops has materially contributed to the victory that has sustained the principles of liberty, justice, freedom, democracy and the constitution under which we live and are governed.

"The Canadian soldiers have assisted in sustaining British institutions and brought honor and glory to themselves and Canada. We see reactionary movements rising up in all of the countries overseas, as well as with our neighbors to the south of us, where life and property are being destroyed, and it is a splendid utterance coming from our returned soldiers' organizations in Canada, that they will not tolerate Bolshevism in this country.

"The great problem now confronting us is, to settle the spirit of unrest. To restore matters to normal conditions will tax the greatest minds of the age. Commissions are being appointed both in Canada and the United States to reduce the high cost of living—a procedure well taken to prevent excessive profits. Along with this,, we wtll next have the great problem of the liquidation of the tremendous war debt that Canada has assumed in the prosecution and as a consequence of the war.

"Both of these great problems are answered by the same remedy, and that is Production. We read in the public press and hear theories enumerated by public men as a remedy for those two great problems. But this should be the slogan of all governments, Imeprial, Federal, Provincial, Municipal and Civic, as well as every loyal citizen—Production, Production, Production.

"I don't think I am pessimistic when I say that at the present time, while money is plentiful, we are living in a period of false prosperity. Money is plentiful and we are glad it is so; we can't afford to stop until we are tided over this period of unrest. We cannot stop; we must carry on. The industrial life of the country must be kept going, even at a loss; but the money in circulation is largely from our mountry's borrowings, being expended in the legitimate expenses of the war and our apparent prosperity is of a kin to a man who has mortgaged his farm, ceases work and spends the proceeds freely, living in the enjoyment of the luxuries that money will buy; his obligation will some day have to be met.

"The most positive evidence of our position is seen in the fact that our money is discounted in the United States. The balance of trade is against us.

"I had a fear that the Americans would put an embargo against our potatoes going into their markets, but a survey of the potato production in the United Stateh has satisfied them that, on acocunt of failure in the large potato growing states, their supply will not be equal to their requirements and, in view of the high cost of living, it would not be wise to shut out our potatoes. The large amount of money coming in from the United States for our potatoes will assist in restoring the balance of trade."

After repeating the announcements as to wheat, sheep and fertilizer policies made at Woodstock, he said:

"'Your Exhibition has through the efficient management of your directors, together with the business methods of your secretary, aready established a reputation as one of the best provincial exhibitions, especially from the standpoint of an agricultural show. St. Stephen has put on a particularly good agricultural show; weather conditions have been against both Woodstock and St. Stephen; Chatham, coming after yours, will, no doubt, have a splendid exhibit, as the stock will go there from here to compete for their prizes.

"You are starting under very favorable prospects of the best weather, and I am sure the success of this first after-the-war provincial exhibition will be the best ever, from every point of view, and the thing we are mose proud of is the war is over and the Union Jack is flying at your masthead.

"I now declare this Exhibition formally open to the public."

The old transportation building, which was destroyed by fire while the buildings and grounds were under the supervision of the military authorities, has been replaced by a commodious new two story concrete-block building which housed on the ground floor the exhibits of dealers in the various popular automobiles that are offered for sale in the province—McLaughlin, Ford, Cole, Maxwell, Chalmers, Chevrolet, Gray Dort, Cadillac, Studebaker and Overland. Here too were the exhibits of the Renfrew Machinery Company — Standard Cream Separators and Engines. The De Laval Separator Company Separators, Gasoline Engines, Milking Machines and Electric Light equipment for farms. International Harvester Company's Manure Spreader and Tractors. Wallace Machine Works, Sussex, Little Giant Threshers and the Phelps Mfg. Company's Electric Light plant and other electrical equipment. The Cleveland Tractor was also there and cleverly manipulated, plowed and harrowed in the infield of the race track as well as hauled the brush harrow over the track between heats.

The second storey of the building housed the poultry show as well as the demonstration booths of the Poultry Division of the New Brunswick Departmen of Agriculture, the Dominion Poultry Branch, the Dominion Live Stock Division and the New Brunswick Forestry Division, all of which had features that appealed to the public.

The elimination of the poultry show from the annex of the main building left a splendid space for the display of the products of the field, farm and garden. This display, spread out over a wide area, did not appear as extensive as in other years. The competition was, however, quite keen and the quality exceptionally good.

The horticultural section of the show contained a good display of the abundance of fruit that the province boasts this year. To one side of this section was a bank of boxed apples of appetizing appearance, tastefully arranged around a circular bed of Golden Russet apples with a shield shaped Union Jack in the centre. Artistically spaced near the outer circle were placed some delicious looking crab apples to form the words FOR SERVICE AT THE FRONT. This display was deservingly admired and reflected a great deal of credit on Mr. Turney, the Provincial Horticulturist and his staff.

The products of the Apiary and accessories necessary for the management of bees in the modern way was displayed by L. T. Floyd, the Provincial Apiculturist, who was constantly on hand to furnish information to the throngs of interested visitors. The work Mr. Floyd is doing among the bee keepers of the province is bearing good results so that thousands of pounds of New Brunswick made honey will be marketed this year by men and women who have only recently taken up this industry under his guidance.

Every foot of available space in the main building was used and the tastefully arranged booths with their brilliant lights anl artistic signs made a particularly pleasing appearance.

The midway was a veritable hive of amusement, interest and fakirism. Objectionable features were eliminated as much as possible. It may be that a few wro tried to beat the fakirs at their own game, got stung occasionally, but then that's the public's lookout. The adage that "A fool and his money are easily parted," is as true in 1919 as it was in the years of long ago.

The exhibit of dairy products was quite extensive and of excellent quality.

The soldier's vocational school exhibit in the gallery of the main building was a veritable object lesson, illustrating the splendid work that is being done in the way of retaining the sickly and badly wounded in the crafts that will help them face the adverse conditions under which so many will ultimately have to face the problem of makiny a living for themselves and their dependents. Under the direction of skilled instructors the soldier boys are accomplishing wonderfully and cleverly wrought pieces of workmanship.

The Live Stock

The horse classes at Fredericton were not so keenly contested as they were in pre-war times. This is particularly true in regard to the light horse classes which have, owing to popularity of the automobile, come to the vicinity of the good-bye point.

In the Sandard Bred class for aged stallions H. C. Jewett's horses came in for first and second places with Mr. H. G. Kitchen's horse in third place. Hugh O'Neill, of Fredericton, showed a nice yearling stallion and several nice filllies.

Snowball's aged stallion alone represented the Hackney breed.

Roadsters and carriage horses were few in numbers and nothing much to brag about in point of quality.

Agricultural, general purpose and draft horses were also few in number but contained several horses of considerable merit.

In Cyldesdale Stallions over four years there were four entries, the placing being the same as at St. Ste-

phen, Snowball's Baron's Own at the head of the list with Jewett's Dr. McCoy in second place and Kelvin's Pride coming next. Clover Nook Stock Farm showed a nice young stallion of good quality, the get of Paron Squire. In the female sections Snowball fillies led the way.

J. R. Jewett, E. Allen, Alphonse Kelly, S. Illingworth and several others whose names appear in the list of prize winners were, next to the breeders already mentioned, the principal contributors to the horse show.

Cattle

The big event in the beef cattle show was the Shorthorn class, where R. A. Snowball's and J. M. Laird's herds clashed. These were the two principal contestants. J. R. Jewett had several young animals of good quality, but not in the show shape of the individuals from the other herds.

In aged bulls the Lairds' led the way with White Gloucester, a massive white bull of missie strain, a recent acquisition to head the Evergreen farm herd. Stately Monarch, an erstwhile unbeaten champion as head of the Snowball herd and formerly at the head of the Laird and Griffin herds, went down to second place. It was tit for tat throughout the remaining sections of the class as will be seen by the list of awards. The female classes, according to Judge John Guardhouse, were a good, useful aggregation that would stand a lot of competition at some of the larger shows.

Horne Bros., of Prince Edward Island met no competition with their Polled Angus cattle and had a walk over with their splendidly fitted herd.

Ayrshire cattle were shown by McIntyre Bros., John Retson, Clover Nook Stock Farm and Mr. Paisley. McIntyre Bros and Retson captured the major portion of the money with their well fitted herds.

In Holsteins Dickie Bros., Harding Bros. and Clover Nook Stock Farm competed for the honors, the major jortion of the choicest plums going to to the Truro and Welsford herds.

Jerseys were shown by J. R. Semper & Son, of Truro, who had everything practically all their own way.

Libby herds of Brown Swiss cattle from the province of Quebec that showed at Woodstock during the previous week were also shown in the capital city fair.

Sheep

The keenest competition in any section of the show was on in the sheep classes, where New Brunswick, Nova Scotia, Prince Edward Island, Quebec and Ontario flocks were out in the pink of condition. The competition was particularly keen in the Shrop, Oxford, Horned Dorset and Cheviot classes, where there was a fight to the finish in nearly every section. No one could stand by the ring while without experiencing a high degree of pleasure from the well fitted, typical individual pairs and quartettes that were led out to be judged. When it comes to selecting, fitting and showing sheep one must take off his hat to some of our Maritime Province breeders who have in their flocks as good individuals as one can find anywhere in Canada.

Swine

The swine show was particularly good. One of the main features of the exceptionally good showing made by the young boys who are members of the Boys Pig Clubs conducted under the auspices of the New Brunswick Department of Agriculture. In the Yorkshire and Chester classes the boys made the older exhibitors step lively, capturing the coveted red and blue ribbons in the various sections in which they had entries..

Waldo Walsh, the Assistant Live Stock Superintendent for the province who has been putting forth his best efforts among the boys during the past year, was wearing the smile that is so characteristic of him, when at the conclusion of the judging his boys were found in the first ranks.

There was a lively contest in the Berkshire class between J. B. Semple's herd and that of Shaw Bros., of Victoria, N. B.

The poultry show was somewhat slimmer than usual, the breeders claim the revised prize list in their classes do not give sufficient encouragement to make large exhibits.

The modern brooder house and the colony house shown by the New Brunswick Department of Agriculture with their equipment and tit bits of advice in poultry lores were appreciatingly noted by the visitors.

The judges of the various classes were as follows:

Light Horses.—Alex. Ness, McDonald College, Quebec.

Heavy Horses.—Adam Scharf, Cummings Bridge, Ont.

Beef Cattle.—John Guardhouse, Weston, Ontario.

Dairy Cattle.—Wm. Ballantyne, Stratford, Ontario.

Swine.—P. J. McEwen, Wyoming, Ontario

Sheep.—John Guardhouse, Weston, Ontario.

Poultry.—John Clark, Cainsville, Ontario.

Honey.—L. T. Floyd, Sussex.

Agricultural Products.—S. J. Moore, Truro, N. S.

Dairy Products.—Harvey Mitchell, Keswick; James Burgess, Ottawa and W. A. McKay, Truro, N. S.

Fruit.—A .G. Turney, Fredericton.

Live stock being the king pin of successful agriculture in Maritime Canada we look forward to rapid development along this line. Good stock of high individual and ancestral merit well advertised, may be sold at remunerative prices. Exhibitions afford a splendid advertising medium and it behooves our breeders to get busy and prepare for future events at Fredericton.

PRIZE WINNERS AT FREDERICTON EXHIBITION

STANDARD BRED HORSES

Stallion 4 years old.—1st, H. C. Jewett, Fredericton 2nd, H. C. Jewett; 3rd, H. G. Kitchen, Fredericton.

Stallion 1 year old.—1st, H. G. O'Neill, Fredericton.

Filly 4 years old.—1st, Hugh O'Neill

Filly 3 years old.—1st, Hugh O'Neill

Filly 2 years old.—1st, Hugh O'Neill 2nd, Clovernook Stock Farm, Hartland, N. B.

Foal of 1919.—1st, H. G. Kitchen.

Brood Mare with Foal.—1st, H. G. Kitchen.

Hackneys

Stallion 4 years old.—1st, R. A. Snowball, Chatham, N. B.

Heavy Draft Horses

Brood aMre, any age.—1st, Elwood Allan; 2nd, John R. Jewett, Island View, N. B.

Filly or Gelding 4 years old.—1st, Alphonso Kelly, Fredericton.

Filly or Gelding 3 years old.—1st, John R. Jewett.

Foal of 1919.—1st, John R. Jewett; 2nd, Elwood Allan; 3rd, Emery Ketch.

Clydesdales

Stallion 4 years old.—1st and 3rd, R. A. Snowball; 2nd, H. C. Jewett.

Stallion 3 years old.—1st Clover Noop Stock Farm.

Filly 4 years old.—1st, R. A. Snowball.

Clydesdale oHrses—Special

Stallion.—st, R. A. Snowball.

Female.—1st, R. A. Snowball.

Single Grade Mare—1st, R.A. Snowball.

Specials

Foals of 1919, the get of H. C. Jewett's Percheron stallion Hussard.—1st, Emery Ketch; 2nd, Bertrand Goodspped; 3rd, W. Illingworth.

Foals of 1919, gat of Cyldesdale Stallion, Day Dream.—1st, John R. Jewett, 2nd, Alphonso Kelly.

General Purpose Horse

Mare or Gelding, any age.—1st, John Jackson, St .John; 2nd, Bertrand Goodspeed.

Matched Team in Harness.—1st, John R. Jewett; 2nd, W. Illingworth.

Agricultural Horses

Brood Mare.—1st, Hedley Aiken; 2nd, Alphonso Kelly; 3rd, Emery Ketch.

Filly or Gelding, 4 years old.—1st, R. A. Snowball; pnd, Alphonso Kelly; 3rd, W. A. McVey.

Filly or Gelding, 1 year old.—1st, R. A. Snowball; 2nd, Alphonso Kelly.

Foal of 1919.—1st. Alphonso Kelly.

Span (Geldings or aMres).—1st, Alphonso Kelly.

Horses

Saddle Horse ridden by a Gentleman.—1st, R. W. Carson, St. John; 2nd, John Jackson, St. John.

Saddle Horse ridden by a Lady.—1st, Miss Eileen Keenan, Fredericton; 2nd, R. W. Carson.

Carriage Horses

Carriage Torse.—1st, H. C. Jewett; 2nd, H. G. Kitchen; 3rd, R. W. Carson.

Matched Pair.—3rd, ohn R. Jewett.

Horse driven by Lady.—1st, R. W. Carson; 2nd, Mrs. L. G. Richards; 3rd, Mrs. Lee Haining.

Roadsters

1st, Hugh O'Neill; 2nd, Nehemiah Keirstead; 3rd, Miss Eileen Keenan.

Driven by a Lady.—1st, Hugh O'Neill; 2nd, Miss Eileen Keenan.

Pony in Single Harness.—1st, W. D. Gunter, Fredericton.

CATTLE

Shorthorns

Bull 3 years old and upwards.—1st, J. M. Laird & Sons, Kelvin Grove, P. E. I.; 2nd, R. A. Snowball; 3rd, John R. Jewett.

Bull, Senior.—1st, Burpee & Smith, Nashwaaksis, N. B.

Bull, uJnior.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball; 3rd, John R. Jewett; 4th, John R. Jewett.

Bull Calf, over 6 months.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball.

Bull Calf, under 6 months.—1st, R. A. Snowball; 2nd, R. A. Snowball; 3rd, J. M. Laird & Sons.

Cow, 4 years old and upwards.—1st, R. A. Snowball; 2nd, J. M. Laird & Sons; 3rd, R. A. Snowball; 4th, J. M. Laird & Sons.

Cow, 3 years old.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball.

Cow or Heifer, 2 years—1st, R. A. Snowball; 2nd, J M. Laird & Sons.

Heifer, Senior Yearling.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball.

Heifer, Junior Yearling.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball.

Heifer and Calf, under 12 months and over 6.—1st, R. A. Snowball; 2nd, J. M. Laird & Sons; 3rd, J. M. Laird & Sons.

Heifer Calf, under 6 months.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball; 3rd, R. A. Snowball.

Aged Herd.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball.

Breeder's Young Herd.—1st. J. M. Laird & Sons;2nd, R. A. Snowball.

Bull and 3 of his get.—1st, John R. Jewett.

Cow and 2 of her get.—1st, J. M. Laird & Sons; 2nd, R. A. Snowball; 3rd, J. M. Laird & Sons.

Female, any age.—Diploma, R. A. Snowball.

Polled Angus Cattle

Bull, 3 years old.—1st, Horne Bros., Winsloe Station, P.E.I.

Bull, 2 years old.—1st. Horne Bros.

Bull calf, over 6 mos.—1st, Horne Bros.

Bull Calf, under 6 mos.—1st, Horne Bros.; 2nd, Horne Bros.

Cow, 4 years old and upwards.—1st, Horne Bros.; 2nd, Horne Bros.

Cow, 3 years old.—1st, Horne Bros.; 2nd, Horne Bros.

Cow or Heifer, 2 years old.—1st, Horne Bros.; 2nd, Horne Bros.

Heifer, Senior Yearling.—1st, Horne Bros.

Heifer, Junior Yearling.—1st, Horne Bros.; 2nd, Horne Bros.

Heifer Calf, senior.—1st, Horne Bros.

Heifer Calf, under 6 months.—1st, Horen Bros.

Aged Herd.—1st, Horne Bros.

Breeders' Young Herd.—1st, Horne Bros.

Bull and 3 of his get.—Diploma, Horne Bros.

Cow and 3 of her offspring.—Diploma, Horne Bros.

Cow and 2 of her ogspring.—Diploma, Horne Bros.

Bull, any age.—Diploma, Horne Bros.

Female, any age.—Diploma, Horne Bros.

Beef Grades

Cow, 4 years old.—1st, R. A. Snowball; 2nd, J. M. Laird & Sons.

Cow, 2 years old.—1st, J. M. Laird & Sons.

Heifer, 1 year old.—1st. J. M. Laird & Sons.

Fat Cattle

Fat Cow or Heifer.—1st, J. M. Laird & Sons.

Pair Fat Cattle.—1st, J. M. Laird & Sons.

Ayrshires

Bull, 3 years old and upwards.—1st, McIntyre Bros., Sussex.

Bull, 2 years old.—1st, McIntyre Bros.;2nd, Clovernook Stock Farm, Hartland, N. B.

Bul, senior, 18 mos. and under 24.—1st, McIntyre Bros.

Bull, junior, 12 mos. and under 18 mos.—1st, McIntyre Bros; 2nd, John Retson, Truro, N. S.

Bull Calf, over 6 months.—1st, John Retson; 2nd, McIntyre Bros.; 3rd, Jas. K. Paisley, Beaver Brook, N. B.

Bull Calf, under 6 months.—1st, McIntyre Bros.; 2nd, James K. Paisley.

Cow, 4 years old and upwards.—1st, McIntyre Bros.; 2nd, John Retson; 3rd, McIntyre Bros.

Dry Cow, 4 years old and upwards.—1st, McIntyre Bros.; 2nd, John Retson; 3rd, McIntyre Bros.

Cow, 3 years old.—1st, McIntyre Bros.; 2nd, McIntyre Bros.; 3rd, Jas. K. Paisley.

Dry Cow, 3 years old.—1st.—McIntyre Bros.; 2nd, McIntyre Bros.

Cow, 2 years old.—1st, John Retson; 2nd, McIntyre Bros.; 3rd, McIntyre Bros.

Heifer, senior yearling.—1st, McIntyre Bros.; 2nd, McIntyre Bros; 3rd, James K. Paisley.

Heifer, junior yearling.—1st, McIntyre Bros.; 2nd, McIntyre Bros.; 3rd, James K. Paisley.

Heifer Calf, senior.—1st, John Retson; 2nd. McIntyre Bros.; 3rd, James K. Paisley; 4th, McIntyre Bros.

Heifer Calf, junior.—1st, McIntyre Bros.; 2nd, McIntyre Bros.; 3rd, Jas. K. Paisley.

Aged Herd.—1st, McIntyre Bros.; 2nd, McIntyre Bros.; 3rd, John Retson

Breeders' oYung Herd.—1st, McIntyre Bros.; 2nd. McIntyre Bros.; 3rd, James K. Paisley.

ST. JOHN VALLEY EXHIBITION

(Continued from page 871)

Stallion, any age—1, J. W. Gallagher.

Mare, any age—1, J. W. Gallagher.

Stallion and three of his get—1, J. W. Gallagher.

Clydesdale Horses

Stallion, 4 years old—1, L. B. McElhinney, Woodstock.

Stallion, 2 years old—1, Clover Nook Stock Farm.

Stallion, 1 year old—1, Clover Nook Stock Farm; 2, Harry Reid, Woodstock.

Filly, 4 years old—1, Earle B. Avery; 2 and 3, Clover Nook Stock Farm.

Filly, 2 years old—1, Clover Nook Stock Farm.

Champion Mare—Earl B. Avery.

Stallion, and three of his get—L. B. McElhinney.

Percherons

Stallion, 4 years old—1, C. E. Allen, Hartland; 2, Geo. H. Benn, Hodgen, Me.

Stallion, 3 years old—1, Geo. H. Benn.

Stallion, 2 years old—1, Warren C. Bull, Woodstock.

Stallion, 1 year old—1, Geo. H. Benn.

Mare, 4 years old—1, Chas. Gray, Upper Woodstock.

Mare, 2 years old—1, Chas. Gray.

Driving Horses

Mare or Gelding—1, J. J. Hale, Grafton; 2, Chas. P. Palmer, Woodstock; 3, W. H. Lindsay.

General Purpose Horses

Mare or Gelding, any age, shown in harness—1, Chas. P. Palmer; 2, W. H. Lindsay; 3, Warren C. Bull.

Matched Team, shown in harness—1, Howard Palmer, Woodstock.

Agricultural Horses

Brood Mare with Foal—1, L. D. McElhinney; 2, Chas. Monteith, Northampton, N. B.; 3, Carey Dickinson, Simmonds.

Filly or Gelding, 4 years old—1, Carey Dickinson; 2, Warren Bull.

Filly or Gelding, 3 years old—1, Warren Bull.

Filly or Gelding, 2 years old—1, Judson Rideout, Hartland; 2, W. H. Lindsay; 3, Chas. P. Palmer.

Filly, 1 year old—1, Chas. P. Palmer & Sons; 2, Judson Rideout, Hartland.

Foal of 1919—1, Chas. Monteith; 2, Carey Dickinson; 3, Benj. Wilson, Hartford, N. B.

Matched Team in harness—1, Edmund Dickinson, Debec Jct.; 2, Howard Palmer; 3, W. H. Rogers, Woodstock.

Heavy Draft Horses

Brood Mare with foal—1, Chas. Monteith.

Filly or Gelding, 4 years old—1, Chas. P. Palmer & Son; 2, Warren Bull.

Filly or Gelding, 3 years old—1, Warren Bull.

Filly or Gelding, 2 years old—1, W. H. Lindsay.

Foal of 1919—1, Chas. Montieth.

Matched Team—1, Edmund Dickinson, Debec; 2, W. C. Hall, Grafton.

CATTLE

Shorthorns

Bull, 3 years old—1, J. M. Laird & Son, Kelvin Grove, P. E. I.; 2, W. L. Carr, Woodstock.

Bull, 2 years old—1, Chas. P. Palmer, Woodstock; 2, A. J. Raymond, Woodstock.

Bull, junior yearling—1, J. M. Laird & Son; 2, J. H. Millbury, Woodstock; 3, Harry Reid, Woodstock.

Bull, senior calf—1, J. M. Laird & Son; 2, H. C. Cochrane, Victoria, N. B.; 3, F. M. Slipp, Woodstock.

Bull, junior calf—1, J. M. Laird & Son.

Cow, 4 years old and upwards—1 and 2, J. M. Laird & Son; 3, F. B. Carvell, Woodstock.

Cow, 3 years old—1, J. M. Laird & Son; 2 and 3, F. B. Carvell.

Cow or Heifer, 2 years old—1, J. M. Laird & Son; 2 and 3, F. M. Slipp.

Heifer, senior yearling—1, J. M. Laird & Son; 2, Chas. P. Palmer & Sons; 3, F. B. Carvell.

Heifer, junior yearling—1, J. M. Laird & Son.

Heifer, senior calf—1 and 2, J. M. Laird & Son.

Heifer, junior calf—1, J. M. Laird & Son; 2, F. B. Carvell.

Aged herd—1, J. M. Laird & Son.

Breeders' Young Herd—1, J. M. Laird & Son.

Cow and two of her offspring—1 and 2, J. M. Laird & Son; 3, Charles Palmer & Son.

Bull, any age—1, J. M. Laird & Son.

Female, any age—1, J. M. Laird & Son.

Polled Angus

Bull, 3 years old and upwards—1, Horne Bros., Winsloe Sta., P. E. I.

Bull, junior yearling—1, Horne Bros.

Bull, senior calf—1, Horne Bros.

Bull, junior calf—1 and 2, Horne Bros.

Cow, 4 years old—1 and 2, Horne Bros.

Cow, 3 years old—1 and 2, Horne Bros.

Cow or Heifer, 2 years old—1 and 2, Horne Bros.

Heifer, senior yearling—Horne Bros.

Heifer, junior yearling—1 and 2, Horne Bros.

Heifer, senior calf—Horne Bros.

Heifer, junior calf—Horne Bros

Aged Herd—Horne Bros.

Breeders' Young Herd—Horne Bros.

Bull and three of his get—1, Horne Bros.

Cow and two of her offspring—1. Horne Bros.

Bull, any age—1, Horne Bros.

Female, any age—1, Horne Bros.

Ayrshires

Bull, 3 years old and upwards—1, McIntyre Bros., Sussex, N. B.

Bull, 2 years old—1, McIntyre Bros.; 2, Clover Nook Farm, Hartland.

Bull, senior yearling—1, McIntyre Bros.

Bull, junior yearling—1, McIntyre Bros.; 2, John Retson, Truro, N. S.; 3, H. W. Rogers, Woodstock.

Bull, senior calf—1, John Retson; 2, McIntyre Bros.

Bull, junior calf—1, McIntyre Bros.

Cow, 4 years old—1, McIntyre Bros.; 2, John Retson; 3, Clover Nook Stock Farm.

Dry Cow, 4 years old—1 and 3, McIntyre Bros.; 2 and 4, John Retson.

Cow, 3 years old—1 and 2, McIntyre Bros.; 3, Clover Nook Stock Farm.

Dry Cow, 3 years old—1, McIntyre Bros.

Cow, 2 years old—1, John Retson; 2 and 3, McIntyre Bros.

Heifer, senior yearling—1 and 2, McIntyre Bros.

Heifer, junior yearling—1 and 2, McIntyre Bros.

Heifer, senior calf—1 and 2, McIntyre Bros.; 3, Clover Nook Stock Farm.

Heifer, junior calf—1 and 2, McIntyre Bros.; 3, Clover Nook Stock Farm.

Aged herd—1 and 3—McIntyre Bros.; 2, John Retson.

Breeders' young herd—1 and 2, McIntyre Bros.

Four animals get of one sire—1, 2 and 3, McIntyre Bros.

Two animals, progeny of one cow—1 and 3, McIntyre Bros.; 2, John Retson .

Bull and 3 of his get—1, McIntyre Bros.

Cow and 2 of her offspring—1, John Retson; 2, McIntyre Bros.

Holsteins

Bull, 2 years old—1, Clover Nook Stock Farm; 2, John W. Purvis, Woodstock; 3, W. H. Lindsay, Woodstock.

Bull, junior yearling—1, Earle B. Avery, Woodstock; 2, Clover Nook Stock Farm; 3, W. Carr.

Bull, senior calf—1, Clover Nook Stock Farm.

Bull, junior calf—1, John W. Purvis.

Cow, 4 years old—1 and 4, Clover Nook Stock Farm; 2, Earle B. Avery; 3, Warren C. Bull.

Dry Cow, 4 years old—1, Warren C. Bull; 2, Clover Nook Stock Farm.

Cow, 2 years old—1, F. K. Brown, Upper Brighton; 2, W. H. Lindsay.

Heifer, senior yearling—1, Clover Nook Stock Farm; 2 and 3, W. C. Hall.

Heifer, junior yearling—1, Clover Nook Stock Farm; 2, Warren C. Bull; 3, F. K. Brown.

Heifer, senior calf—1, Clover Nook Stock Farm; 2 and 3, Warren C. Bull.

Heifer, senior calf—1, Clover Nook Stock Farm; 2 and 3, Warren C. Bull.

Heifer, junior calf—1, W. H. Lindsay; 2 and 3, John W. Purvis. '

Aged herd—1, Clover Nook Stock Farm.

Breeders' young herd—1, Clover Nook Stock Farm; 4, Warren C. Bull.

Four calves, bred by exhibitor—1, John W. Purvis; 2, Clover Nook Stock Farm.

Three animals, get of one sire—1, John W. Purves; 2, Clover Nook Stock Farm.

Three animals, progeny of cow—1, Clover Nook Stock Farm.

Bull and three of his get—1, John W. Purves.

Jerseys

Bull, 3 years old—1, J. R. Semple & Son, Truro, N. S.

Bull, junior calf—1, J. R. Semple & Son.

Cow, 4 years old—1, A. J. Raymond.

Cow, 2 years old—1, J. R. Semple & Son; 2, A. J. Raymond.

Heifer, senior yearling—1, J. R. Semple & Son.

Heifer, senior calf—1, 2 and 3, J. R. Semple & Son.

Breeders' young herd—1, J. R. Semple & Son.

Bull and three of his get—1, J. Semple & Son.

Guernseys

Bull, 3 years old—1, Geo. H. Benn, Hodgden, Me.

Bull, senior calf—1, Geo. H. Benn.

Cow, 4 years old—1, Geo. H. Benn.

Dry Cow, 4 years old—1, Geo. H. Benn.

Cow, 3 years old—1, Geo. H. Benn.

Dry Cow, 3 years old—1, Geo. H. Benn.

Cow, 2 years old—1, 2 and 3, Geo. H. Benn.

Heifer, senior yearling—1, Geo. H. Benn.

Heifer, junior yearling—1, Geo. H. Benn.

Heifer, senior calf—1 and 2, Geo. H. Benn.

Heifer, junior calf—1, Geo. H. Benn.

Aged herd—1, Geo. H. Benn.

Breeders' young herd—1, Geo. H. Benn.

Bull and 3 of his get—1, Geo. H. Benn.

Cow and two of her offspring—1, Geo. H. Benn.

Brown Swiss

Bull, 3 years old—1, Ralph H. Libby, Stanstead, Que.; 2 and 3, W. A. Jolley, Waterloo, Que.

Bull, 2 years old—1, Ralph H. Libby.

Bull, senior yearling—1, W. A. Jolley; 2, Ralph H. Libby.

Bull, junior yearling—1, W. A. Jolley.

Bull, senior calf—1, W. A. Jolley; 2, Ralph H. Libby.

Bull, junior calf—1, W. A. Jolley; 2, Ralph H. Libbey.

Cow, 4 years old—1 and 2, Ralph H. Libbey; 3, W. A. Jolley.

Dry Cow, 4 years old—1, Ralph W. Libbey.

Cow, 3 years old—1, W. A. Jolley; 2, Ralph H. Libbey.

Cow, 2 years old—1 and 3, Ralph H. Libbey; 2, W. A. Jolley.

Heifer, senior yearling—1, W. A. Jolley.

Heifer, junior yearling—1 and 3, Ralph H. Libbey; 2, W. A. Jolley.

Heifer, senior calf—1, Ralph H. Libbey.

Heifer, junior calf—1 and 2, W. A. Jolley; 3, Ralph H. Libbey.

Aged herd—1, Ralph H. Libbey; 2, W. A. Jolley.

Breeders' young herd—1, W. A. Jolley; 2, Ralph H. Libbey.

Bull and 3 of his get—1, Ralph H. Libbey; 2, W. A. Jolley.

Cow and 2 of her offspring—1, Ralph H. Libbey; 2, W. A. Jolley.

Dairy Grades

Dry Cow, 4 years old—1 and 2, W. Carr, Woodstock.

Heifer, junior yearling—1, F. K. Brown.

Heifer, senior calf—1, Warren C. Bull.

Heifer, junior calf—1, W. Carr; 2, Chas. P. Bull, Northampton.

Cow, 4 years old—1 and 3, W. Carr; 2, W. C. Hall.

Cow, 3 years old—1, W. Carr.

Cow, 2 years old—1, W. Carr.

Heifer, 2 years old—1, W. Carr; 2, W. C. Hall.

Beef Grades

Cow, 4 years old—1, J. M. Laird & Son.

Heifer, 2 years old—1, J. M. Laird & Son.

Heifer, 1 year old—1, J. M. Laird & Son.

Fat Cow, over 2 years—1, J. M. Laird & Son.

Pair Fat Cattle—1, J. M. Laird & Son.

SWINE

Berkshire

Boar, over 2 years—1, Shaw Bros., Hartland.

Boar, over 1 yr., under 2 yrs.—1, Shaw Bros.; 2, J. R. Semple & Son, Truro, N. S.

Boar, over 6 months, under 1 yr.—1, J. R. Semple & Son.

Boar, under 6 months—1 and 3, J. R. Semple & Son; 2, Shaw Bros.

Sow, over 2 yrs.—1, 2 and 3, J. R. Semple & Son.

Sow over 1 yr., under 2 yrs.—1, Shaw Bros.; 2, J. R. Semple & Son.

Sow, under 6 months—1 and 2, J. R. Semple & Son.

Breeding Sow with litter—1, J. R. Semple & Son; 2, Shaw Bros.

Herd, Boar and 3 females, any age—1 and 2, J. R. Semple & Son; 3, Shaw Bros.

Yorkshire

Sow, over 1 year—1, Glen Campbell, Arthurette, N. B.

BOYS PIG CLUB SHOW AT WOODSTOCK

Woodstock Exhibition saw something new in the swine classes in the form of exhibits from the "Boys Pig Clubs" of N. B.

These clubs, of which there are now 21, are comprised of at least 10 boys between the ages of 12 and 18 years, who are each supplied with a pure bred sow, 6 weeks old, which they are to keep 2 years and breed to a boar of the same breed, which is also supplied. The organization of the clubs and the purchase of the stock is done by the N. B. Dept. of Agriculture, while this purchase is financed by public spirited men, who are interested in the live stock industry and in the "coming stockmen." The foundation stock has been carefully selected from the leading swine breeders in the Maritime Provinces and Ontario, so that their offspring is the very best.

By a request of the Live Stock Division of the Dept. of Agriculture, the leading exhibitions in N. B. offered special classes in swine, open only to members of these clubs, and it was gratifying to see that the boys took advantage of this in sending pigs to the Woodstock Exhibition.

These pigs were in many cases entered in the open classes, and when this was done, they carried off the first and second prizes.

This goes to show that the stock was good and that the boys had them in good condition, and that the stock from these clubs should play an important part in the future of the pure bred swine industry of the province.

Announcing
A TRIUMPH

1920 McLaughlin Master Six now ready

Victorious Roman Chariot 50B.C.

Canada's Standard Car 1920

LEADERSHIP was ever accorded the victor

Supremacy is the reward of exceptional merit in all walks of life

Canada's Standard Car owes its leadership to its inherent merit

For 1920 the new McLaughlin Master Six more than ever maintains that reputation which has established its Supremacy from coast to coast.

See the new Master Six at the nearest McLaughlin Show Rooms or at the Canadian National Exhibition.

Gleanings From the N. S. Agricultural College

AGRICULTURAL SHOWS

The explosion at Halifax wiped out the possiblity of a Provnicial exhibtion by demolishing the buildings. To offset this there is an unusual number of County sows, and so far there is more than the usual interest taken in them. There have been or will be exhibition at the following points this Autumn—Caledonia, Bridegwater, Little Brook, Digby Shubenacadie, Musquodobit, Oxford, Antigonish, Guysborough, Inverness, Sydney and the Maritime Winter Fair at Amherst,

The distribution of these shows makes it possible for the farming population ol the Province to take in one or more during the season. The agricultural exhibition, with all its varied side lines along the lines of Domestic Science, etc., is an institution which should be patronized by every lover of home and country. It is one of the great means of advancement, through the dissemination of the most expert knowledge, and the demonstration of the best types of stock, vegetables, grains, etc. Besides, those who attend these will have an opportunity of meeting a representative of the Department of Agriculture, with benefit to both. It is a gratifying fact that Exhibitions throughout Canada this year have a record attendance.

DAIRY NOTES

The Co-operativeCreamery idea is taking hold and spreading into new communities. Two companies have recently been organized in Hants Co. one, known as the Avon Creamery, Ltd., embracing East Walton, Walton, Kempt, Burlington, and adjoining communities; the other, the East Hants Creamery Co., covering the Gore, Rawdon, Pleasant Valley, Nine Mile River, Kennetcook River and adpacent districts. Both organizations have made a good start, with an authorized capitailization of $10,000 each. The whole movement is largely due to the efforts of the Dairy Division, Nova Scotia Department of Agriculture, which was represented at the various meetings held by the Superintendent of this department, Mr. W. A. McKay.

The record made by Nova Scotia Creamery men at the Toronto Exhibition, Canada's Nationl Fair, is one to be proud of. Last year's showing was quite creditable, but this year's was better. There were four classes of entries, and from forty to fifty entries in each class. The highest score made in the exhibition was 97.50. Brookville Creamery came within the smallest possible fraction of this record with a score of 97.49 for unsalted butter, taking first place in this exhibit. Brookfield also stood high in other classes.

The Pictou County Dairy Co., at Stellarton, and the, Antigonish Dairy Co., at Antigonish, were both well up in the prize list while the Scotsburn Creamery and the La Have did not score so high, they had fine exhibits, and made a creditable sowing.

The results of this competition, entered on fair terms with dairy producers and products from all over Canada, should be encouraging to the farming interests of the East, and should stimulate dairy production in Nova Scotia. It has been demonstrated that this Province can compete with the world in the quality of her dairy products and that she can enter the markets with the best, confident of holding her own and of commanding the highest prices.

The standard obtained by the N. S. Creamery men, who have received their training at our own instiution in Truro, should convince young farmers who are ambitious to excel in this line that there is no better place to learn how than the N. S. Agricultural College. Drop a card to the Principal and get prospectus.

WOMEN'S INSTITUTES

The new Superintendent of Women's Institutes for Nova Scotia, Miss Helen Macdougall, has entered upon her duties, with headquarters at the Agricultural College, Truro. Miss Macdougall comes well prepared by training and experience. She took the regular course at the Provincial Training school under Miss McCall, and studied subsequently at Columbia University, New York. After several years of teaching in her chosen subject, she was appointed Supervisor of Home Economics for the Province of Manitoba. She now returns to her native Province to continue much the same line of work.

"For Home and Country" is the motto of this fine organization, and its activities are as varied, its ideals as high as the motto suggests. It has proven so effective an organization in the Old Country that 1,000 societies were started in England alone during the war. In this country our women's war activities were largely carried on under other names, Red Cross, Patriotic Leagues, etc., and it was thought best not to push the Institute organizatio nas such until th estrain of war should be over.

Happily the time has now arrived when women are disbanded very largely from these specific war activities, and the time is ripe for a big expansion along Institute lines. The great problems, some of them old and some new, which are more in evidence now than ever, are, for the most part beyond the reach of legislation. They lie too near to the very heart of our life to be dealt with by law. There can be no question that those fundamental institutions in which women have traditional and undisputed rights and powers, such as the home and the public school, are the spheres in which most can be done to mould our national iedals.

All this constitutes a call to women to rally to such an organiation as the Women's Institute. In this Province there are, at present, some fifty Institutes. A large number of districts are contemplating the formation of societies. The Annual meeting has been postponed from June until October so that the new Superintendent could be present. Any community which is thinking of organizing would do well to correspond wth Miss Macdougall at an early date, so that a representative may be sent to assist.

A GOOD OFFER TO SHEEP BREEDERS

The Live Stock Branch, Dominion Dept. of Agriculture, has recently issued a pamphlet, known as No. 19, giving information of a new policy for the encouragement of sheep breeding. To put it in a word—on application to this Branch any farmer who has never before used a pure bred ram, and who will undertake to secure one for the current year, will be paid a bonus of $10.00 in two instalments. This is a fine opportunity for farmers to improve their flocks, and many should take advantage of so generous an offer. The pamphlet, giving full information, may be had from the Live Stock Branch at Ottawa, or from the College at Truro .

FALL PLOWING

We have, at various times, advocated different measures to help overcome the shortage in mill feeds which have prevailed for three years past. Among these the improvement of pastures so as to ensure high production in milk and beef during the summer months is very important. The silo for winter feeding is also a big factor; but there is really nothing to take the place of grain feeds.

It must be borne in mind that we have looked and looked in vain for improvement in the feed situaton year by year, and that the outlook for the present year is even less promising than at any previous time, and prices have reached the highest level yet attained. There is little probability of any marked relief for at least a year or two yet.

In view of this situation there is one evident measure to be taken by every farmer, and now is the time to set about it, i. e., to plow for a large grain crop next year.

Fall plowing on nearly all farms in Nova Scotia has proven much better than Spring plowing for the growing of practically all kinds of crops. In some seasons it is impossible to get much done owing to the hard condition of the soil. The unusually heavy rain fall has removed this difficulty, and much of our soil is in good condition for plowing. Everything; therefore, points to the wisdom of keeping the plow going at every opportunity from this time until the winter frosts.

POLICIES ADOPTED FOR ENCOURAGEMENT OF SHEEP-RAISING

New Brunswick Department Makes an Important Announcement in this Regard—Supplements Dominion Bonus on Pure Bred Rams

The Province of New Brunswick is especially adapted for sheep-raising and the Department of Agriculture are putting forth every effort to encourage the extension of this industry. While it is highly desirable to have many more sheep in the Province, it is also of importance to work toward improving the quality of the breeding stock, so that a superior class of sheep will be raised.

Plans of a very practical nature have been decided upon to encourage both pure-bred breeders and breeders of grade stock within the province. In order to encourage the man who has never before used a pure-bred ram to purchase one this fall, the Department are supplementing the ten dollar premium offered by the Dominion Live Stock Branch to the extent of Five Dollars, this amount payable as soon as the ram is purchased and evidence submitted that a pure-bred ram has been purchased. Through this cooperation with the Dominion Live Stock Branch, it is expected that many farmers will be induced to purchase a pure-bred ram for the first time. The Fifteen Dollars received as a premium will bring the price down more nearly to the level of that of a grade. Under these circumstances, there will be every inducement for a man to purchase a pure-bred.

Another policy decided upon, embodying a plan which has never been attempted by any Province in Canada, is the grading of all the pure-bred rams offered for sale in the Province. The services of an outside man will be secured. This person will be a qualified sheep judge, who will visit each pure-bred breeder in the Province and classify the rams for sale into three grades—Superior, Average and Common. These rams will be marked acocrding to their grade. A farmer can write to a breeder for any grade that he desires and be sure of getting a ram up to the standard of that particular grade. The number for sale in the different grades, together with the price that the breeder is asking for each, will be listed with the Department at Fredericton. Information can thus be furnished to anyone wishing to make a purchase where he can secure a ram of the breed and grade required. This purchase can be made by mail practically as satisfactorily as by a personal visit.

The pure-bred breeder will get a cash premium of three dollars for each three star ram and two dollars for each two star ram produced. No premium will be given for the one star or common ram. This cash premium is expected to encourage better breeding methods on the part of pure-bred men and will be an incentive for them to pay a higher price and secure a better ram to head their flocks, in order that they may get as many of their rams in the higher grades as possible.

Boys' and Girls' Sheep Clubs are also being organized. Arrangements have been made through the Bankers' Association so that any Bank in the Province will provide credit to bona fide members of the Provincial Clubs. Two grade Shearling ewes will be the number allotted to each member. They can get twelve months' credit at six per cest interest at the Banks. The Department will supply a pure-b red ram to any Club with ten or more members. The ewes will be bred before being distributed. Special Club Fairs will be held, at which prizes will be given on lambs and sheep. It is expected that returns in wool and lambs will enable the boys and girls to meet their note when it falls due.—E. P. Bradt, Secretary for Agriculture.

FERTILIZERS FOR THE SEASON OF 1919-20

N. B. Agricultural Societies Will Supply New Brunswick and the Maritime Farmer Will Look After Nova Scotia

As predicted by the Maritime Farmer in its last issue, fertilizer prices will be lower in 1919-20 than they were a year ago. There is an appreciable difference in the cost of mixed and unmixed goods, except in acid phosphate which will be as high or higher than last season. There has been a strike in Florida among the rock phosphate workers, and production has been greatly curtailed. Then there has been a big demand for overseas shipment. Ammonias, nitrate of soda and sulphate of ammonia are much cheaper than a year ago, but the price has been going up and will be higher in the spring, if present indications mean anything. Potash will be available at half the price of last season or even less. The outlook, at one time, was for sufficient European potash to fill all requirements in America, but this promise is now discounted.

The New Brunswick Agricultural Societies United will be on hand this year with supplies of nitrate, acid phosphate and potash in mixed cars. It is also proposed to handle mixed goods in the same cars for those societies who want them. The average farmer can save a large sum of money by buying co-operatively. By mixing his own goods he can save many dollars as compared with the charges for mixed goods. But if he wants mixed goods, he can also cut his costs by a large margin, if he buys in car lots.

In Nova Scotia, the Maritime Farmer, will look after the interests of farmers who wish to buy in car lots. Get your neighbors together and arrange to buy straight unmixed goods or mixed. The prices will provide for cash payments and it will be necessary to have your local bank, that your draft be protected on presentation. If you are interested, write either organization, AT ONCE. Address all communications to either organization, N. B. Agricultural Societies United, Sussex, or The Maritime Farmer, Sussex, N. B.

HORTICULTURE.

N. S. ORCHARD FIELD DAY

On August 20th, upwards of three hundred enthusiastic fruit-growers of the Annapolis and Cornwallis Valleys enjoyed an Orchard Field Day, under the direction of Mr. Geo. E. Sanders and Prof. W. H. Britain, who have done so much to show the fruit growers of Eastern Canada how to combat their orchard enemies with a minimum of labor and expense, and with a high degree of efficiency. The procession consisted of sixty-one automobiles, as they went from orchard to orchard, where particularly interesting experiments could be noted. The party inspected a total of 150 acres of orchard—areas that were dusted according to the suggestions offered by Messrs. Sanders and Britain, in their 1919 spray calendar.

Among others the party included such noted fruit growers as S. B. Chute, W. W. Pinneo, John Buchanan, S. C. Parker, J. Elliott Smith, Fred and Ernest Johnson, Joseph Kinsman, Mrs. Sangster, Ray Clark, Geo. McLean, E. I. Loomer, Stanley Banks and Kenneth Pinneo.

Another interested member of the party was Prof. H. H. Whetzell, head of the Department of Plant Pathology for New York State, who having heard of the success that the fruit-growers of Nova Scotia were attaining in the growing of clean apples by the use of the new dust spray, discovered by Mr. Geo. Sanders, came to see the results of the experiments at first hand, so that he might be able to pass the ideas on to the fruit-growers of his State.

Starting from J. Elliott Smith's orchard near Wolfville, the party next visited Ernest Johnson's orchard, where he had used the new Bordeau dust in a large commercial way, and succeeded in getting one of the cleanest crops of Gravensteins in the Valley. In the Dexter Collins' orchard, the fruit growers compared the results procured by the use of various spray calendars, after which the next point of interest was in the Experimental Station orchards, Kentville, where the new copper-lime-arsenate dust was tested on potatoes as well as the new stock solution method for using white arsenie in liquid Bordeaux. In both cases the insect and blight control was perfect with no foliage injury in evidence. From the Experimental Station the party proceeded to J. Howe Cox's orchard at Cambridge, where a number of spray calendars were tested, and thence to S. B. Chute's orchard at Berwick, where fifteen acres had been dusted. Here the dust was checked against the 1919 spray calendar. Here again the new copper-lime-arsenate dust gave as good, if not better, results in growing a clean crop of Gravensteins than did the liquid spray, while the unsprayed check trees carried a 95 per cent. scab infested crop.

At the Senator W. B. Ross orchard in Middleton, various spray calendars were compared and it was there again demonstrated that the fourth spray of lime-sulphur removes from the trees a large portion of the crop of apples in Nova Scotia. This injury is estimated to have caused a loss of at least 200,000 barrels of apples a year in Nova Scotia since 1912.

This year the Nova Scotia fruit growers have gone back to Bordeau and soluble sulphur and consequently have the first big crop since 1911, when the crop was 1,700,000. This year's crop is estimated at at least one and one half millions of barrels. The crops intervening between 1911 and 1919 ran much less than one million barrels.

Again at the Elvin Schaffner orchards, Lawrencetown, liquid spray calendars were compared, and the injury wrought by lime-sulphur demonstrated.

The Everett orchards, Bridgetown, were next visited and there lime sulphur versus no spraying and Bordeau was compared.

From the remarks made by the apple growers on the trip it would appear that they are all going to follow the practice of dusting as rapidly as they can change over. It looks now as if second hand spray rigs could be bought very cheaply in the Valley.

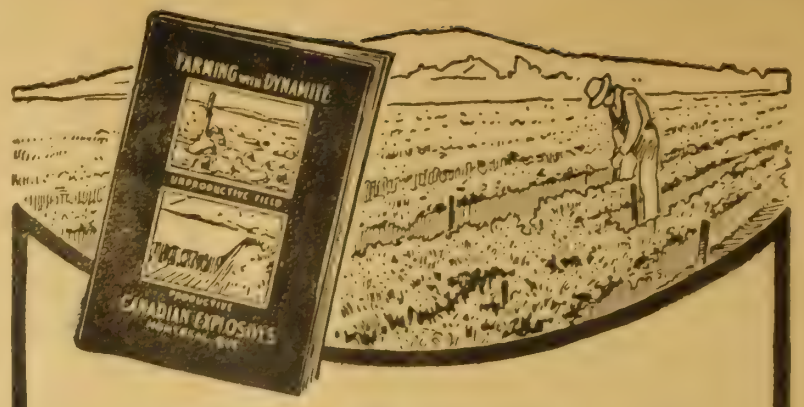
The supremacy of the 1919 spray calendar over all its predecessors was amply demonstrated and was acclaimed as the first absolutely satisfactory calendar.

Dusting as carried on gives the best results when aplied on early damp mornings on still, damp days and may be applied about ten times as fast as liquid spray, so that in treating an orchard with dust one may use time which cannot be otherwise used for any other field or farm purpose to advantage.

With the low cost of the copper-lime arsenate dust, invented by Mr. Geo. Sanders, dusting will be a great deal cheaper than liquid spraying and it has this year shown itself to be equally effective. It will also enable fruit growers to carry on farm work and care for their orchards, a practice which is almost impossible where liquid spraying is conducted.

Prof. Whetzell was delighted with this, his first visit to Nova Scotia. He found the tree heavily laden with an uniformly good crop. He considered the fruit in the dusted orchards of higher grade and better finish and was ready to acclaim that Bordeaux dusting is certainly as good as spraying. He considers however, that Bordeau dusting rusts the apples a little more than does sulphur dusting. Prof. Whetzel was delighted with the enthusiasm evidenced by the Valley fruit growers in the dusting proposition and forecasted a heavy demand for dusting machinery in the near future. He returns home to report what he saw to the fruit growers of his state. He was also very much interested in his visit to the United Fruit Company's headquarters, where Manager McMahon gave him an insight into the possibilities of co-operation and the success it is attaining among the fruit growers of Nova Scotia.

The tools and facilities required for keeping harness in repair are comparatively simple and inexpensive. A considerable portion of the repair work on harness can be performed by the aid of tools required for other purposes, but these are a few special devices that are desirable.



This Free Book Will Help You Make More Money

It shows you how farming—whether on new land or old—can be made doubly profitable, how acreage can be increased, labor saved and crops made larger.

"Farming With Dynamite" is a book that you should have. Get your copy today and learn how C. X. L. Stumping Powder will help clear that stump lot, remove the boulders, dig your ditches, either for drainage or irrigation, and blow holes to plant fruit trees that grow faster and bear earlier and heavier than spade-planted trees.

From the standpoint of crop cost you cannot afford to be without C.X.L. Stumping Powder. This free book tells you all about its use and how it helps increase your profits.

HOEING PAYS IN CORN AND ROOTS

The introduction of improved methods of agriculture and the use of labor-saving implements in Canada can be dated back to the time this country was captured from the Indians, and while development has been steady, their use was greatly accentuated by the war. Help was scarce and hand labor reduced to the minimum, during the past four years, consequently the only alternative was to use machinery wherever possible. The success of that change can be judged best by the crops obtained, facturers. In many cases the substitution of implements for hand labor had a beneficial effect, largely because the work was done more frequently, but there was on every farm, an apparent lack of hand hoeing.

It may be all right to plant hoed crops in elevated ridges, check rows and cultivate both ways, but there is nothing that can replace the hand hoe. No horse drawn implement can go as close to the plants, and no implement has as yet been devised that will remove weeds that grow between the plants and keep the ground stirred except between the rows. But such work is essential if a maximum crop is to be expected, and it cannot be done without more or less hand hoeing.

The work of hoeing may seem very simple, but there is a great "knack" in doing it, in fact there are very few men who are real experts at the job. However, hoeing is not hard to learn; it requires common sense and patience and cannot be done at "break neck" speed as many people suppose. The best hoers in the world are the men of the British Isles, and it is most interesting to watch them doing the work. Going at it in a systematic way they work very easily and cover a great area in a day.

They stand sideways to the work, one row across, and by so doing every stroke counts. They use hoes with blades set at right angles to the handle instead of the acute angle of those sold in Canada. Furthermore, they have both ends of the hoe sharp, thereby giving them three sharp edges instead of one as is the case with the Canadian hoes. With this hoe it is much quicker and easier to do the work, as it can be used both ways, pushing away from the operator and drawing towards him. It is not uncommon for men using such a hoe and working in land free from stones to weed or thin from half to three-quarters of an acre per day, and some can do even more. The position of the operator and the shape of his hoe are the deciding factors between easy and difficult, fast and slow work, and every man who intends to do any amount of hoeing should readjust his hoe to fit the work. It is a simple matter and can be done by any handy man or blacksmith by first squaring the ends of the hoe with a cold chisel and filing them as sharp as possible as well as the face. Then place the neck of the hoe in the fire and heat it until the blade can be bent back till it is at right angles with the handle. It will only take a few minutes to do this, but it will save many hours of work as well as the tiresome task of back-bending to remove weeds or surplus plants.

A Correct Lubricant for every Farm Machine

NO ONE LUBRICANT WILL DO FOR ALL

Farm machines differ in structure and in service and so require different types of oils and greases. Farm tractors require different lubricants from trucks and automobiles—different parts of the same engine or motor having different duties to perform cannot be properly lubricated with the same oils and greases. Good lubrication will save you hundreds of dollars every year over poor lubrication. Imperial Farm Lubricants provide the right kind of oil or grease for each farm machine. From the Imperial Line you can select a lubricant that gives the greatest operating efficiency for each.

Look over the Imperial brands recommended here. These names are all recognized by Canadian farmers as standards of high quality. Imperial Farm Lubricants are scientifically formulated and carefully made. There are no superiors and few equals. Properly used they will increase the years of service from your automobile or tractor and all the other machines on your farm. Imperial Lubricants come in one-half, one and four-gallon sealed cans; in steel half barrels and barrels. The kind you want in the size you need can be delivered to you promptly anywhere at any time.

For Steam Cylinder Lubrication, whether Tractor or Stationary Type.
CAPITOL CYLINDER OIL

COMPARISON OF THE DIFFERENT KINDS OF WINTER STORES FOR BEES

(Expermental Farms Nate.)

In the experments with bees at the Experimental Farms it was early recognized that the nature of the winter stores is an important factor in successful wintering, and the experiments have confirmed this. Experiments at the Central Experimental Farm indicate that clover honey (alsike and white clover) makes reliable stores for wintering, but poor results have followed the use of stores that granulate hard during the winter. A colony wintered on dandelion honey came out in spring very weak; the honey had granulated hard and the bees had uncapped it but could use very little of it. In some years a mixed honey that comes largely from clover, sweet clover, and other plants granulates hard with the same result and causes heavy loss. Buckwheat honey has been found wholesome, but some of the other honeys gathered in the fall have been found unwholesome, especially in marshy places in Nova Scotia, and have caused dysentery and death. In one season in Northern Ontario, the fall honey was not capped over and failed to ripen and soured, causing dysentery and heavy loss. Honey containing juices collected by the bees from over-ripe fruit killed a colony before spring, so also did cane syrup used as an exclusive food for wintering. Syrup made from refined sugar, two parts of sugar to one of water, fed to the bees in the early fall, has given fairly good results as an excluise winter food, and has been found to be the best practical corrective for stores that are slightly unwholesome. Year after year at the Central Farm, colonies on natural stores that have been fed liberally with this syrup come out stronger in spring than those that have wintered on the natural stores alone. Syrup made from raw cane sugar has given less satisfactory results than that made from refined sugar.—F. W. L. Sladen, Apiarist, Dominion Experimental Farms.

UNFIT SEED PROHIBITED

Regulations are now in force which prohibit the importation into Canada, in lots of ten pounds or more, of unfit seed of clovers, grasses, vetches, rape, other forage plants, field root and garden vegetables.

Unfit seed is described in Pamphlet S-12 of the Seed Branch of the Department of Agriculture at Ottawa, and obtainable from the Publications Branch, as that which does not comply with the Seed Control Act requirements respecting the sale of seed in Canada, or if it has been refused admittance into any other country on account of low vitality.

The regulations governing this matter are fully described in this pamphlet which shows that unfit seed that has arrived in Canada shall be deported under Customs supervision. Penalties are attached to infractions of the law in this regard.

DAIRYING

COOLING CREAM PROPERLY BEFORE IT LEAVES THE FARM

Every dairy farmer who makes a business of selling cream during the summer months has, from time to time listened to all kinds of advice and instructions, on the why and how of cream cooling. While no doubt some of this advice has been acted upon, still a great deal of it has received very little attention from dairymen generally. There are reasons of course, why the cream producers do not seem overly anxious to go to any more trouble with the cream while it is in their hands than the law calls for. One good reason is, that the parties inclined to give advice as to the necessity of properly cooled cream, have failed to present reliable concrete facts and figures to bear out their statements, that such cream makes higher-scoring butter which brings larger returns from the market than that made from poorly cooled cream. This together with the unwillingness displayed by the manufacturer to pay for cream on a quality basis, largely accounts for the half-hearted interest which the dairy farmer has shown in the subject.

Facts and Figures

To remove the air of uncertainty about this matter, and to show reasons why cream should be properly cooled, an experiment was conducted recently at the Government Agricultural Experiment Station, Purdue, Indiana. Two cream routes with twenty patrons each were selected. Each route was divided into two parts; half of the patrons received cream cooling tanks, and the other half took care of their cream without the use of special tanks. The patrons with the tanks were instructed as to how they should be used, and a member of the staff visited these farms weekly to see that instructions were being carried out.

The cream was hauled to the creamery twice a week, that received from the patrons using the tanks being carefully kept separate from the cream sent in by the no-tank patrons. Both sorts of cream were scored by tasting and smelling, tested fo racid and bacteria, as well as for fermentation and sediment. Butter was made from the two kinds of cream in exactly the same way to the very last detail.

The records of this experiment bring out the following facts:—

Quality of the Cream

In every case the cooling tank cream, tested on reaching the creamery contained less acid than the no-tank cream; the average being .35 per cent, and .52 per cent. acidity respectively. This difference represents a reduction of acid, due to the use of of the acid contained in the no-tank cream. Furthermore the records show, that in every case the cooling-tank cream scored higher than the no-tank cream, the average scores being respectively 91.25 points and 88.75 points. In the case of tank cream the flavor was uniformly clean, while the uncooled cream had in most cases an unpalatable flavor; sometimes it was cheesy; at other times yeasty.

It was also shown that the use of cooling tanks reduced the bacterial count of the cream by 35 per cent., and cut down the number of yeasts and molds by 75 per cent. When it is considered that yeasts and molds are the causes of most of the unpleasant flavors, and the rapid deterioration of butter, the importance of this item is quite apparent.

Quality of the Butter

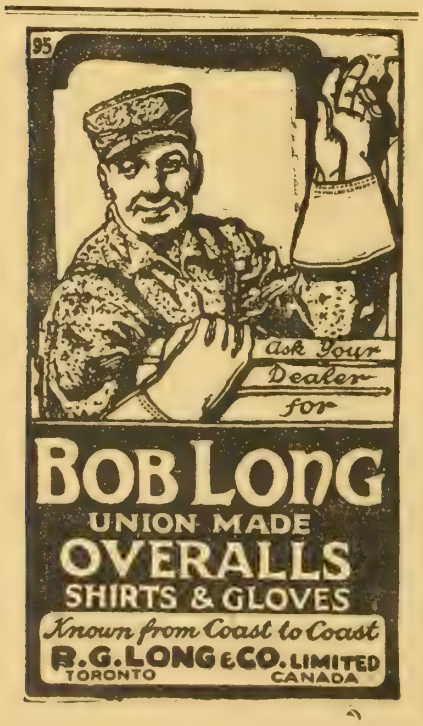
The butter made from the cooling-tank, and the no-tank cream, was carefully scored by two sets of competent judges. The important and convincing feature of this part of the experiment was, that in all cases, except one, the tank cream butter scored uniformly higher than the no-tank product. The average of all scores was 90.69 points for tank cream butter, and 88.36 points for no-tank cream butter—a clear difference of 2.33 points in favor of the tank cream butter. A difference of two points in the quality of butter, may not seem like a big item, but it means more than would appear at first sight. An 88 point butter is no longer considered good butter. It is disagreeable to the palate of the rank and file of the consumer, and so retards demand and invites competition from butter substitutes, and imported butter. Butter scoring 90 points or better such as even the dairy farmer can produce by properly cooling his cream, on the othe rhand, meets with the approval of the bulk of the consumers, and is considered good butter. In short this experiment has shown that proper cooling of the cream can readily make all the difference between butter which can be classed as good, and an inferior product.

In the matter of market returns, the average price received for tank butter proved to be a clear cent better than the average price for the no-tank product. This difference would undoubtedly have turned out to be greater, but for the fact that the month chosen for the test—August—proved to be exceptionally cool.

Cream Cooling Tanks

Providing a cream cooling tank on the farm need not be a very elaborate operation. A perfectly satisfactory cooling tank, big enough to accommodate two cans may be made out of an ordinary pickle or vinegar barrel which has first been thoroughly washed. A simple bit of a frame made out of three small boards at the top of the barrel, and a similar frame at the bottom of the barrel will answer to hold the cans upright. It is a very simple and convenient arrangement, to place this barrel between the pump and the tank or vat used for watering the stock, whether inside or outside of the stable; in this case all the water pumped for the stock is first used for cooling the cream.

To make a long story short, almost any farmer can, with very little expense, contrive some sort of an arrangement that will do the job satisfactorily. One other point should be noted, and that is, the tank provided should be big enough to take care of the cream from at least two milkings. If this is not the case, it will be found necessary to mix warm cream and cold cream—a practice which cannot be condemned too strongly, as cream so mixed will ferment very rapidly, with the inevitable result of giving an inferior product.



Chilled to the Marrow!

PURCHASE OF CANADIAN CHEESE BY BRITISH BUTTER AND CHEESE IMPORT COMMITTEE

Following the recent collapse of the cheese market, a representative of the British Ministry of Food (Mr. F. Warren) and the Chairman of the Butter and Cheese Import Committee (Sir Thomas Clement), associated with the Ministry of Food, London, England, were in Canada last week for the purpose of arranging for the purchase of 20,000 tons of Canadian cheese. They met the producers at Brockville on Thursday and offered 25 cents per pound delivered at Montreal. Sir Thomas Clement announced that a local committee to represent the British Butter and Cheese Import Committee would be formed in Montreal to arrange for the export of the cheese. The Canadian merchants who handle the cheese are to be paid a commission of 1½ per cent plus ¼ cent per pound to cover handling charges.

Taking advantage of his presence in Ottawa today, Mr. Warren was asked for a statement as to the reasons for the purchase and why they are unable to pay more than 25 cents per pound. His answer was as follows

"The maximum retail price of "cheese in Great Britain, including "the home production, has been fix-

"ed by the Ministry of Food at 1/6 "(36c) per pound and there are sufficient reasons why the maximum "cannot be raised.

"The cost of handling the cheese "from the time it is delivered by the "Canadian producer at Montreal until it reaches the consumer in Great "Britain at the present time amounts "to 10.95 cents per pound made up "of the following items:

	Cents per lb.
"British retailers' profit (which includes loss in weight in cutting up).....	5.
"Commission paid to British Wholesalers and British Importers (average).....	1.5
"Inland transport in Great Britain	.5
"Storage and handling in Great Britain.....	.5
"Interest in carrying stock..	.5
"Loss in weight.....	.33
"Ocean freight and landing charges	1.75
"Discount	.25
"Commission paid Montreal Exporters	.37
"Montreal handling charges.	.25
Total $10.95	

"In addition to these charges the "British Committee will have to bear "the loss on account of the low rate "of exchange, which at the present "time is equivalent to about 2 cents "per pound.

"The British Committee will lose "on the Canadian cheese purchased "at 25 cents and this loss will have "to be met from the profits on pur"chases in other countries, or be"come a charge on the British Trea"sury.

The foregoing figures are confirmed by Dr. Jas. W. Robertson who has just returned from England.

There is no "fixing" of price and the Dairy Produce Commission will not be revived. Producers are free to dispose of their cheese through any other channels and at a higher price if that should be possible.

J. A. RUDDICK,
Dairy & Cold Storage Commissioner.
Ottawa, Ont.

DOES SELLING WHOLE MILK PAY?

Why is the farmer who sells whole milk to a condensory, or supplies it to the city trade, entitled to more money for his product than the dairyman who disposes of his cream only or patronizes a cheese factory? To answer this question satisfactorily several factors, such as convenience, roads, etc., all of which have a direct bearing on the matter, must be considered; but in a general way it may be said that selling whole milk off the farm entails a great loss in fertility, to replace which costs considerable at prevailing costs.

It should not be the aim nor desire on the part of any farmer to go on year after year mining his farm of fertility, leaving behind him rundown, worn-out land for those who follow in his footsteps. On the contrary, his ambition all through life should be to make an honest living and acquire from time to time what money may be required to clothe, feed and give his family what education may be necessary; moreover, to increase through his efforts greater value and fertility of his soil, so as to be able to hand down a more valuable heritage when he is through with it. To do this is not by any means an impossibility, in fact it is being done every year on many farms right here in Central Canada. However, this cannot be accomplished by the farmer who continues in selling whole milk year after year without spending money to buy fertility, either in millfeeds for his cows or commercial fertilizers for the land. The amount of fertility lost in selling whole milk in preference to cheese or cream means a difference of several hundred dollars annually in the case of a twenty or twenty-five cow dairy, for, according to investigations carried on by foremost chemists, the amount of fertility sold in cream is very small, and only about 50 per cent. in the case of cheese as compared with whole milk.

Another argument against selling whole milk off the farm is that the practice requires too much specialized work on the part of the farmer, for, as pointed out in the report of the Dundas County Survey, no farmer makes the maximum labor income without the use of side lines such as hogs, poultry, etc., to carry on which is rather difficult for the man who is shipping whole milk. All this tends to decrease the net profits and demand a certain percentage of the extra money obtained also is the question of raising calves, for whole milk. Coupled with that also is the question of raising calves, for there is a great loss sustained by the whole milk shipper in not being able to supply his calves with dairy by-products, which results in either the calves not being fed to the best advantage, and consequently not develop into choice dairy animals, or having to be fed whole milk. In the case of the latter, unless they are very they are actually worth. The outvaluable, their feed bill is more than they are actually worth. The outcome of the whole thing is that the farmer whose herd consists of grade cows, becomes careless about raising calves, preferring to buy milkers as needed.

That brings up another great difficulty, which costs the whole milk shipper considerable money during a period of say five or ten years. Good cows are very expensive and short-lived, but coupled with that is the great risk of buying animals affected with tuberculosis and contagious abortion. True, these dreaded diseases are not confined to herds producing milk for city trade only, but it is easy to understand that in the case of a home grown herd, where the animals are healthy, their calves raised stand a good chance of being the same, while another herd of equally healthy animals may be ruined by bringing in a few cows that carry disease. Tuberculosis can be detected if the cows are tested, but that is not always done with grades, but on the other hand contagious abortion cannot be detected before it is too late. It is a most serious situation and one that requires a great deal of careful thought before beginning, for, above all things, farmers cannot afford to court either of these diseases.

Any business which thrives must be continually improving, and it is very difficult to improve the milking qualities of the dairy herd if the cows are brought in as needed. Few farmers will sell their best cows, and once a certain standard of production is reached the yield becomes almost stationary. With a herd where young animals are being raised annually, the average yield can be brought to a higher level. By using a good, pure-bred sire the profit per cow can be doubled, as was proven by the Oxford and Dundas Counties survey. These things cost money, which must be met in the difference in price received for whole milk as compared with either cream or cheese.

The foregoing are a few of the obstacles confronting the farmer who forsakes the cheese factory or creamery, and in making that sacrifice he should receive increased remuneration. The loss of fertility, the difficulty of utilizing side lines, of growing hogs, calves, etc., the danger of bringing in diseases, the difficulty of increasing the production of the herd, must all come out of the price of the whole milk. And remember it is not all profit, as many farmers think, when they hear that their neighbor received a dollar per hundred more for his whole milk than they got at the cheese factory.

Encouraging the Sheep Industry

INDUCEMENT TO USE A PURE BRED RAM AT THE HEAD OF YOUR FLOCK OF SHEEP

The New Brunswick Department of Agriculture are Co-operating with the Dominion Live Stock Branch in Encouraging the Use of Pure Bred Rams

Persons Eligible

Any sheep raiser who purchases a pure bred registered ram and who has not before at any time used a pure bred ram in his own flock shall be entitled to a premium of ten dollars the first year; Five of which will be paid by the New Brunswick Department of Agriculture and five by the Dominion Live stock Branch, and an additional premium of Five Dollars the second year, payable by the Live Stock Branch. Applications for premiums to be sent in to Live Stock Division, Department of Agriculture, Fredericton, not later than December 1st.

Co-operative Purchasing of Pure-Bred Stock

The Dominion Live Stock Branch will pay the travelling expenses to any point east of Fort William, Ontario, of any accredited man appointed by a Society, group of Societies or group of farmers who have orders to purchase at least twenty-five pure bred rams for farmers never having used a pure bred before. This same person has the privilege of making purchases of other live stock or rams for any farmer while on the trip, so long as the minimum of twenty-five rams are purchased as outlined above.

Grading of Pure Bred Rams in New Brunswick

The services of Professor Sackville of Ontario Agricultural College, have been secured to visit each pure bred breeder in the province and classify the rams offered for sale into three grades, superior—average and common. By purchasing your rams in the province, farmers can write any breeder of pure breed sheep and be sure of getting the class of ram he applies for. New Brunswick is the first province to adopt this classification system. Breeders and Purchasers stand to gain by it. The number of rams for sale together with the price and grade will be listed with the local Live Stock Division.

Boys' and Girls' Sheep Clubs

In order to create a deeper interest among our farm boys and girls in the business of sheep raising, arrangements have been completed to organize Sheep Clubs in the province. Members must be between ages of ten to eighteen years. Ten members will constitute a Club. Two grade Shearling ewes will be the number alloted to each. Members can get credit from any bank for purchase price of sheep for one year at 6% interest. The Department will arrange a fair at which prizes will be given. The Department will loan a pure-bred ram to any Club with twenty ewes.

For information on any of the above policies, write

THE RESULTS OF CROSSBREEDING

The meaning of "crossbreeding" is not always definitely understood. As generally understood it means the mating of animals of entirely different breeds. The use of purebred sires upon scrubs or grades of the same breeding is usually spoken of as "grading up." There are always definite reasons assigned for this practise, but after all the underlying reason for crossbreeding most often is a curiosity to see what the result will be. Many times a breeder has a theory that the product obtained will combine the good qualities of each breed. Crosses of Jerseys are made with Holsteins in the hope that the resultant offspring will produce milk as rich in butter fat as that of the Jersey and in as large quantities as that of the Holstein. Crosses of hogs are expected to possess the prolificacy of one breed and the size of the other, and crosses of fowls are expected to possess the laying qualities of one breed and the size of the other. The result is just as probable that the heifers produced will give milk possessing neither the richness of the Jersey milk nor the flow of the Holstein, the hog produced be low in prolificacy and small in size, and similar results may follow with fowls.

The Usual Low Standard Practice

That crossbreeding is a continual experiment may be shown by observing the general practice of communities. The usual practice of those who crossbreed is, as soon as the theoretical result is not obtained, to try a cross with some other breed. The man who practices improvement by grading up ascribes the fault to the sire, when unsatisfactory results are obtained, and he straightway purchases a new sire of the same breed and thus his breed grows better from year to year. When poor results are obtained by the man who practices crossbreeding, a change of breeds is made in order to make the results conform with his theory. The live stock of communities where crossbreeding is practiced is always of low standard.

Grading up effects improvement. continued crossbreeding causes live stock to degenerate. Crossbreeding for the purpose of securing an intermediate between two breeds is unwarranted at the present time. Today there are many breeds of live stock representing practically all possible types. Some of these breeds have required over 200 years of selection to bring them to their present standard of perfection. In fact, those breeds are most perfect that have been selected for the greatest number of generations. The same principles that have been used in effecting breed improvement should be employed in improving the live stock upon each farm. The man who employs the grading up method of improving his live stock can have in three generations of breeding as good live stock of any particular breed for market purposes as are purebreds of the same breed. The first generation would be one-half purebred, the second three-fourths and the third seven-eights. A seven-eighths pure bred, whose parents and grandparents were selected for their desirable qualities, is as good for market purposes as pure-bred animals of the same breed. Such animals can not be recorded as pure breds, however.

Increased Vigor Without Crossing

It is true that increased vigor is very often obtained by cross-breeding but the fact should not be overlooked that the same vigor is obtained in pure breeds of live stock, That increased vigor is secured by crossbreeding has been proven by numerous experiments with grains by scientists, yet no greater vigor has been obtained than has been effected by mating unrelated plants and animals within varieties and breeds. Experiments that have been made in crossbreeding have not proven that crossbred animals are more vigorous than matings that may be made within the breed.

A close study of the different breeds of live stock will show that there are quite unrelated types within breeds where the differences of characteristics in conformation, quality and temperament are as great oftentimes as are the differences between breeds. If one wants to obtain increased vigor, then why not mate animals of the same breed but of different types and relationship? A cross will as truly be made as where animals of entirely different breeds are mated. Strong vigorous offspring will be obtained without the disadvantages of having them of broken colors and broken breeding.

Until the last few years it was not known why, when cross-bred animals were mated, the resultant offspring possessed a great variety of digerent characteristics. We now know that offspring from unrelated parents of dixerent types tend to be uniform in characteristics and also that when such cross-bred oxspring are mated they will be represented in the offspring, if they are numerous enough, by all of the characteristics that made up each of the breeds represented in the original cross. The fact should be borne well in mind that continued cross-breeding is always disastrous to

STOP YOUR FIRE LOSS "METALLIC" BUILDINGS ARE SAFE

WHY build with inflammable wood when you can get fireproof, weather-proof and lightning proof "Metallic" building materials. They are far cheaper in the end. "Empire" Corrugated Iron Siding is easily and quickly laid and makes a strong, rigid wall. Its light weight makes heavy construction unnecessary.

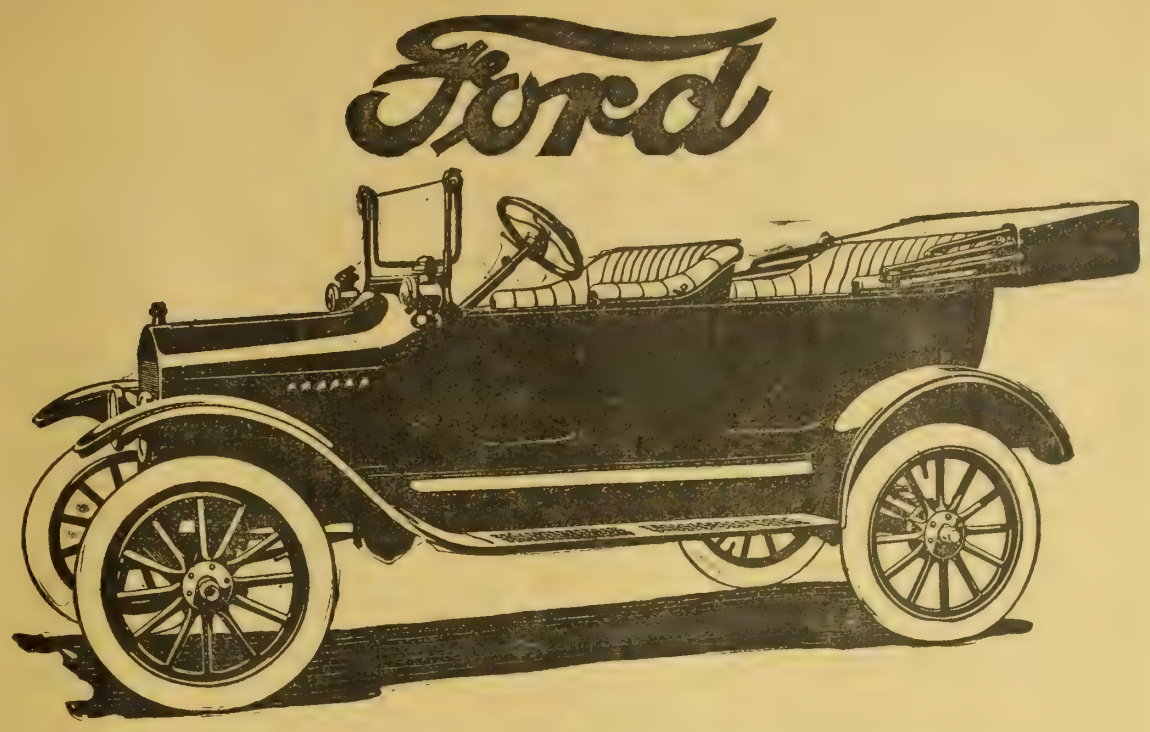
the live stock of any community. Uniformity of breeds is broken up and instead of progress being made the live stock of the community will represent the types of animals that existed two centuries ago. N. E. D.

GRADING UP THE FARM FLOCK
(Experimenta Farms Note)

In 1910 and 1911 a flock of Western range ewes was established on the Brandon Experimental Farm to be used as foundation stock in a grading up experiment. They were the usual type of range ewe, small and mean looking, showing a great mixture of breeding but with Merino blood showing up rather strongly throughout. These ewes were bred to a good pure-bred Oxford Down ram. When their lambs came to breeding age, another ram of the same breed was used and this line of breeding kept up consistently. The flock was increased about 50% in numbers at first, then bred at a uniform number each year. Each fall the least desirable of the ewes were culled out and the remainder kept for breeding. In the fall of 1916 the last of the original ewes were disposed of, and in the fall of 1917 all first cross eyes that showed in their appearance any sign of their mongrel origin were disposed of. Consequently the breeding flock in 1918 consisted of a lot of Oxford Down grades of uniform size and shape, all with dark brown faces and wool of uniform type. This complete change in the appearance of the flock was accompished in this short time simply by using each year a pure-bred sire. In this time the average size of the sheep was increased nearly 50% and the average wool clip about 30%. The first cross of Oxford on the range blood produced a sheep of decidedly Oxford character with an increase in size, but they were not uniform in appearance and many showed signs of the dam's breeding or lack of breeding. The second cross was a great improvement over the first, and the third cros resulted in a sheep that was practically indistinguishable from a pure-bred.

While the Oxford Down breed was used in this experiment, it is not the purpose of this article to recommend that breed above others. The range ewes were conspicuously lacking in size, and the Oxford was chosen particularly to increase the size. Other breeds that might have been used for that purpose are the Hampshire or the Suffolk of the Down breeds, or the Leicester, Cotswod or Lincoln of the long wools. Or, if breeding up is to attain more compact form, with earlier maturing, the Southdown or Shropshire might be used.

The results obtained in this experiment have been duplicated by many practical sheep raisers throughout the West. There is no reason why many others should not attain similar successes, changing their present nondescript mongrel flocks to fine, uniform, handsome flocks closely resembling pure-breds of the breed they choose to use sires from . The process is very simple, choose a good breed, buy good individual sires of that breed, stick to the one breed and reject the culls. This, with good general care, and feeding, will very quickly accomplish the desired result.



"A Joan of Arc Machine"

SHE withstood everything in the field and above all was, and still is, the last and only car to survive until the cessation of hostilities"—Extract from letter received by Ford Motor Company from a British Soldier, in Africa.

Over shell-torn roads, through water soaked fields, second only to the tanks in its power to climb debris and crater holes, the Ford car made a world famous record in the fighting area of the great war. In press despatches, in field reports, in letters, in rhyme and song the praises of the Ford were sounded.

In France	-	700 cars out of 1,000 were Fords
In Italy	-	850 cars out of 1,000 were Fords
In Egypt	-	996 cars out of 1,000 were Fords
In Mesopotamia		999 cars out of 1,000 were Fords

The Ford power plant that established this world-wide record in every theatre of the war remains the same. It will be in the Ford you buy.

Ford Runabout, $660. Touring, $690. On open models the Electric Starting and Lighting Equipment is $100 extra. Coupe, $975. Sedan, $1,175 (closed model prices include Electric Starting and Lighting Equipment). Demountable rims, tire-carrier and non-skid tires on rear as optional equipment on closed cars only at $25 extra. These prices are f. o. b. Ford, Ont., and do not include War Tax.

Buy only Genuine Ford Parts. 700 Canadian Dealers and over 2,000 Service Garages supply them. 119

COST OF SHIPPING LIVE STOCK TO FOREIGN COUNTRIES

Data on the cost of shipping cattle to foreign countries is furnished by the Market Department of the Bureau of Animal Industry at Washington. The cost of a shipment to Antwerp, Belgium, amounted to $125 per head, of which $100 went for transportation, $8.50 for insurance, $13.50 for feed and $3.00 for transportation and meals of attendants. The animals were grades intended for slaughter. Another shipment sent in June showed a total expense of $129.75 per head. South American shipments cost considerably more. A June shipment of Shorthorns to Uruguay figured $180 per head for the cow, for transportation alone, $105 for insurance, $75 for fittings, $20.25 for feed and $25 for attendants. The same transportation charge was made for a shipment of Shorthorns to Argentina, cows and heifers being figured at $180 per head while calves were taken at $90 each. From these figures it will be seen that grade Holsteins being purchased for foreign shipment will have cost considerable money before they reach their final destination on the farms of France.

GROUND GLASS NOT HARMFUL

Experiments recently carried out by the Army Medical Corps have entirely disproven the popular belief that ground glass is harmful to the digestive tract.

Glass was ground and sifted to secure varying degrees of fineness and considerable quantities of the material were incorporated in fresh meat the same being fed to hungry dogs. This was repeated in some instances on a number of days after which the dogs were killed and the digestive tract examined both with the naked eye and by the aid of the microscope and no injury whatever was perceptible. Before being killed the dogs apparently suffered no inconvenience and appeared normal in every way.

These findings should eliminate for all time the idea of glass being the cause of death in animals maliciously poisoned.—W. H. Feldman, Colorado Agricultural College, Fort Collins, Colorado.

The boy with a pig of his own today is the livestock man of tomorrow—provided his father does not beat him out of the money the pig brings.

THE BEST LINIMENT
OR PAIN KILLER FOR THE HUMAN BODY
Gombault's
Caustic Balsam
IT HAS NO EQUAL

THE HORSE

DEFECTIVE EYESIGHT IN HORSES DUE TO DARK AND BADLY VENTILATED STABLES

Many of the diseases that afflict the eye of the horse are due to the conditions in which horses, as a general rule, are subjected to in their domestication. If there is a strong preidsposition to disease in the eye of the horse, it is generally assisted by the heated and poisoned air of many stables. The heated air has a great deal to do with the production of eye troubles, especially inflammation, but poisoned air has a great deal more; for everyone must observe on entering a close stable early in the morning strong fumes of ammonia, which are painful to the eyes and make them run with water. It can be easily recognized what the constant action of this state of air has upon the horse's eyesight. The manure and litter of the barn often become heated and in odd corners of the stalls they get putrid through neglect in cleaning them out thoroughly every day, thus giving off fumes that encourage the rapid development of eye diseases. Very soon after the urine of the horse has been voided and where there is not immediate drainage away, it also gives off a pungent gas that is detrimental to a horse's general eyesight. If we are scarcely able to bear it when we stand in the stable for only a few minutes we need not wonder at the difficulty of abating inflammation in the eye of the stabled horse while it continues to be exposed to such painful conditions.

Eye Disease From Dark Stables

Horse owners may not be aware of another cause of inflammatory disease to the eye which horses are particularly exposed, viz., confinement in a dark stable.

Many barns in which horses are confined have no adequate provision to ensure sunlight into every corner, and horses are subjected to almost total darkness all the time when once the door is shut on them. Consider what are the horse's sensations when he suddenly emerges from a dark room into the full glare of the light he is dazzled and bewildered, and some time passes before his vision is distinct.

Let this be repeated several times a day, in bright sunshine of the summer or the glare of the winter's sun on the snow, and what will be the consequence? The sight will be disordered and the eye irreparably injured. This is happening to many horses day after day and year after year, where total darkness prevails in the stable.

It is a well known fact that most of the diseases that arise among all domesticated animals is due mostly to the housing conditions they are subjected to. Tuberculosis, the dreaded scourge among humanity and cattle, is fostered and spread through crowded and badly lighted homes and barns, and to the same degree can be assigned the causation and spread of eye disesases and influenza among horses.

The propogation of eye diseases from sire to his progeny, has also not been sufficiently considered by breeders. Let a stallion that is blind, or whose sight is defective, possess every other point and quality that can be wished, yet he is worse than useless; for a very considerable proportion of his offspring will almost assuredly inherit his weak eyes, or become totally blind. This is a fact established beyond doubt.

White Spot on the Eye

For cloudiness or white spots on the lens, which generally follows inflammation, ignorant owners and horsemen often resort to barbarous customs to remove it with chalk, salt, sugar, and even pounded glass, have been introduced into the eye mechanically to rub off the film. Such harsh and cruel treatment only recalls the inflammation, and immediately inflicts excruciating pain. The film is not on the surface of the cornea, and therefore not capable of being rubbed off.

The pupil fo the horse's eye is seldom black, like that of the human being, and its greyish hue conceals the recent film which may be spreading over the lens. In many instances in which the sight has been evidently affected or almost lost a different opinion of the condition of the eyes has been given by very fair judges. A soothing eye wash for chronic cases of sore eyes is made up as follows: laudanum, two drachms; extract of belladonna, one drachm; water, one pnt. Do not use the common eye wash, sugar of leod and water, as it leaves a dull leaden deposit on the eye ball, which is a permanent blemish.

Shying

Shying in a horse is very often more a symptom of defective eyesight than it is the result of a vicious habit. This has been proved beyond contradiction. A horse will manifestly mistake the nature of the object before him; he will run against that which he should have seen; or he will be terrified by a tree or bird, which should not have caused alarm. Against the misconception of a shying horse there is no defence. Horses grow shy as they grow old, and no intelligent person will be slow in attributing it to the right cause, a decay in the organ of vision through loss of convexity in the eye. There is a striking difference in the convexity of the cornea in the colt and ahe old horse; both of whom shy from opposite causes; the one from cornea too prominent and the other from one too flat.

In the treatment of shying, it is of importance to distinguish between that which is the consequence of defective sight, and that which results from affectation or skittishness. In any case severity is out of the question. If the horse is forced, by lashing of the whip, up to the object, the dread of punishment will afterwards

When you go into town on Saturday get an AutoStrop Razor
YOU'LL find the AutoStrop Razor so quick, so easy to "heft" and the shave it gives so cool, slick and comfortable, that you'll find yourself shaving when you used to pass it up before.
For with an AutoStrop Razor there's nothing to fuss or bother about—that's the beauty of it. A few turns on the strop and you have a blade that would vie with the exclusive barber's in keenness. Then a few light, caressing strokes and the whisker is all gone, leaving your face smooth and refreshingly comfortable. To clean the razor, merely dip it in the basin and wipe it off. There's nothing to take apart, nothing to put together. From first to last—stropping, shaving and cleaning—the blade remains in the razor.
Sold everywhere with a money-back guarantee—Razor, strop and 12 blades, in an attractive case, complete, $5.

Auto Strop Safety Razor

be associated with that object, and on the next occasion, his shying will be more dangerous. On the other hand a horse if handled in a humane manner will come to have confidence in the man who drives or rides him. But it should be remembered, however, that although a horse that shies from defective eyesight—may be taught considerable reliance on the man who is guilding him, he can never have the cause of the habit removed. The human sight can be artificially strengthened, but the horse's must be left to itself. Selection in breeding, and well lighted and well ventilated barns are the preventative measures to insure horses against eye disease and defective eyesight.

HORSE CARE CALENDAR.—NAIL IT TO STALL OR POST

Do not fail to provide clean, warm quarters in which your mares can bring forth ther young. Naval ill comes from dirt.

It is dangerous to expose young stock, especially foals and colts, to spring rain storms. A day's exposure if not fatal, may stop a month's growth.

It is bad policy to turn the stock to pasture before the grass has well started—bad for the pasture and bad for the stock.

When the pasture season begins, turn the stock out at night, instead of in the morning. Then they will feed through the night, and not lie down untl the sun has warmed the air and the ground.

Get your horses into conditioon for spring work, the young horses especially. Many a colt has been ruined by being put to hard work without preparation. It is the same with green horses.

In warm weather thorough grooming is almost as important as feeding. Without it, dried sweat, dead skin, and dirt cog the pores, make the horse uncomfortable, and affect his health.

Look out for sore shoulders and backs, especially in plowing. Be sure that the collars fit. A collar too big is as bad as one too small. If the collar rides up, use a martingale, or a girth running from trace to trace, back of the forelegs.

When the horses are at work on a warm day, lift up the collars now and then to cool their shoulders, and wipe off the sweat and dirt with a bunch of grass.

Wipe off the harness marks on your horse when you stop work at noon and at night, and clean the inside of the harness, the collars especiallq. The salt sweat, drying on the skin and on the harness, is what makes the trouble.

If the skin is wrinkled under the collar or saddle, bathe it with diluted vinegar or witchhazel. If the skin is broken, bathe it with clean, warm water containing a little salt. Fix the collar, with padding or otherwise, so that it will not touch the sore spot the next day. A little carlessenss at the beginning may cause a lot of trouble to you and suffering to the horse.

Clean your horses at night, water them, give them a good bed, and water them again after they have eaten their hay so that they will not be thirsty all night. Let them rest an hour or more before they are grained. The observance of these simple rules will not cost you a cent, and will make a big difference in their condition.

REARING ORPHAN FOAL

I had a mare that died from sunstroke and left a young colt. It is one month old and it eats hay and a little oats. I give it milk with a little water in it. Am I treating it in the right way?—S.

Cow's mlk furnishes the most logical substitute for mare's milk, and the only available in most cases, but it is well to realize that as the composition is somewhat different, certain changes and modifications have to be made in order that the substituted diet shall not be too dissimilar from the natural mare's milk. The following table of percentages gives the average composition of the two kinds of milk:

	Milk from Cow Per cent.	Mare Per cent.
Water	87.17	90.78
Protein	3.55	1.99
Fat	3.69	1.21
Sugar	4.88	5.67
Ash	.71	.35

To make milk from the cow as near like that from the mare, the milk should be taken fresh from the cow and diluted with about one-fourth of pure water. A tablespoonful of lime water shoud be added to each pint of the diluted milk and the mixture should be given the orphan foal at about body temperature.

In feeding a young foal that loses its mother at birth, one-half of a teacupful of the milk should be given each half hour, the quantity being increased slightly and in the intervals lengthened gradually as the foal grows older. When the cot is about two months old, skimmed or separated milk may be substituted for the whole milk, and by this time one of the following rations should be fed alone with it:

1. One part of linseed meal boiled to a jelly and mixed withe two or three parts of bran.

2. Two parts of ground oats and one-half part of linseed meal, the latter boiled to a jelly.

3. Two parts of bran, two parts of oatmeal, and one part of oilmeal.

A double handful a day should be fed to start with and gradually increased. The foal should have company, and a calf is good for this purpose. A grassy paddock to run in must also not be forgotten.

CURRYING HORSES

Every healthy horse delights in rolling on the ground after a hard day's work, as soon as the harness is off. He is tired and sweaty, and his nerves ache for a touch of the ground, soothing to the skin and muscles.

A good roll is helpful and restful, but it does not do all it should do to rest a horse after his hard labor. It can easily be improved upon by using a good brush and currycomb. If he is sweaty and lathery, have a rubber similar to a window washing rubber, and rub him nearly dry. Then curry him and bursh him, and when he rolls, he will feel almost like a new horse.

We all know how a good bath rests us after a hard day's work. Currying a horse has practicall the same physical effects upon him as a bath upon a man. It soothes the skin, rests the nerves, cleans his coat and stimulates his circulation, so that his heart lungs and muscles can take full advantage of the night's rest.

HOOFS ARE BRITTLE

I have a horse, five years old, with very brittle hoofs, that will not carry shoes. What can I do for them?

This condition of your horse's hoofs is often found in diseased feet or where the peripole has been rasped off the hoof wall at shoeing. For diseased, brittle feet, a hoof ointment is very useful. Liquid tar, beeswax, honey and glycerine, of each an ounce lanoline and vaseline, three ounces each, is a useful preparation. The grawth of the hoof will be stimulated by repeated mild blistering. Liquid contharides is a very useful preparation for this purpose and should be rubbed into each coronet for about three minutes. The coronet is that part of the foot where the hoof and hair meet. In order to obtain good results, it is essnetia to anoint the part daily, after the blister has been applied with colza oil. The blister may be repeated after a month.

REMEMBER THE TIRED HORSE

When a horses' strength has been overtaxed, he must on arriving at the stable, receive special attention or wors etroubles may be in store. The first thing after he is unharnessed is to clothe him an dif possible, quickly have some gruel prepared. As soon as he has taken this, or while it is being prepared, if the ears are cold and drooping these must be gotten warm by friction. It is wonderful what an effect this will have in restoring a horse, a moderately tired horse wil soon become a different animal, showing evident appreciation of the process by holding his head down to receive the rubbing. No attempt at grooming should be made until the gruel has been taken and the ears are warm. In the course of an hour the grooming may generally be completed but not time should be lost in it, and the skin must on no account be allowed to chill. After it has ben been done the usual feed of oatts and hay can be given.

POULTRY.

WHAT GOOD SHOW BIRDS ARE

Having assumed that the farmers of Maine, who have been raising some good poultry this year, or even last year, the question arises, what are the birds that are suitable to show and stand a chance of winning prizes where there is sharp competition? In the smaller fairs it is likely that very little attention is paid to standard methods, but at the larger fairs the judges will likely to adhere pretty closey to the rules laid down in the Standard of Perfection for those varieties included in that book.

Show birds the not necessarily the best breeders or the best layers, but they are the birds which best conform to the type which they represent, as laid down in the standard. For instance, the bird must be of proper shape and color, must have a perfectly formed comb, is single, except in one or two of the breeds rare in Maine, there must be five distinct points and no more. The legs, beaks, wattles and ear lobes must be of the proper shape, size, and color, or the bird is likely to be disqualified or at least subejct to score cutting for so many slight defects that it will stand no chance of winning. One or two small feathers or sprigs on legs where there should be none, are sure to throw the birds out altogether, as also do one or two colored feathers on a white bird. This does not mean that such feathers can be plucked, for indications that such feathers have been removed will just as surely disqualify the bird. There are so many little things that either disquaify or at least count against birds that are really fine birds, that each breeder before exhibiting single birds or pens should make a careful study of the requirements for his particular breed or breeds, so that he may be able to pick the birds most likely to win, which he cannot do without accurate knowledge of the requirements of the standard.

Shape, weight, color and comb may be singled out as the four cardinal points in determining the qualities of a bird for show purposes. Shape is of great importance, and means proper form for the breed in all sections. A bird of Wyandotte type cannot hope to win in the Plymouth Rock class, no matter how beautifully it may be barred or colored. It is just as true that a bird which is considerably under or over weight cannot win where there is much competition, and, ordinarily speaking, birds scoring under 90 points out of the 100 must be discarded, even though the best birds in the class shown. Color is also of the utmost importance, and unless the birds are of solid color, the right arrangement of color must exist in all sections to assure any degree of certainty of obtaining even honorable mention, for breeding for colors is so carefully done nowadays that properly colored birds are not too rare to be found in competitions almost everywhere.

As to comb, that too, must conofrm to the rules as to size, shape, number of points, smoothness, spike, and general qualities and birds, especially male birds, with poor combs, however good otherwise, are often discarded altogether at the start, and if not really disqualified, are at once looked upon with disfavor by the competent judge. What every breeder needs to do is to study the standard and then breed as closely to its requirements, buying only birds that are close to it, and breed for improvement wherever he can see the need of, particularly making it a point to observe the superior points of the birds which win over his. But every farmer who has good birds will gain by showing them, whether he wins any premiums or not. Experience is the best teacher.—H.L. Goodwin in the Maine Farmer.

THE WATER GLASS METHOD

The watre glass method is the easiest and cheapest way to peserve eggs for home use. Water glass is a somewhat alkaline substance that can be bought at a feed or drug store. When diluted it will not injure the hands. A gallon will preserve from 80 to 85 dozen eggs.

Use infertile eggs preferably, and preserve within 24 hours after laying if possible. The fresher the egg, the better the result. Use clean eggs, but do not wash them.

A five gallon jar will hold about 15 dozen eggs. Sterilize the jar with hot water. Mix the water glass with water that has been boiled and then cooled to an ordinary temperature. some receipes call for one part of water glass to nine parts of water. A proportion of one to 14 has been found to be successfu, and is cheaper. Be careful to mix thoroughly, since failure often comes from careless mixing. If the jar is about half full of the diluted water glass, a few eggs may be added each day until the jar is full. Have about two inches of water glass above the top layer. Keep in a cool, dry place like a preserve closet.

CANADIAN EGG LAYING CONTEST

The Egg Laying Contests throughout the Dominion are attracting considerable interest. Already the entries are being rapidly filled by birds from all classes of poultry breeders. The fancier and the commercial man are being represented as are also the backyarder and the farmer, the old breeder and the amatur. Canadians are not going to have it all their own way either for both the United States and England are going to be represented.

The Dominion Experimental Farm is conducting no less than seven contests this year reaching from Prince Edward Island on the East to Alberta on the West. At Ottawa will be held the "Canadian" open to the world. Other contests will be conducted at six of the Branch Farms throughout the Dominion. The farms selected are Charlotteown, P.E.I.; Nappan, N. S.; Cap Rouge, Que.; Brandon, Man.; Indian Head, Sask., and Lethbride, Alta.

All contests start November first and continue for 52 weeks. Application must be made to Dominion Poultry Husbandman, Experimental Farm, Otawa. The time of receiving applications has been extended to October 15th.

MANGELS AS GREEN FEED

Mangels make one of the best winter "green" feeds for poultry. They are easy to store in any place suitable to the storage of other vegetables. Pits are good, but are often hard to get at when the ground is frozen. A root cellar is best. When to be fed, the mangel should be split or cut and hung on a stout wire just above the heads of the fowls so as to encourage exercise. It is better to give only what will be eaten up clean each day rather than to clog the fowl's appetites by having too much and having part spoil or freeze.

If you are not raising good chickens don't blame the birds, but find out where you are at fault.

Fashion Favors These Amherst Styles

With their graceful lines they possess a definite and dignified air of distinction that has won for them an enviable reputation in fashionable circles.

This good name is further enhanced by reason of their unusual wearing qualities.

Your shoeman will be glad to show you the newest Amherst models.

Amherst Boot & Shoe Company Limited, Amherst, N.S.

Heart and Nerves So Bad

Walked Floor All Night.

Nature intended women to oe strong, healthy and happy as the day is long, instead of being sick and wretched. The trouble is that they pay more attention to the work they have to do than to their health, therefor they become run down, weak and miserable. Milburn's Heart and Nerve Pills are the remedy that these nervous, tired-out, weakly women need to restore them to perfect health and happiness.

Mrs. Fred Lee, Almonte, Ont., writes: "My oldest daughter was so bad for over a year, with her heart and nerves that she was compelled to give up her work. I was very discouraged about her, as I had her to two doctors, but they did her no good. She could not sleep at night; would have to walk the floor, and felt as it she would go out of her mind. One day a friend told me to use Milburn's Heart and Nerve Pills, and I cannot speak too highly of them. She used three boxes and is feeling fine. She started back to work two months ago."

Milburn's Heart and Nerve Pills are 50c. a box at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

LEG WEAKNESS IN CHICKENS

Leg weakness in chicks may arise from more than one cause. One of these may be improper feeding. Another is keeping them too warm. Another is bottom heat in a breeder. Contrary to general opinion, chicks are not very delicate under natural conditions. I have known a hen to lead chicks through snow up to their bodies. Where hens steal their nests and hatch, the chicks get to the ground the first thing after they leave the nest. Little chicks should be kept where they can run on the bare ground at least a part of the time. They need sunshine also an da chance to get out in the open air.

We have never taken any particular pains to keep our chicks very warm. From the very first they are allowed to run out of doors as much as they wish. When they are raised in brooders they can have an outdoor run where they can get to the ground, and are out every day unless the weather is story. It is a pretty cold day when when chicks will not run out a good part of the time. If they get cold they run into the brooder and cuddle around the tank, but not longer than until they feel warm again, when they will be out digging in the chaff in their open run.

Well-fed chicks can endure quite cold weather and thrive. For many years we have fed prepared chick feeds and milk to our chicks with perfect success. Last spring was not a very warm one with us. We did not use incubators last year, and we allowed the hens that had chicks to run out with their broods every day after the chicks were four or five days old. If we lost as many as half a dozen chicks during the whole season we never discovered the fact.

We use prepared feeds because they are carefully mixed and made up of a larger variety of grains than are available with us.

At one time I made my own feeds. Taking the tables of feed analyses that I found in farmers' bulletins I found that a mixture of 45 pounds of cracked corn, 45 pounds of cracked wheat and 10 pounds of meat-scrap made a perfectly balanced ration for young chicks or laying hens. For two o rthree years I used this. We are now using prepared foods, and we have never found any difference in the feeding value of the different feeds.

We give our little chicks milk from the first day, all they will take. Sometimes the milk is sweet and sometimes sour, and sometimes it is buttermilk. We give them grit from the first and about our place there is always plenty of oyster shell lying where all the fowls can get it. We feed meat-scrap al lthe time to all our birds, old and young, and usually have a hopper full of bran where it can be got at. No matter how well fed a flock of little chicks may be, they will dig and scratch all day around the grass roots if they are allowed to run out. I have never been able to determine what they find that keeps them busy and have sometimes thought they pick up minute bits of sand. Whatever it is, they keep picking and digging and the exercise is certainly good for them. A good many young chicks are killed by mistaken kindness.

MILLER PURVIS.

CHICKS FIRST FEED

Much of the trouble often found in brooding chicks is due alone to feeding too early, or in excess during the first few days. In nature's way of brooding very little feed is secured by the mother hen for the first two or three days. Just here and there a weed seed, a morsel of tender grass, or, perhaps a worm. The chicks are contented, for they are almost continuously hovered by the mother hen, because natural instinct tells her that her babies should be carefully brooded until they have become strong enough to chase about. This, usually, is at least two or three days. But with the brood of chicks in the brooder it is natural for the attendant to wish to see them picking at the feed so easily scattered, and, fearing lest they should become hungry, in nearly every case they are fed too much at the beginning. We have never known a brood of chicks to be damaged from withholding the feed.

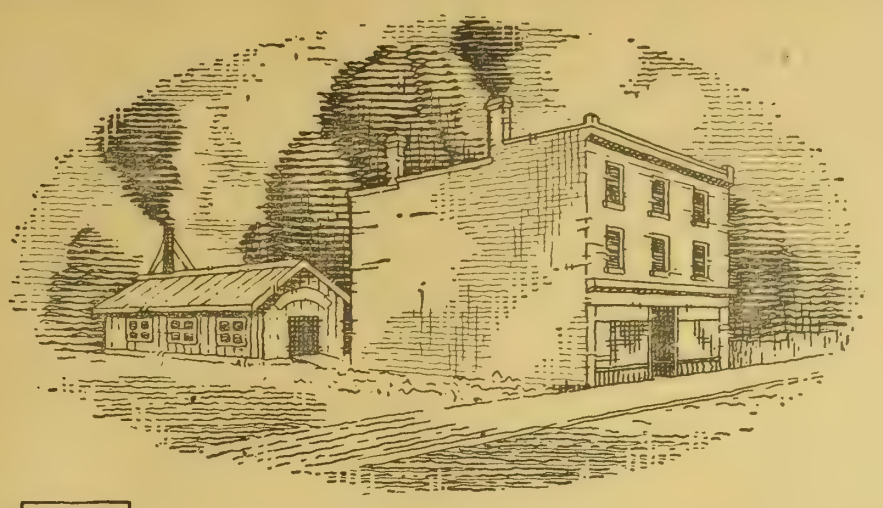
MARKET THE COCKERELS

Poultry keepers will find it more profitable to market young cockerels when they reach a weight of 2 lbs. rather than to feed the birds until late fall or early winter. Experiments show that at least 10 pounds of grain must be fed to produce a pound of gain and it is doubtful whether grain should be utilized for meat production through poultry.

On the average the feed necessary to grow birds to maturity will cost four cents a pound; thus unless the poultry producer has a special market for the heavier birds the price secured next fall may not pay for the feed given the fowls. Young cockerels marketed now as broilers generally bring an attractive price; then the flock may at once be fed with a view of developing winter-egg producers.

SKIM-MILK IS GOOD FOR CHICKS

According to on Ohio Experiment bulletin, the value of skim-milk as a food for growing chickens cannot be overestimated nor its cheapness and efficiency questioned. The reason is that skim-milk is a complete food in itself, and contains all nutrients in an easily digested form, which is very important for young growing animals. It promotes growth and insures a heavier increase in weight in a given time than could be otherwise obtained.



THE business that started so courageously in this humble structure in 1847, to-day dominates the stove and furnace business of the British Empire.

From the small number of quaint wood stoves made in those early days the output has grown steadily until now—it comprises

Thousands of Furnaces
in many styles and sizes and burning wood, coal or gas.

Cooking and Kitchen Utensils
in infinite variety and in such vast quantities as would alone constitute a great industry and

100,000 Stoves
using every practical form of fuel—electricity, gas, oil, coal and wood.

This success—this healthy growth over such a long period of years—could come only from fair dealing with the people. On any question regarding heating or cooking appliances, what better source of advice could you seek than McClary's.

Any of this list of Booklets on heating or cooking will be sent, if you mention this paper.

"Service from the Kitchen"—About the Kootenay Steel Range.

"Magic of the Pandora"—About the Pandora Cast-Iron Range.

"Comfort in the Home"—On heating with the Sunshine Furnace.

"Satisfaction"—Dealing with McClary's Gas Ranges.

"McClary's Electrical Appliances—On cooking with electricity describing McClary's.

"Household Helper"—Describing Florence Automatic Oil Cook Stove.

"The Story of a Range"—McClary's Simplex Combination Coal and Gas Range.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N B. solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

What is the grandest work of all—
Is it winning Heaven some day?
No. and a thousand times say no.
It is making this old world thrill and glow
With the sun of love until each shall know
Something of Heaven here below,
And God's "Well done!" for our pay.

JANET GROWS UP

(By Montayne Perry)

"You're quite sure you're through with the paper I want to talk to you," said Janet, "but don't let me hurry you."

Frederick Reeves flung the sporting edition to the floor, and surveyed his wife amusedly.

"Do I detect a tinge of irony in those last words?" he asked. "I've been only fifty minutes over that paper—and when you think of the number of yards of printed matter in a Sunday edition, that's not so bad. Oh, but I love the Sabbath day, Janet: late breakfast, and a house-coat and laziness and—you."

"That's an artful finish," declared Janet, "but as I said before, I want to talk to you."

"Oh, very well," resoignedly. "Of course a husband and father must expect to bear some responsibility, as you remarked the other night when the electricity went off without warning. Is this something that I'm as much to blame for as I was for that unilluminated evening?"

"Don't be silly," she laughed. "This is nothing you've done, or failed to do—it's about me."

"Then I'm interested!" he affirmed promptly. "Out with it—why keep me in this agony of suspense, woman?"

To his surprise her laughter did not respond. She perched herself on the arm of his chair, looking down at him with eyes that were wistfully serious.

"Fred," she began, "what was there about me that you loved, at first? Why did you fall in love with me?"

"Because your hair was curly!" he respondeed without a second's hesitation.

"Oh, but that isn't a reason—you don't love a girl just for curly hair!"

"You don't continue to love her just for curly hair. But you fall in love with her for exactly that reason—curly hair, or dimples, or the way she wrinkles up her nose when she laughs. Of course, love won't abide unless the girl's character has—has curls and dimples."

"And wrinkles!" she finished scornfully. "Well, then why did you continue to love me?" Without waiting for a reply she went on, rather breathlessly, answering her own question: "It's because your mind's in a rut—that's why. I'm—I'm just a habit!"

"A habit. Heavens, Puss, don't speak of yourself in that tone, as if you were some sort of a drug. What's it all about?"

"I ought to be doing something—broadening out, and keeping up with you," Janet declared, brushing away his levity with a little impatient gesture. "I shoud be making a place for myself in the world. 'Frederick Reeve's pretty wife' is what folks call me."

"Well, it's what you are. What's the matter with that? Don't you want to be my wife? Isn't that occupying a perfectly good place in the world?"

"Being your wife doesn't give me a place in the world, or it shouldn't. Being a wife isn't a profession, it's a—a—condition. Is being a husband your work in the world? Then why didn't you give up the practice of law when you married me? How would you like to be called just Janet Reeve's handsome husband? I've got to be an individual, an—an economic factor!"

"For the love of Mike!" Reeves murmered inelegantly. He stared up into his wife's pretty face, with unaffected wonder. "What's that, Puss? An 'economic factor'? Now where did you learn such expressions, young lady? You've been reading something!"

"Well, why shouldn't I read something? Do you think I have no b-b-brains? To his utter consternation her voice broke in a sob.

Swiftly he gathered her in his arms kissing the wet eyes, smoothing the beloved curls contritely. "I didn't know it was serious, sweetheart," he soothed. "Now begin all over again. What's happened to upset you like this?"

"It's been coming on for quite a while, I guess," she confessed. "You see, it's in the very air now, all this talk about woman being independent and making her own place in the world, and holding a man's affection because she can do the same thing he can, and not being just a Mrs. Somebody. And, of couse, I always read Molly's magazine, and that's full of new-womany stuff, and altogether I've come to see that I'm not doing what I ought to do, really, dear. I should be standing on your level."

"Heaven forbid!' interpolated Frederick fervently, but Janet went on, regardles of the interruption: "So I've thought it all out, and I know just what I'm going to do, and it needn't interfere with our home in the least."

Through the man's mind danced visions of Janet as a feminist; Janet bent on studying medicine, maybe, or or law, or going in for politics, Janet with an office in town, rushing for the seven-fifteen with the commuting mob; Janet in tailored suits and stiff linen waists, swallowing her breakfast with one eye on the clock, instead of dallying over her coffee in distracting negligee; Janet and business—could anything be more incongruous?

"I'm going to be a writer, because I can do that at home—I'd hate going to town every day. I shall keep office hours, and tell Marie never to disturb me except for something of life-and-death importance—like Junior swallowing a button or having croup. Writing is a dignified profession and one of great financial possibilities, and lifts a woman far above the petty details of every-day life," her voice became a bit stilted on the last words as if she were quoting "Molly's magazine."

A vast relief flooded the husband's soul. A writer with a studio at home! The disquieting visions fled. Instantly there sprang into action the tact the broad vision, the ability to understand and to guide human emotions which had placed Frederick Reeves in the front rank of the legal profession. A lesser man would have told Janet that home-making was a dignified calling and that the bearing and training of Frederick, Junior, established her status as an economic factor; that her busy, happy, love-filled days were far from fruitless; but none of these things did he suggest. He patted the curls and cried enthusiastically:

"The very thing! Let's fix up your studio right now! Then you can begin to-morrow morning."

"Oh, Fred—you're the darlingest! Do you think I can write?"

"Why not? Look at Molly! Aren't you her sister?"

"Oh, but Molly's so clever. And she's always been doing things, you know. I'm perfectly sure she will say I can't write."

"We'll show her!" he declared. "If she discourages you, we'll sell your first story to her deadliest rival!"

For an hour they worked in the big room on the top floor, until rugs, desk, books, pictures, even pens and blotters were in proper places. Then, as Janet hurried away to her small son, Reeves went into the library. He closed the door carefully before he lifted the telephone receiver.

"Hello," he said presently, "that you, Molly? You're coming to dinner, aren't you? Well, I just wanted to tip you off, before Janet springs anything on you—see? She's got the queerest freak! Been reading your magainze too much, I guess. Janet has decided to become an economic factor—her self-respect demands it. What's that? Well, it's your own fault. She's going to be an author. What? No, you mustn't settle that—you'll agree to it—get me? Where's your judgment? Don't you know that opposition is meat and drink to a woman's hobby? That is a perfectly safe and sane proposition, one that she can play with at home, all safe and comfy, until it wears itself out. All right—'by."

"She wants to write!" she murmured. "Janet wants to be an author! Now what does the child think she could write about? What does she know about life? Didn't I guard her from everything until Fred took the job off my hands? But hasn't he a lot of tact and judgment—for a man! Of course his plan is right. Let her little flurry of ambition die its natural death."

So when Janet rather tmidly approached the subject of her heart's desire that evening, she found, to her surprise, that her gifted sister was something more than sweetly sympathetic; she was distinctly encouraging.

"You're just a dear," Janet declared, with joyous relief. "I thought you'd try to squelch me. I expected you to say, 'Why can't you be satisfied with your home and Frederick and Junior? That's enough for you to do.' For you know, Molly though you do print all those things about women having economic independence, you've always made just a regular old-fashioned clinging vine of me."

Molly colored a little, hearing Freds appreciative chuckle. Inwardly, this clever and efficient young woman was always conscious that Mary Slade Mason, editor, was a distinctly different person from Molly Mason, sister—but she was surprised to hear Janet voice a knowledge of the fact. She spoke quickly to cover her confusion:

"I quite understand, dear. You've been married five years, and Junior is three years old, so you have had time to get your home affairs to running smoothly. Having a maid and a nurse, you find yourself with a lot of unoccupied time which might as well be put to some real purpose."

"And you think I can write stories?"

For an instant, Molly the sister, struggled with Mary the editor. It was a sisterly answer tempering of editorial judgment:

"Of course you understand that it takes a lot of work, and practise, to produce anything which is salable. I don't believe I'd try stories just at first—short stories are the most difficult things to write, you know. One has to work up to them."

"But I certainly couldn't write anything except stories, Molly. I'll have to write about men and women and—and—oh experiences, you know. Marriage problems and things like that."

"But those stories are written by folks who have some knowledge of life's problems. You know, Janet, you've had no real experience with the big issues of life. One has to know about things in order to write convincingly. But I wouldn't bother about that part yet. When you have learned to tell a story, you can decide what particuar kind of things you will do."

"I thought the way to tell a story was just to tell it," stated Janet, a trifle rebelliously.

Molly's ready laughter cleared the air, "I wish all my contributors thought the same thing, little sister," she declared; and the discussion closed amicably.

Mary Slade Mason, editor, began on a heap of unread manuscript with a sigh. She glanced at the opening sentence of one, turned to the end and

ALL SUMMER COMPLAINTS

SUCH AS

Diarrhoea, Dysentery, Colic, Cholera, Cholera Morbus, Cholera Infantum, etc.,

ARE DANGEROUS.

During the hot weather the bowels seem to be more susceptible to disease than at any other time of the year.

The holiday season is on; you go travelling and change your diet and drinking water; catch cold at every change in the weather; eat unripe fruit, etc., which causes the bowels to become loosened up. To get relief from these conditions, you must take something to relieve those awful cramps in the stomach; those awful pains in the bowels; in fact, something that will in a natural and effective way stop the fluxes of the bowels as quickly as possible, and at the same time not leave them in a constipated condition.

Dr. Fowler's Extract of Wild Strawberry is exactly the remedy you need, and by using it you are not taking any chances to endanger your health as it has been on the market for the past 74 years, and we have yet to hear of one instance where it has not done everything we claim for it.

We wish to warn the public that a great many instances have been brought to our notice where dealers have been asked for "Dr. Fowler's" and have tried to sell a substitute. Protect your health by not accepting substitutes for this old and tried remedy; they may be dangerous.

Price 35c. a bottle at all dealers. See that our name appears on the wrapper. The T. Milburn Co., Limited Toronto, Ont.

skimmed the last page; threw it down with a gestture of hopelessness. The next met a like fate, and the third, and the fourth. But on the fifth one she re-read the last page, dipped into the middle for a paragraph or two, and turned back to the beginning and read the whole slowly.

"There's the feature story for my fiction number!" she exclaimed. "It's the best thing that has fluttered in here this year!"

LET a woman ease your suffering. I want you to write, and let me tell you of my simple method of home treatment, send you ten days' free trial, postpaid, and put you in touch with women in Canada who will gladly tell what my method has done for them.

A MESSAGE TO WOMEN!!

If you are troubled with weak, tired feelings, headache, backache, bearing down sensations, bladder weakness, constipation, catarrhal conditions, pain in the sides, regularly or irregularly, bloating, sense of falling or misplacement of internal organs, nervousness, desire to cry, palpitation, hot flashes, dark rings under the eyes, or a loss of interest in life, write to me today for free trial treatment.

Mrs. M. Summers, Box 309 Windsor, Ont.

Minard's Liniment Co., Limited.

Dear Sirs,—I had a Bleeding Tumor on my face for a long time and tried a number of remedies without any good results. I was advised to try MINARD'S LINIMENT, and after using several bottles it made a complete cure, and it healed all up and disappeared altogether.

DAVID HENDERSON,

Belleisle Station, Kings Co., N. B., Sept. 17, 1904.

The phone beside her whirred sharply.

"Yes—who? Oh, Mr. Reeves? Certainly, send him in."

"What's happened to bring you away from the office at this hour?" was her greeting to her brother-in-law, a moment later. "There's nothing wrong at home?"

"No. That is, nothing really wrong, but I feel a bit uneasy about Janet. No, she's not ill. But this story writing is getting on my nerves."

"I thought that had died a natural death. She hasn't mentioned it to me for weeks.'

"Nor to me—that's just it. She writes and writes and writes. Hannah says she spends six hours up there in her studio every day. And she doesn't say a word about it. I'm afraid she's laying up an awful disappointment for herself."

"Writing a book, I suppose—and imagining it a best seller!" Molly laughed, but her eyes were both tender and worried. "Well, I don't know what we can do. You wouldn't let me discourage her in the start, you know."

"I know. And now I can't bear to think of her working so hard all for nothing. Molly, you couldn't buy a story of her, and then have it fixed up and print it with her name——"

"I could not!" snapped Mary Slade Mason, editor. "Anyhow, can't you see it would only make things worse? She'd write them by the dozen after that."

"I'll tell you," he said finally, "you must do a lot of talking in Janet's hearing about how difficult story-writing is, and how long it takes to get anywhere, and how exacting magazines are."

"Which is all quite true," she finished. "I've gone through more than a hundred manuscripts this week hunting the story I wanted, and I discovered it just as you came in. It's a real find."

"Why not bring it over tonight and read it to us," he suggested. "It might give Janet an inkling of how far she has to climb."

So Molly Mason went to dine with her sister with the favored manuscript tucked away in her bag. Dinner was over when she mentioned the story.

"Such a fine story came in today," she said, with careful carlessness. "It's in my bag—maybe you'd like me to read it to you?"

"Yes, do," said Janet eagerly. "Is it a love-story?"

"A story of married love—a problem story, but an unusually good one. Wholesome and sane and humorous, yet it goes straight to the heart of one of the biggest things in life."

"I suppose it is by a very famous writer," said Janet.

"No—in fact it is signed with a name which I never heard before. I'm quite curious about the writer. She must be new in the fiction field."

"Begin," said Janet; I'm so anxious to hear it." She curled herself up in a great leather chair, looking absurdly childish in her soft white dress.

It was a simple story of a wife who met, faced and finally conquered one of the delicately complex problems which all wives encounter. It brought to a world-old theme the light of sane, modern thought, flecked here and there with dashes of whimsical humor.

It was after one of these bits of humor that Reeves straightener himself suddenly, and began to stare at his wife. But Janet's head was bowed on her slender hands, and she was apparently absorbed in the story. Molly read on.

" 'A man falls in love with a girl because of her curly hair, or her dimples, or the way she wrinkles up her nose when she laughs—' " read Molly, and paused in astonishment as Reeve's joyous shout filled the room.

"Janet! You little wretch—you imp!" Somehow, he was occupying the big chair with Janet, laughing and blushing and sobbing, all at once, settled firmy on his knee, her radiant face held in the hollow of his hand, while he stared at her with eyes full of pride and wonder. "Why didn't you tell me?"

"I—I was going to wait until it came out in the magazine. I—I thought you and Molly'd be surprised."

"What—what—I don't know what either of you are talking about!' declared Molly. "Have you both lost your senses?"

"Madame, Editor," said Frederick Reeves, rising and leading Janet to her bewildered sister's side, "perimt me to introduce to you the author of your wonderful story. I suspected it before you'd read three pages; I felt sure of it when you reached that part about the kid with the croup—and when that sentence about the curly hair came out I knew it!"

But Molly was staring at her little sister as though she had never seen her before.

"Janet!" she gasped, at last. "How could you? How could you say those things—how could you think them—how could you know them? You've had no experience——"

She broke off helplessly, and Janet looked at her with a new expression—a look of mingled affection and amusement and tolerance.

"After all," she said sweetly, "you know I am twenty-seven years old; and I have been married five years, and I have borne a child, and brought him through his three years of babyhood. Just what do you think life's great experiences are, Molly?"

"Why, little sister—you're—you're grown up!" stammered Molly dazedly.

OPEN KETTLE CANNING

The old fashioned method of canning, especially of fruits and tomatoes, was by the open kettle methor. This consisted of cooking the fruit in an open kettle, transferring it, boiling hot, to a sterilized jar and sealing it immediately. Mould frequently appeared on the top of the jar often causing complete loss. Bulletin No. 93, Preservation of Fruit and Vegetables for Home Use, which may be had on application to the Publications Branch of the Department of Agriculture at Ottawa, states that foods decompose or spoil because they are attacked by living germs which are minute forms of plant life. Three types of these tiny organisms cause the spoilage in foods,—moulds, yeasts and bacteria. Every household is familiar with moulds in their growing satte. They thrive in dampness and darkness, require moisture and warmth, and feed upon sugar and starches. Moulds are easily killed by moist heat, and when the open kettle method of canning is used the jars should be sterilized at least ten minutes after being filled.

New Brunswick Lady Tells of Dodd's Kidney Pills

She Says They are the Best Medicine For Lame Back and Advises All Persons Troubled With Weak Kidneys to Use Them.

McGivney Junction, York C., N. B., Sept. 29th, (Special)—From all over New Brunswick reports are coming telling of the continued popularity of Dodd's Kidney Pills as a remedy for all forms of kidney trouble. No place appears to be too small to furnish at least one person who is prepared to say that she owes her health to the great Canadian kidney remedy. Miss Carrie E. Ferguson, a well-known resident here, is one of them.

"I am happy to say that I found a great improvement in my health after using Dodd's Kidney Pills," Miss Ferguson states. "They are the best medicine I can find for lame back. I advise anyone who is troubled with weak kidneys to try them. I tell everyone that Dodd's Kidney Pills are good."

Dodd's Kidney Pills have become a family remedy all over the province because people have tried them and found them good. They are purely and simply a kidney remedy. They help Rheumatism, Lumbago, Diabetes, Lame Back, Heart Disease and urinary troubles because all of these are either Kidney Diseases or are caused by the kidneys failing to do their work.

LAMPS

For perfect lamp light, the first requisite is good lamps; those with central-draft burners are far and away the best. The student's lamp with the Rochester burner is as near perfect as anything likely to be made in lamp shape. The price of such a lamp runs all the way from two and a half to twenty dollars. The difference is one of finish and ornamentation. Choose a lamp with a broadish solid base rather than one top-heavy, and given to oversetting. Look also at the size of the burner; unless it is big enough to hold without packing a good sized wick, the lamp will give a poor light. The oil reservoir had better have no other opening than that which admits the wick. Those with a special cap for pouring in oil are convenient, and, in careful hands, safe. But the mas of folk are in dange rof being tempted by them to fill up a lamp already lighted, or else to leave wck and burner for so long undisturbed, both become clogged and gummy.

Do not let a lamp stand with a little oil in the bottom. Do not even light one that has stood partly empty for a week. The best oil vapourises under some conditions, and the vapor is highly explosive. Every burner ought to be supplied with an extinguisher, but where the extinguiser is lacking, do not blow down a chimney to put a flame. Especially not if the lamp has been burned for several hours. Ninety-nine times in the hundred the lamp may come in contact with gas and do no end of damage.

Turn down a lamp flame one-half before moving it from one room to another. But do not leave it low enough to smoke or smell. It will do both if left with flame showing dim. If the light must be moderated, either take the lamp outside or shade the flame, half-shrouding it, rather than turning it too low.

The vtal thing about a student's lamp is to set and keep it level. If the oil-tank is for even a minute a little higher than the burner, the burner will be overflowed, with disastrous results. In filling such a lamp, be sure not to leave air-bubbles upon the top of the oil. Such bubbles have a knack of choking up the narrow supply pipe, and making the light dim and yellow.

Next to good lamps comes good oil, properly kept. The best oil is as white and clear as spring water, and will evaporate after a while, leaving no stain.

Oil keeps in glass, at a temperature between fifty and sixty degrees. Tin cans are light, but in steady use given to springing a leak at the most inconvenient seasons. There is a glass oil-can in an open-work tin holder, with bail and handle, and coming in various sizes, that answers admirably in careful hands, or where it has only to go to the corner grocery for filling. Folk who must fetch home their oil supply in a farm wagon, and presumably over rough roads, will find nothing else quite so good for holding it as a five-ballon demijon, with its wicker work still staunch. The demijon is of manageable size, does not overset nor break easily, and never, never leaks. With reasonable care it will last a life time, and still be a heritable asset.

Get the very best wicks, soft, or loose, rather coarse mesh, and big enough to fill the burners without any crowding or packing. A wick too small admits air into the oil-tank, thus setting up vaporisation. Further, it leaves a space for the passage of flame downward is a lamp is improperly blown out. The proper way, be it said, is across the flame, not from over head. Buy, in bunches, wicks of sizes to fit every lamp in the house. Put all the bunches in a porcelain kettle, cover them with strong ivngear, bring the vinegar to a boil, and set where the kettle will keep warm for three hours. Drain out the wick buiches, dry thoroughly, and keep away from dust. Wicks thus soaked and kep tclean, both before and aftef going in the burner, almost never smoke. In use trim the wicks once a week, but always very lightly and evenly, taking off the snuff—the burned part—but never any charred wick. Some excellent housekeepers, indeed, never put scissors upon a

Bottle Cleaner—Baby Healthier

Read what the maker of a famous baby-food has to say:

"Simply rinsing feeding bottles in water will not do. As soon as the meal is finished, the bottle should be rinsed with hot water and Gold Dust, *otherwise the fatty constituents of the milk cannot be removed from the inside of the bottle.*"

But—be sure it *is* Gold Dust you buy. The name FAIRBANK'S and The Twins are on every package.

Real home-made preserves, and the woman who puts them up—how they're both appreciated.

Preserving is not difficult to-day. The LILY WHITE way has removed the uncertainty.

Most of your preserving troubles have come from using sugar alone. Even the beginner can count on success if she will use half LILY WHITE and half sugar. LILY WHITE blends the sugar with the fruit and makes preserves that will never crystallize.

LILY WHITE and CORN BRAND are both Dandy for Candy.

Your grocer sells Crown Brand and Lily White Corn Syrup in 2, 5, 10 and 20 pounds tins.

LILY WHITE *Write for Booklet on Receipes* **CROWN BRAND**

wick. Instead they turn the wicks up an inch, then, with a coarse cloth held over thumb and forefinger, rub and pinch off the snuff. Whether cut or pinched, the main thing is to leave the wicks withouot tag ends or jagged places. Tag ends and jags mean always smoked and broken chimneys.

There are chimneys and chimneys—all breakable. ome are supremely so in the hands of the average maid-servant. Luckily they are also cheap; especially when bought by the dozen or the gross. If all the lamps of the household take chimneys of the same size, the gross is possible, and a sensible economy. After buying thus in quantity, put some hsavings in the bottom of a wash boiler, pack the chimneys snugly wodn in it, stew a handful of salt over them, then almost fill the boiler with cold water, and set it where it will come very slowly to a boil. Let it simmer for two hours, then take from the fire and cover so thickly it will be at least three hours in cooling. When it is cold, wash the chimneys in clear hot water with a suspicion of soda in it; rince, also in hot water, wpe dry, and store on the hghest shelf in the closet. There the warmest air in the kitchen will still further toughen them. Nine chimneys in ten break through unequal heating. Boiling this way, and keeping it a warm place afterward, seems to effect some molecular change which makes the glass much less liable to break.

Boil all the movable metal parts of lamp burners once a month, rinse well with boiling water, and either dry in eth sun or on top of a hot stove. If the burners are clogged and gummy, scour them lightly before putting on toil. A clean burner is nearly as essential to good light as a clean chimney. Wash the chimney also in hot soda water, rinse well, wipe dry, and polish with crumpled newspaper.

For filling lamps one needs a small glass funnel and a length of glass pipe open at both ends. et the funnel in the lamp-mouth, and pour in oil steadily until it comes in view at the bottom of the funnel. If by chance it stands so high the wick would make it overflowing, plunge the glass tube down inside the funnel, clap a finger over the open end, and draw it back. The surplus oil will come with it, and may be held there by keeping the finger in place until the funnel is shifted. Lamps burn better for being full, but should not be too full; invariably then the oil oozes all over the top, and eithe runs down on the foot or vaporises, and makes the whole room smell.

HOT BREADS FOR COLD DAYS

(By Mrs. Emily Grant.)

With the coming of frosty mornings, the fragrance of hot breads, mingling with the aroma of well-made coffee, gives a fillip to appetite.

Muffins or biscuit made with soda or baking podwer usually require about fifteen minutes for their baking in a hot oven. Muffins or biscuits made with yeast require from tyenty minutes to haf an hour in a moderate oven.

Cornmeal, graham, rye or wholewheat muffins take from five to ten minutes longer to bake than those of the plain wheat, which require intense heat to develop the sugary portions of the wheat.

It is usually considered best to put muffiins, biscuit and the other small breads on the bottom of the oven first so tha tthey will rise to their full height, then set them on the upper grate to finsh baking and browning.

Graham Gems

Sift together one cupful of graham flour, one cupful of pastry flour, two level tablespoonfuls of baking powder, a rounded tabespoonful of sugar and a salt spoonful of salt. Add three tablespoonfuls of melted butter, an unbeaten egg and a cupful of sweet milk or milk and water. Beat all together until smooth and "bubbly" on top. Grease a dozen muffin molds, your in the abtter and set in a slow oven until the muffins rise to the top of the pans, then increase the heat to brown and crisp them.

Corn Muffins with Sour Milk

Sift together one cupful of cornmeal, one-half cupful of flour, one-half teaspoonful of salt and three-quarters teaspoonful of soda. Beat one egg thoroughly, add to it one and onehalf cupfuls of sour milk, and combine with the dry ingredients.

Add one and a half tablespoonful of butter or shortening melted, mix thoroughly, then pour in hot, well-

Spanking Doesn't Cure!

Don't think children can be cured of bed-wetting by spanking them. The trouble is constitutional, the child cannot help it. I will send **FREE** to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatment is highly recommended to adults troubled with urine difficulties by day or night. Write for free trial treatment.

greased pans and bake twenty-five minutes in a moderate oven.

Rice-Flour Muffins

Sift together one and one-half cupfuls of rice flour, two cupfuls of wheat flour, half a teaspoonful of salt and a tablespoonful and a half of baking powder. Add one pint of sweet milk, a tablespoonful of melted butter and a well-beaten egg, beat smooth and bake in gem-pans or muffin rings.

Hominy Muffins

Take a cupful of warm boiled hominy cooked to the proper consistency for breakfast mush and mix with it a tablespoonful of butter, a half teaspoonful of salt and a cupful of milk.

Sift together a cupful and a half of pastry flour and teaspoonful and a half of baking powder and add gradually to the hominy mixture. If the boiled hominy is rather thin, a little more flour may be needed.

Lastly, add two well-beaten eggs and bake in a hot oven for half an hour.

Breakfast Bread

Take four slices of baker's bread, cut off the crust and lay them in a pan; pour boiling water over them, just enough to soak them, then cover When the bread has stood for an hour drain it and stir until it is a smooth mass; add two tablespoonfuls of sifted flour and half a pint of milk. Beat two eggs and stir them into the mixture gradually. Grease some muffin-rings and place them on a hot griddle; fill them and bake brown.

Serve hot and break open to butter.

STORING APPLLES FOR WINTER

Most farm families are now laying in a stock of apples for winter use. It is one of the best and most approved customs of rural life. There are very few families, however, that find themselves provided with strictly modern refrigerated storage houses. Most of the apples kept for home use muse be held in storage of a more or less makeshift character. ome of these substitutes are good and some very inefficient. The commonest home storage place is the cellar under the dwelling house . This may be a very good apple storage or it may be almost worthless. It should be cool and moist, not warm and moist. If it is cold enough it is hardly likely to be too moist. The cooler the better, too, up to the point of actual freezing. The ideal apple storage should maintain a uniform temperature as near as possible to 32 degrees. The great majority of house cellars are too warm. For this reason a shed room, the granary or an old harness room is often better than the cellar.

The old theory was that the apples should be put on shelves or trays in shallow layers and frequently sorted, those which were beginning to decay being removed as soon as possible. The fruit is better off if it is not handled at all during the storage peroid. It can be placed in bushel boxes or in barrels. If in barrels they may be headed up or left unheaded.

Regulating the Temperature

Other substitutes for storage besides the cellars are well worth considering. It was the old custom in certain neighborhoods to store apples in the haymow, and if the mow keeps a temperature steadily near the freezing point the results are bound to be excellent. A still older practice consists in burying the apples in pits. This also is a good substitute storage if properly managed. The pit should be dug in a gravelly, well-drained spot and perfect drainage away from the pt provded. It may be arranged to hold any quantity from ten to one hundred bushels of fruit. The pit is lined with clean straw or even hay and the apples piled in and heaped up into a tall cone. They are allowed to cool thoroughly with the coming of fosrty nights. Along in November, when there is danger of actual freezing such as would spoil the fruit, a layer of straw is covered evenly over the whole. As the cold increases this straw covering is reinforced with a thin layer of earth. This earth covering is not put on all at once; the botom of the cone is covered first, leaving the residue of heat which the apples contain to pass off through the apex of the pile. The top is finally covered, however, and the earth protection is gradually thickened by putting on successive layers. By the time the ground freezes up so as to stop these preparations the apples are thoroughly cooled and the pit is sufficiently covered to last through the winter.

On godd, well-provded, up-to-date farms regular fruit storage rooms should be constructed. These need not be provided with artificial refrigation, but must be free from the varying and uncertain influences of the common cellar. They require chiefly good insulation for the walls and good, easily controllable ventilation. The ventilators are opened at night and closed during the day. This cools the fruit down until the freezing point is approached, when the ventilators are kept closed all the time; or if there is danger of freezing the fruit the process is reversed, the ventilators being opened during the warm days.

SWEEPING

To sweep a carpet which is not to be taken up house cleaning time, sprinkle the floor well with clean sawdust lightly damp. This, if it is matted or carpeted—rugs must be removed before dusting the walls. Sweep up the saw dust with a stiff broom wet in hot water, and washed clean as soon as it shows much dirt. Take up the saw dust and sweep again with a softer broom, barely dampened. If the carpet is not to come up, go over it after second sweeping with a cloth dipped in hot water and ammonia—a tablespoonful of ammonia to a quart of water. Wipe a yard or so at a time, then wash out the cloth in plain water, so as tot keep the ammonia clean to the last. The cloth is, of

Full weight of tea in every package

RED ROSE TEA "is good tea"

Sold only in sealed packages

121

course, dipped in it after washing and wrung as dry as possible.

The tidy house keeper always wears a dust cap on sweeping and dusting days, and before starting to sweep she should half raise the lower sash and put down the upper ones an equal distance, so that there is a good current of air circulating through the room, and instead of just "stirring up" the dust as is often done, the good circulation will carry away the dust. It is well to use moist dust cloths.

To avoid raising much dust when sweeping, besides useing damp sawdust, the housekeeper may sprinkle her carpets with scraps of dampened newspaper or moist tea-leaves. Some use slightly dampened coarse salt, but this is difficult to get thoroughly out focarpets and has been known to rot them when allowed to stay in them any length of time.

To properly clean a floor after the carpet has been removed, sprinkle the floor tackly wth cleaan, damp saw dust and sweep with a stiff broom. Take long, sweeping strokes and keep the broom low, so as not to raise dust. Follow the sweeping with a good washing. Do not splash water on the floor; it is sure to mar the base board, and likely to damage the ceiling underneath. Use a soft, coarse cloth, and warm water with a handful of soda in it, and finish by wiping with a cloth wrung very dry out of clear hot water. Dry the floor and air the room thoroughly . If possible to leave the room unoccupied over night, let the upper sashes of the windows stay open until twelve o'clock next day.

MOTION PICTURES OF MATAPEDIA VALLEY

While on the C. N. R. special train from Halifax to Quebec recently, carrying newspaper men and moving picture operators, who were following the Prince of Wales on his tour, some of the motion picture men secured views of the Matapedia Valley. They mounted the deck of the locomotive and operated their cameras while the train sped through the Morrisey Rock Tunnel and across the Restigouche Bridge. At a point beyond Matapedia station the train was stopped and several group pictures were filmed.

These pictures will be shown in connection with the news films of the Prince's tour.

HEAVY PASSENGER TRAVEL ON C. N. R. LINES

Passenger travel is remarkably on sections of Canadian National Railway Lines, and particularly so in the Eastern section where trains between St. John, Halifax, Sydney and Montreal are every day filled to capacity. The popularity of the Maritime Express and Ocean Limited is amply demonstrated by the many applications for sleeping car reservations on these well equipped through trains.

Requests for space are so numerous that extra cars are being caried and often trains run in two sections. With the rush of travel from troop steamers arriving at Halifax and Quebec this means considerable of a strain on the railway for equipment.

Passenger business which has been very brisk all summer, is likeyl to continue through the fall.

PARABLE OF THE SOWER

Up to Date

H. L. Krum, Deering works, found this parable in the Chicago Health bulletin, and intimates there may be something of interest to others, who may not be exactly aware of dangers in careless coughing.

1. Behold the cougher went forth to cough.

2. And when he coughed, some germs fell upon the sidewalk and the feet of the pedestrians came and gathered them up and carried them into their homes.

3. Some fell into nostrils that were hard and unfruitful and forthwith a slight cold appeared. It was not worse because there was much opposition to them on account of the sterility of the soil.

4. And when the sun was up these colds were scotched, and because they had no root these colds withered away.

5. And some fell in thorny places, such as those that have an immunity, and in this wise they were choked out.

6. But others fell into good ground for them, and brought forth much disease; some an hundred-fold, some sixty-fold, and some thirty-fold.

7. Who hath ears to hear let him hear and go forth to the health department and view the great harvest of pneumonia, tuberculosis, lagrippe and bronchitis, all of which is on record in the archives of the department.

8. Who hath ears to hear, let him hear that over 10,000 of our people were garnered during the year of our Lord 1917, from the seed of the cougher and sneezer, and now sleep with their fathers in their untimely sepulchres.

9. Be ye not of those who, having ears, hear not, and who, having eyes, see not those things which we have herein set forth that so nearly concern their temporal health and salvation.

10. Muffle the cough, smother the sneeze and expectorate not in public places to the end that divers and grievous disorders come not unto thee, nor unto thy neighbor.

12. And remember now the teachings of the health department that thy days may be long in the land which the Lord, thy God giveth thee.

Glad to know that the altitude record is held by an American aviator and not by the cost of living.

FERTILIZERS

It is now nearing the time when farmers will be placing their orders for their commercial fertilizer requirements for 1920.

There is no one subject of greater importance to farmers than the maintenance of the fertility of the soil.

Fertilizers should be employed in addition to and not in place of other good soil management practices. Legumes in the rotation, the use of manure or other organic matter, drainage and liming where needed are all prerequisites to the most satisfactory use of fertilizers.

The kind of fertilizer to use depends upon the soil type, the way the soil has been cropped and the system of farming practiced. It has been shown repeatedly that the conservation and application to the soil of all manures and crop residues and a more generous use of legumes to provide further supplies of nitrogen and organic matter, are practices of prime importance and should be foremost in any place of soil management. On some soils, however, these practices are not enough for maximum yields and something more must be done. Investigations by Experiment Stations and practical, progressive farmers have demonstrated that most soils aer deficient in one or more elements of plant food, and that generally some kind of a fertilizer may be used to advantage.

In the choice of fertilizers farmers have been confronted with such a vast array of formulas, mostly low grade, that intelligent selection has been made unnecessarily difficult.

Low grade fertilizers contain small amounts of plant food and usually made from low grade materials of low availability, have always been more expensive per unit of plant food contained than high grade mixtures containing large amounts of plant food of better quality. Rich mixtures must necessarily contain better materials of higher availability and will produce better results. The farmer who buys mixed fertilizer on the basis of low price per ton pays most for the available plant food he actually gets. The cost of mixing, transportation and handling of low grade fertilizers are all higher per unit of plant food contained than in the case of high grade mixtures, and the consumer has to bear the extra expense. Fertilizers should always be purchased on the basis of composition and quality, and not on the basis of price per ton.

All fertilizers should be bought and sold by formulas and not by brand. Brand names should not be used except in connection with the formula, so that there may be no confusion in the mind of the purchaser as to the composition of the fertilizer he is buying.

Fertilizer values are usually compared on the basis of price per unit of plant food contained. A "unit" of plant food is 1.0 per cent per ton. To calculate the price per unit, the price per ton should be divided by the per cent of plant food contained. Thus, for example, if it is desired to determine what 16 per cent acid phosphate selling at $24.00 per ton is worth per unit, divide $24.00 by 16, which gives $1.50 as the price per unit.

To determine the price of potash in an O-12-4 fertilizer, selling at $34.00 per ton, first deduct the value of the 12 units of phosphoric acid, which at $1.50 per unit, is $18.00. This leaves $16.00 as the price of the four units of potash. Divide $16.00 by 4 gives $4.00, as the price per unit of potash.

If, next, it is desired to know the price of nitrogen in a 2-12-4 fertilizer selling at $46.00 per ton, deduct first the value of the 12 units of phosphoric acid and four units of potash, which is $34.00. This leaves $12.00 as the price of the two units of nitrogen. Dividing $12.00 by 2 gives $6.00 as the price per unit of nitrogen. To get the value of plant food per pound, divide the price per unit by 20, which is the number of pounds in a unit. Thus nitrogen at $6.00 per unit is worth 30 cents per pound.

Any particular mixed fertilizer formula may be prepared at home in any desired quantity from fertilizer raw materials, which may be purchased separate, such as Nitrate of Soda, dried blood, acid phosphate, bone meal and various potash salts. Home mixing is advantageous where the raw materials can be purchased as is clearly set forth in a letter, the heading, "A Plumper for Home-mixed Fertilizer". The amount of fertilizer to use per acre will depend upon the condition of the particular field and the treatment given to preceding crops. On ordinary soils, enough phosphorus should be applied in the course of the rotation to return all of this element that has been removed in crops. In the case of the non-acid mucks, potash is the element most in need of replenishing. The fertilizer needs of clover and grass grown in rotation with grain crops should be provided for by increasing the amounts used on the grain crops. On soils deficient in nitrogen, wheat and timothy may often be profitably top dressed with nitrate of soda in the spring. This system is extensively followed by farmers in some parts of the Maritime Provinces.

Light colored soils are quite frequently deficient in organic matter and nitrogen. The only practical means of supplying the bulk of the nitrogen needs of crops on these soils is the production of legumes, which can secure nitrogen from the air, or the use of large amounts of manure. These soils require special and constant attention to their organic matter and nitrogen supplies and provision should always be made to have abundance of organic matter, especially legumes, to plow under. The black soils are relatively well supplied with organic matter and nitrogen, and seldom respond to nitrogen in fertilizer.

On acid soils, lime must be applied before the best results can be secured. It must be remembered, however, that lime cannot take teh place of fertilizer nor can fertilizer take the place of lime. Lime should always be purchased separately. Gypsum or land plaster is not a fertilizer nor a corrector of soil acidity. It is merely a soil stimulant and while it sometmes ncreases crop yields, it does so at the expense of the plant food already in the soil. By its use the soil will become poorer.

The most satisfactory results from the use of fertilizers will be secured when they are used in connection with otherwise good systems of soil management, including legumes in the crop rotation, the careful use of manures and crop residues, tile drainage and liming where needed and the practice of good cultural methods generally. Realizing the value of thorough cultivation in procuring good results in crop production, the farmers of the Maritime Provinces carried out last season, the most thorough systems of cultivation that we have ever seen practiced in Maritime Canada, and hundreds of them are wakening up to the lime requirements of their soils.

Aroostook Farmers Hot-Foot For Potato Tariff

In a recent issue of The Maine Farmer, Geo. V. Brown, Secretary of the Aroostook Federation of Farmers, heralds the good news to potato growers that the embargo on foreign potash has been lifted. This transpired through the efforts of the Federation, who urged through the American Senate, upon the War Trades Board the necessity fo rthe removal of the embargo. Mr. Brown points out in this respect the value of concerted effort. He says labor unions, have reached the position where they almost dominate political affairs by keeping men on the job all the time to look after their interests, and if the farmers are ever to get a square deal at their federal or local capitals, they must organize, and when they want anything, go after it.

In regard to a tariff on potatoes entering the United tSates, Mr. Brown says that the Federation has been assured that if the farmers of Aroostook want said tariff they should have some practical farmers present at the hearings on the Agricultural Schedule of the new tariff bill to testify as to the actual cost of raising potatoes in Aroostook as compared with Canada, as the basis of a protective taric would be the dicerence in the cost of production.

It would be a good idea for the New Brunswick Potato Growers' Associa-

The Specific for Diseases of the Horse

Cures : Cough, Heaves, Worms, etc. — It promotes health, strength and endurance in work, pleasure and race horses.

On Sale Everywhere. DR. ED. MORIN & CO., Limited, Quebec, Canada.

tion and the United Farmers of the potato growing counties to get authentic figures on the cost of production in New Brunswick to submit through the proper channels, as an effort against any attempt to discriminate against the Potato Growers of Canada.

The Federation is hot foot after a protective tariff, and is calling upon farmers and business men of every description to come to their assistance.

The Federation ships potatoes for its members on practically the same basis as the United Fruit Companies of Nova Scotia handle apples. They are planning to make four grades of potatoes and establish a trade mark. Every sack of potatoes will be stamped with the trade mark and an extensive advertising campaign carried on. This plan has worked splendidly in the sale of fruits of various kinds, all over the world. The United Fruit Companies find the uniform pack and grade brings repeat orders. The question of grading potatoes in New Brunswick was discussed at the annual meeting of the New Brunswick Potato Growers Association last winter, and grading will undoubtedly be practiced in the near future.

FARM EQUIPMENT

When there is a little spare money to spend for equipment that is very useful on the farm, some of the following articles might be considered. Four thermometers can be used on every farm to good advantage; one for the churn, one for the cellar, one for the living-rooms in the house and one to suspend near the most frequently used door-step. It is quite necessary to have a thermometer to use in churning in order to do the most satisfactory work. If there is any danger of vegetables in the cellar freezing during severe weather, the thermometer will act as an indicator when danger approaches and immediate protection can be furnished in the nature of lanterns or oil stoves to keep the temperature up to a safe level.

Frequently farm homes are overheated and there is no attempt made to regulate the temperatuer during the winter. A thermometer to aid in keeping the temperature around the comfortable and healthful sixty-eight degrees, will be very desirable for the health of the family. There is nothing more interesting than occasionally following the trail of the mercury on the porch. In spite of the fact that it is a commonplace subject, there is nothing much more important or interesting than the weather on a farm.

Farmers who never own an alarm clock manage to get up early from a force of habit, but when city helpers appear on the farm a little jingling on the gong is necessary to start business going at the right time. The alarm clotk can be used by the housewife to time the cooking and baking of various household necessities. When running an incubator or looking after sick live stock the alarm clock may be used to arouse the farmer at a certain hour during the night when attention to the work may be necessary to avoid serious losses.

The electric flash-lights possibly have more practical uses on a farm than in the city. The driver of an automobile will never wish to light any matches around the machine, either in the garage or at any stop on the road. If an examination of the car is necessary it is very dangerous to use a lighted match to help in determining the trouble. The flash-light is safe and furnishes an abundance of bright light just where it is most needed. When quick trips to the barn are necessary at night, the handy flash-light is less bulky and safer than the oil lantern. During sickness a light may be needed quickly in the home without electric lights and it will save time to have a flash-light by the bed. A substantial flash-light may save serious accidents on the farm while working around horses at night, and it is a great convenience and safeguard in the home whenever fire or thieves are suspected. It is just one of the handy farm helpers which are not absolutely necessary but yet very useful.

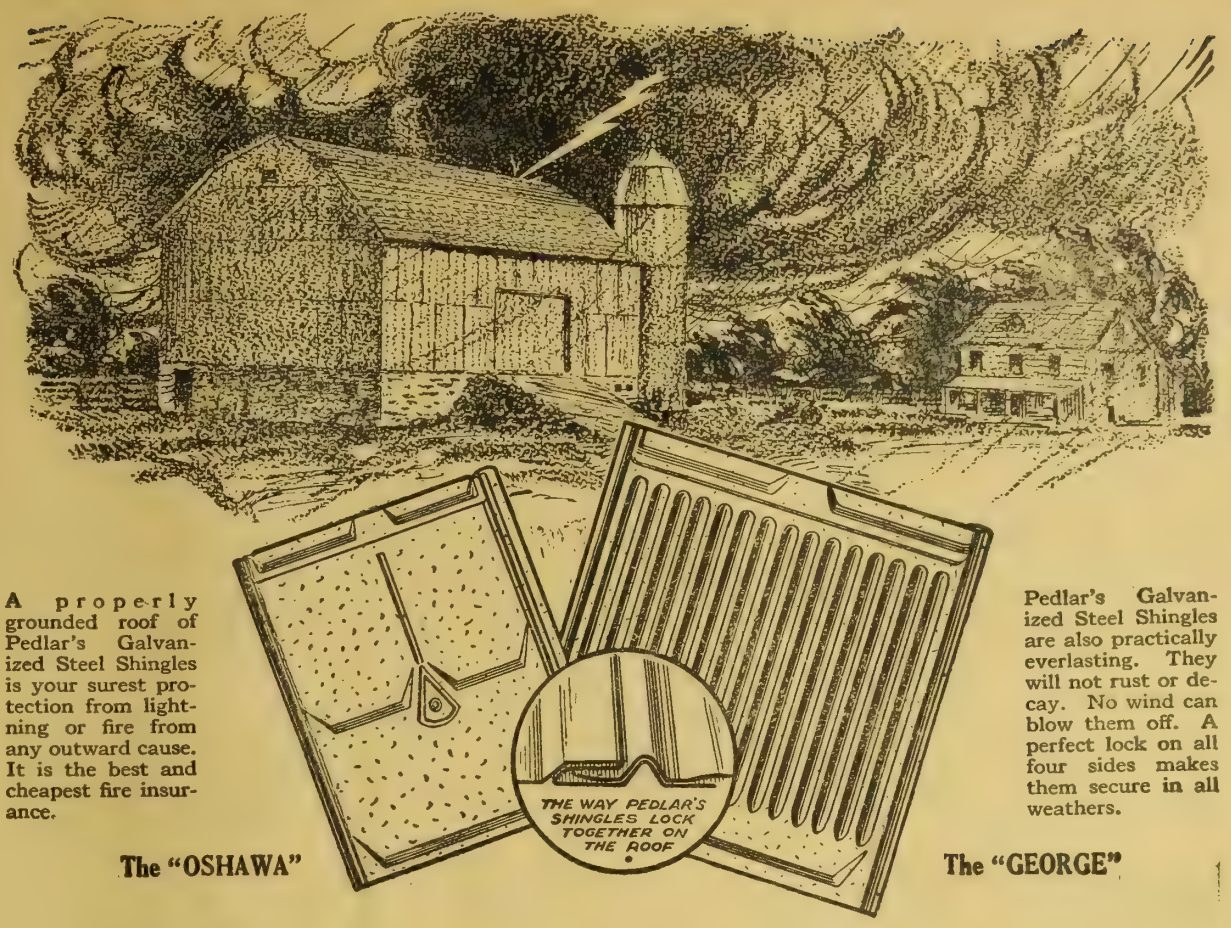
The keeping in repair of wire fences is necessary on the stock farm and so the wire stretcher is a handy tool, both in repairing and building new fences. Not many farmers own wire stretchers and they would be able to keep their fences in better condition if they had ready access to this handy tool. In many communities a substantial wire stretcher might be purchased in co-operation with several neighbors. It is not a tool that is needed frequently and yet it is very necessary in keeping the farm fences in repair and in building new fences. Tools of this kind last almost indefinitely and a farmer with a fair sized acreage can afford to own one as the yearly expense of owing such a tool can be spread over a large number of years.

Windows are often broken in the house, barn or poultry houses, and there is no glass cutter, putty, or glazier's points handy, the window may stay broken for a long time, even though there are plenty of pieces of glass on the farm that might be cut to fit the space formerly filled by the broken pane. The glass cutter and the putty knife are handy tools for the farmer and needed at the most unexpected time at any season of the year.

Both the step-ladder and the high ladder are necessary equipment that will be needed frequently. The step-ladder will be handy in picking fruit, pruning and repair work around the house and barn. The high ladder is valuable in fire protection. If a barn catches on fire it is very handy to have a quick means of getting upon the house to protect the roof from the sparks. In case of a small chimney fire spreading to the roof of the house, the farmer with a high ladder available might be able to save his home, even though the house might have burned if a trip to the neighbor's to borrow a ladder had been necessary.

The portable fire extinguishers are practical and may save much trouble due to fire on the farm. In the barn, the auto garage or in the home they can sometimes be used quickly to stop a fire that might cause serious damage to life and property. The presence of a fire extinguisher will give an added safety to many farm homes. There is a limit to the purse and the above mentioned articles are not absolutely necessary, but they are a practical investment and worth all they cost to the farmer.

It is the character of the men that make a cooperative asosciation and nothing else can or will. Our kickers are the men who bring to us everything that grows in the trees or fell on the ground and then kick because they have not as many No. 1's as the other fellow who is honest.—Elmer Lick, Oshawa, Ont., before Ontaria Fruit Growers.



A properly grounded roof of Pedlar's Galvanized Steel Shingles is your surest protection from lightning or fire from any outward cause. It is the best and cheapest fire insurance.

Pedlar's Galvanized Steel Shingles are also practically everlasting. They will not rust or decay. No wind can blow them off. A perfect lock on all four sides makes them secure in all weathers.

The "OSHAWA"

The "GEORGE"

Beware of Lightning

PROTECT your buildings permanently from the menace of lightning and all kinds of weather by roofing them with Pedlar's Galvanized Steel Shingles. Pedlar's "George" Shingles are 24 x 24 inches in size. 25 shingles cover 100 square feet. Designed especially for barns and other outbuildings Pedlar's "Oshawa" Shingles are used for shingling dwelling houses and other buildings where a more artistic appearance may be desired. They are 16 x 20 inches. 45 "Oshawa" shingles will cover 100 square feet.

We also manufacture Galvanized Corrugated Steel Siding; Galvanized or Painted Steel Siding, stone or plain pattern; Steel Roofing Tiles in many handsome designs; Metal Ceilings and Walls in a big variety of artistic patterns; Metal Garages; Eavestrough and Conductor Pipe; "Toncan Metal" Corrugated Culverts; and a big range of other Sheet Metal Products

No Motor is Better Than Its Spark Plugs

"Heavy Stone"
B 13, ½ in.
B 43, ⅞-18.
B53, ⅞-Long.
Price $1.25

Ball terminal when specified ; otherwise regular knurl nut

You may have the best motor in the world, but it cannot produce maximum power without efficient spark plugs.

On the same principle a spark plug is no better than its insulator, which must withstand the same hammering blows of gas explosions and the same rapid expansion as the steel cylinder in which it is placed. That is where 3450 insulators in

Champion

Dependable Spark Plugs
demonstrate their superiority

3450 separate experiments have produced in Champion insulators a material so much like steel in its ability to take the hardest kind of punishment that it is practically indestructible.

Do you wonder that four out of five gasoline motors and engines have Champion Plugs as standard equipment?

Sold wherever Motor Supplies are sold

Champion Spark Plug Co. of Canada Limited
Windsor, Ontario

Fawcett

New Rival

Is the last word in modern Furnace construction. It is the epitome of all a Warm Air Furnace should be.

Features:—Fire pot, sectional; radiator of heavy gauge steel; triangular grate; extra large feed door; deep ash pit; check damper; draft regulator; clean-out door, evaporating pan, joints cupped, packed with asbestos, cement and rope, absolutely gas tight. It burns hard and soft coal with equally satisfactory results. Fawcett New Rival has stood the rigid test of time and use. Insist on getting a Fawcett New Rival if you would heat your home comfortably, economically and satisfactorily.

Ask for circular on Warm Air Furnaces.

Ask your dealer to show you the Fawcett Line or write direct.

SACKVILLE · N · B · CANADA

FANNING-MILL SELECTION

(Experimental Farms Note)

The true function of the fanning-mill is to remove weed seeds, light grain and any coarse material that may be present. For this work it is indispensable; no seed should be sown which has not been thoroughly cleaned and graded. There are, however, certain limitations to this method of selection which are not always appreciated by the grain grower.

All impurities cannot be removed by the use of the fanning-mill as is sometimes claimed. It is true that a large part of them will be removed, but there are always kernels of wheat, oats and barley that cannot be separated. A short, plump, pin oat cannot be removed from wheat nor can a long, plump kernel of wheat be removed from oats. Barley and oats present a very difficult problem and the per cent of impurities remaining is much larger.

Fanning-mill selection maintains the yield of a pure variety, but does not increase it as many suppose. The constant increase in yield that some have obtained from year to year has been due to the fact that originally their seed was impure, and the larger seeds happening to be the most productive, were selected to the exclusion of the smaller and less prolific grains. Also, by the accidental mixture of a few large seeds of another sort, it can be easily understood how the type of variety may be altered if fanning-mill selection alone is practised. However, this possibility can be avoided, and should not deter any person from the use of the fanning-mill. Unless the grain is thoroughly selected by this method, seeds that are low in vitality will be sown, the result being either a defective germination or else weak plants that are handicapped throughout the season by a poor start. Grain from such plants is inferior in size and plumpness and reduces the quality and yield of the general crop.

To grow pure grain of strong vitality, the fanning-mill must be used in conjunction wtih the seed plot. In this way fanning-mill selection reaches its highest point of efficiency. All plants that are different in type can be removed before harvesting and this leaves to the fanning-mill only the work of rejection of the weed seeds and inferior grain. This combination ensures pure grain and maximum production.

CONGRATULATIONS TO PRINCE EWARD ISLAND'S NEW MINISTER FOR AGRICULTURE

Hon. W. M. Lea, of Victoria, P. E. I., has been appointed Minister of Agriculture and Provincial Secretary-Treasurer for his province. The Maritime Farmer takes this opportunity of congratulating Mr. Lea on his appointment, which is well merited.

Mr. Lea has been a consistent advertiser and frequent writer in the columns of the Maritime Farmer for many years. He is one of the best and most practical farmers of the Island Province and as chief of the Agricultural departmet should prove an able administrator. His Holsteins have been leading prize winners at all our Maritime shows. He represented his constituency during the last term in the Island Parliament on the opposition benches. His precept and example should inspire the utmost confidence in his department. We know the many breeders and exhibitors who associated with him at the fairs will join with his many other friends in wishing him every success in his offical capacity as Minister for Agriculture of the Island Province.

A PLUMPER FOR HOME MIXED FERTILIZERS

Editor the Maritime Farmer:

I was very much interested in an article which appeared in the September 4th issue of the Maine Farmer, over the signature of Geo. V. Brown, Secretary of the Aroostook Federation of Farmers.

I am forwarding an extract to you for publication as I feel the subject matter will be much interest to many of the readers of The Maritime Farmer.

"Now that digging has begun, the "falsity of the claims made by the "fertilizer agents last spring are be-"coming daily more apparent. Not a "poor piece of potatoes out of over "2000 acres planted on home-mixed "goods that cost $35.00 or more a ton, "less than ready mixed commercial "fertilizers. Hundreds of acres ruined "by the use of commercial ready-mix-"ed fertilizers.

"Fertilizer agents stated last spring "that the chemicals sold by the Fed-"eration would cake and could not be "used in the planters, that they would "rot the seed, and that they were in-"ferior goods and wouldn't raise a "crop, etc., all of which was absolutely "false. No fertilizer ever worked any "better in the planters, no better stand "of plants could be found than where "these goods were used. All summer, "where used side by side with the best "of the ready-mixed goods, the home-"mixed showed their superiority, and "now at digging they are in every case "equal, if not better, than fertilizers "costing $35.00 per ton more.

"Are you going to believe those "agents when they come around this "fall with honey words and specious "promises of what their goods will do, "and what they know about fertilizers?

"Mr. Brown goes on to say that the "Federation will be in position to sup-"ply chemicals this fall at a price that "will sound good to the potato grower "—chemicals that will be better goods "than any ready-mixed fertilizer com-"pany will sell and that will not con-"tain anything injurious and no use-"less material such as hair, wool "waste, horn and hoof meal and other "sources of nitrogen used in a great "deal of commercial fertilizers. Don't "patronize anyone who has fooled you "in the past and who is knocking "farmers' organizations."

The results procured by the farmers of Maine through the use of home-mixed fertilizers is identical to the results procured by New Brunswick farmers which they have for a number of years been purchasing co-operatively through their agricultural societies and the New Brunswick Agricultural Societies United.

The canvasses used against home-mixed fertilizers in Maine bear the same ear marks of the canvasses used in New Brunswick by men who have an axe to grind. Our farmers are, however, staying with the game. Once a user of home-mixed fertilizer, always a user is the history in this province. They are getting satisfactory results at a minimum cost.

In regard to the damage done by ready-mixed fertilizers in Maine during the past season, not all brands of commercial fertilizers gave such disastrous results. While motoring in Aroostook County last July I met and talked with farmers who were loud in their complaints against certain brands of fertilizer they had used. In one district I learned that indignation meetings had been held to institute damage actions against the manufacturers who had placed injurious goods on the market.

I did not hear of any damage from ready-mixed fertilizers on the Canadian side of the line.

FERTILIZER USER,
Carleton County, N. B.

NEW WORLD'S RECORD

Little Gift of Spring Valley, an American bred Holstein cow owned by W. S. Moscrip, of Lake Elmo, Minn., has just broken the world's record for one day's milk production, producing 155.44 lbs. milk in one day, which takes the record away from the Canadian champion, May Echo Sylvia. The latter still holds the championship for 7, 30, 60, 90 and 100 days. Little Gift is now on semi-official test, and is expected to add new honors to her already illustrious name. It will be remembered that she made, a few years ago, a two-year-old record of 18,205 lbs. milk, containing 742 lbs. butter, and dropped twin calves sixteen days after her year was up.

Rolla Mercena DeKol, the world's champion 51.93 lb. butter cow, sold for $26,000 at Moyer's sale of Holsteins, held at Philadelphia, Pa., last week. She was consigned by J. B. Hanmer, of Norwich, Ont., and purchased by Cold Streams Farm, Lexington, Ky. A daughter of this cow, Glenotter Rolla DeKol, brought $7,100.

TRAPPERS AND HUNTERS
For highest prices ship your RAW FURS direct to

We will send you a FREE SAMPLE of Hallam's Paste Animal Bait

This is an entirely new and much improved form of Animal bait—it is made in a paste form and put up in tubes (like tooth paste).

While possessing all the excellent qualities of the liquid bait it lasts longer and is unexcelled for attracting all flesh eating animals, such as Mink, Fox, Wolf, Lynx, Skunk, etc.

It is easy to carry, economical and handy to use, (simply squeeze out enough for your set each time)—not affected by snow or rain.

You can have a FREE sample for the asking (enough for 2 or 3 sets).

We will also send you Hallam's Trappers and Sportsmens Supply Catalogue, 48 pages, (in English and French) showing traps of all kinds, guns, rifles, ammunition, fish nets, shoepacks etc., at very moderate prices.

Hallam's Raw Fur News contains latest information on Raw Fur prices and market conditions, sent free on request.

Celery.—1st, Miss Amelia J. Kirk;

In the dark winter mornings or cold raw days of Fall and Spring, it is no joke getting up in the morning. That job of cleaning the stable has to be tackled and it is mighty hard work.

Cleaning the stable with a wheelbarrow is a tiresome, disagreeable, task. It is just about the hardest job on the farm, particularly when the yard is sloppy and the planks slippery.

There is no need to do all that hard labor if you have a BT Manure Carrier. You take out three barrow loads at a time that means fewer trips. You are absolutely independent of the conditions in the yard, because the track runs overhead.

Fill the big open-mouthed bucket, windlass it up and run it out sixty or a hundred feet from the barn. Then pull the trip latch and dump the manure in a neat compact pile. In this way, rain and frost will not spoil its fertilizing value.

You will use your BT Carrier every day. It will save you time, labor, manure and hours of hard work. By saving an hour a day, you will have more time to work in the fields. On Sunday you can be done in lots of time for Church.

The coupon will bring our catalogue with full particulars. Cut it out and send it to-day.

(To be continued)

PRESERVE NURSERY STOCK DELAYED IN TRANSIT BY "HEELING IN"

It is sometimes difficult for communities or individuals located at some distance from the postoffice, along a rural mail route, to get trees and shrubs from nurseries in a fresh condition. Owing to the irregular mail service, often times nursery stock is pretty well dried out when received by the purchaser. Trees and shrubs must be fresh if they are to survive after planting. The following suggestion from Prof. W. J. Morrill, of the Colorado Agricultural College, may prove helpful:

"Have someone receive the stock immediately upon its arrival at the postoffice or express office at the other end of the route. Have them heel the trees in a moist, shallow, trench, covering the roots with moist earth and leaving the tops out but shaded from sun or protected from drying winds, and so hold until someone is coming to your place or until you can go in to get them. The trees will thus be protected from drying out and will be in good condition, with such treatment, for a week or so. In carrying them home, keep the roots moist and covered, away from the sun and dry air."

Saves Shortening

One of the first things you notice, after "Beaver" Flour comes to your house, is that you are using *less shortening* than you used with western spring wheat flours.

You also notice that the Pie Crusts, Cookies and Doughnuts are lighter and flakier—that the Bread Rolls and Biscuits have a delicate flavour, a delightful, nutlike, homey flavour that is doubly welcome after the tough, almost tasteless bread you used to make with western spring wheat flours.

BEAVER FLOUR

Milled of Blended Wheat

is really two flours in one, for two kinds of wheat are used in blending. "Beaver" Flour contains the choicest Ontario winter wheat, strengthened with western spring wheat.

This gives you the finest pastry flour that can be milled—with the right strength to make a good size loaf of bread or a big pan of snowy Rolls.

More than that, everything made of "Beaver" Flour has a deliciously appetizing, nutlike flavour that is entirely lacking in the strong, western spring wheat flours.

Try it yourself—see how you save shortening—see how you come to depend on the even strength and quality of this famous flour—see how everything tastes so much better. Your dealer should have "Beaver" Flour—or will get it for you.

DEALERS—write for prices on Feed, Coarse Grains and Cereals. 199

THE T. H. TAYLOR CO. LIMITED, - - CHATHAM, Ont.

FEEDS IN CAR LOTS

Are you interested in feeds in car lots? The Maritime Farmer is in a position to supply agricultural societies with feeds of proven worth, at prices which will save many dollars for those who are willing to co-operate in buying. We are offering 36 per cent protein cotton seed meal at prices which are most attractive. The terms are sight draft attached to bill of lading, payable on presentation. We offer car lots at about fourteen dollars per ton below some of the wholesale quotations, subject to acceptance by the mill. We will guarantee the goods to be equal to any you have ever used and superior to many brands of cotton seed meal on the market. Write us for quotations. We would ask you to remember that the tendency of the feed market is upward. Feeds are scarce and in great demand. There may be an advance in freight rates, too, which will increase prices. The early order is a winner.

A VERY VALUABLE BOOK

The Veterinarian, by Charles J. Korinck, V. S., is a work on the afflictions of horses, cattle, sheep, swine, poultry, etc., which every farmer should have in his home. The story of how treatment can best be administered is told in simple every-day English that any person can understand. The methods suggested by Prof. Korinek are simple and easily followed. The book will cost you seventy-five cents, postage paid. It may be the means of saving you as many dollars in the near future. How many men are there who meet trouble by writing to the Maritime Farmer or some other paper for information which will be found in the Veterinarian? It is strongly bound in cloth, has serviceable illustrations and is well indexed. Seventy-five cents will bring it to you.

MAKE YOUR OWN CALF MEAL

The Beaver Mfg. Co., Ltd., Galt, Ont., manufacturers of Herbagum, advise farmers to make their own calf meal as follows: 100 lbs. oil cake meal, 100 lbs. feed flour, 200 lbs. wheat middlings or fine shorts, 1 lb. fine salt and 4 lbs. Herbageum. Mix thoroughly and stir about two cupfuls in a gallon of scalding water and feed warm. If oil cake meal is not obtainable at a fair price use ground oats. By acting on this advice the best results at least cost will be ensured.

Herbageum is 25c per lb., so the cost of the 405 lbs. of calf meal is easily figured.—Advt.

W. A. ERB, SUSSEX, N. B.

APPLE CIDER

Prohibition has created a great demand for non-intoxicating beverages and nowhere is this demand more in evidence than in the case of our fruit juices. This fact should not be overlooked by those who have apples going to waste. There is a good chance to turn such fruit into a profitable source of revenue by making it up into cider.

It is predicted that with the increased demand, apple cider, this fall and winter, will sell for anywhere from thirty cents to one dollar per gallon. Much cull fruit which might not otherwise be profitably disposed of may be utilized in this way.

Care in washing the fruit used and in discarding the decay and wormy apples will help in building up a trade.

Hard cider is, of course, tabooed, and as sweet cider is a more or less perishable product, suggestions in regard to keeping it sweet may not be amiss.. Either of the following methods described in the American Fruit Grower is effective:

(1) "Cider can be kept indefinitely with flavor and appearance unchanged exactly the point desired and allowable —and you don't have to use poisonous preservatives either. Just filter it and then pasteurize it in the final container (bottle or jug) sealed tight at about 150 degrees F. and hold it at that temperature for half an hour and you can't tell it from fresh new juice."

(2) "Perhaps the most simple method known is to screen the cider through a cloth to remove the larger particles of solids, put in a copper kettle, evaporating pan, or steam evaporator and heat until it will just come to a boiling heat. Meantime keep skimming off the scum as fast as it rises. The moment the juice comes to a boil, shut off the heat and pour into sterilized gallon jugs or other containers in which it can be corked up tight. The corks should be pressed a little below the level of the top and covered over with esaling wax. Then store on the floor of a cool cellar and the juice will keep for many months."—R. A. McGinty, Colorado Agricultural College, Fort Collins, Colorado.

Auto Tires $17.50

Fine non-skid tire for small cars, size 30 x 3½, fully guaranteed for 3500 miles

The Maritime Farmer begs to announce a substantial reduction in the price of non-skid tires for small cars, Fords, Chevrolets, Maxwells, etc. They are FIRSTS, fully guaranteed and we will sell them to you, provided you are a paid-up subscriber to the Maritime Farmer for $17.50 f. o. b. Sussex. Plain tires for $16.25, fully guaranteed for above mileage. Tubes for same size tire $2.90. These goods are all A1 stock and are made by a well known tire house. Of course these prices are for spot cash with order. The Maritime Farmer was able to take advantage of the recent break in the market and its large buying capacity to get you the benefit of this substantial cut in price. IT'S THE BEST BUY IN CANADA Today. Write the Auto Department, Maritime Farmer, Sussex, N. B.

"YOU SEE IT'S A MARITIME FENCE"

Maritime fences will stand the severest tests, because they are built throughout of extra heavy hard drawn No. 9 steel wire. The superior stretching power of No. 9 wire keeps the strands from snapping under heavy strains or hard frosts. Each fence is thoroughly galvanised and will sturdily resist the rust and rot of weather.

STANDS THE TEST OF MAN, BEAST, WEATHER and TIME

The strands and stays are firmly gripped at every join by our special time tried and tested never-slip lock. Even after years of hard service, Maritime wire fence retains its sagless shape and sightly appearance. All Maritime Fences are carefully inspected and rigidly tested before leaving the factory. When you buy it you know you have got something that is bull strong and hog tight, something that will withstand greater strain than it is ever likely to receive.

Before you buy fencing it will pay you to first learn what the Maritime has to offer in the way of real fence service.

For sale by agents and dealers in nearly every section.
If you don't know the local dealer, write to us direct.

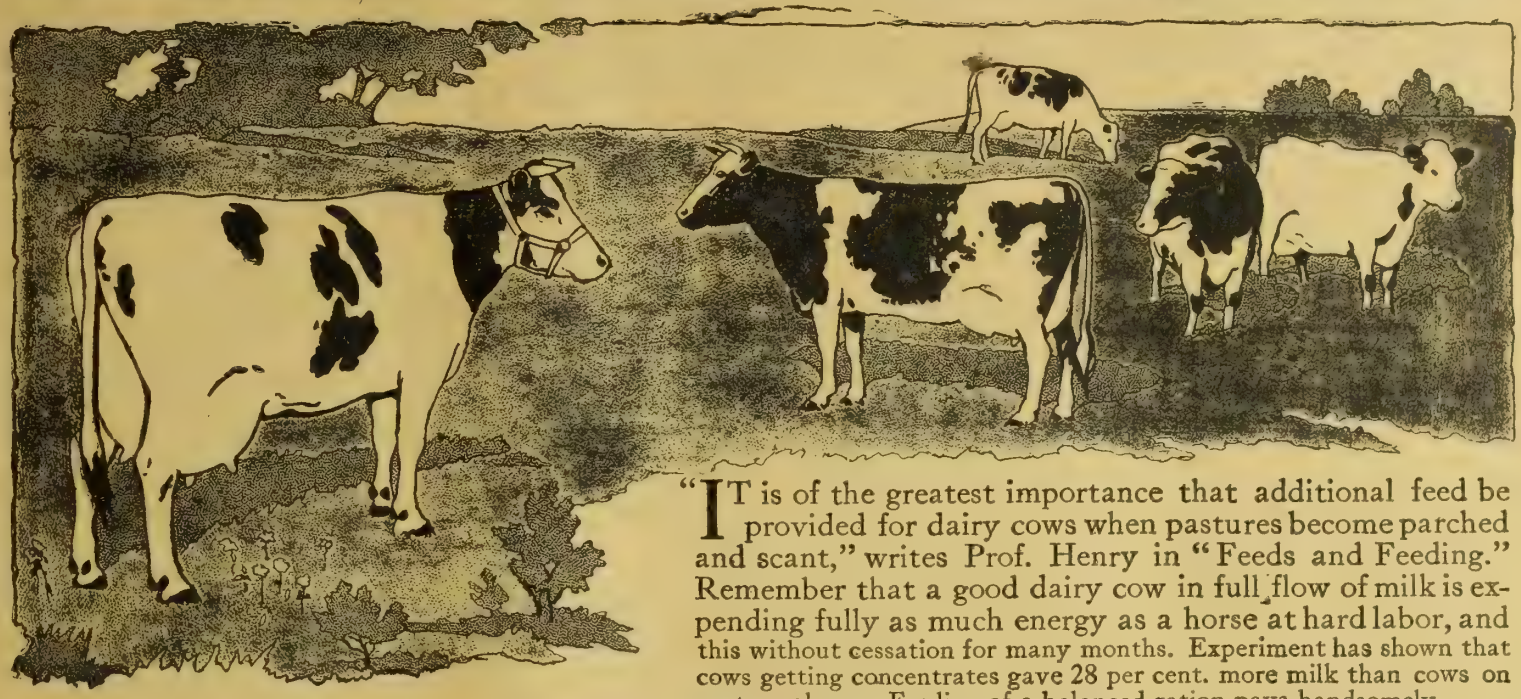
Heavy Flow of Milk Over Long Periods



"IT is of the greatest importance that additional feed be provided for dairy cows when pastures become parched and scant," writes Prof. Henry in "Feeds and Feeding." Remember that a good dairy cow in full flow of milk is expending fully as much energy as a horse at hard labor, and this without cessation for many months. Experiment has shown that cows getting concentrates gave 28 per cent. more milk than cows on pasture alone. Feeding of a balanced ration pays handsomely.

Monarch Dairy Feed

is composed of oil cake meal, cottonseed meal along with such bulky feeds as bran, corn feed and barley feed. The oil cake meal has a rich store of crude protein and slightly laxative oil which accounts for the sleek coats of cows fed with Monarch Dairy Feed. Cottonseed meal is also a high protein feed, but is greatly improved when mixed in proper proportion with other feeds. In most cases cottonseed meal is the cheapest source of protein. Cottonseed meal is opposite in its effect to oil cake meal in that it is rather constipating and makes a hard butter fat. A combination of the two therefore gives ideal results. In feeding finely ground protein feeds, such as these, it is necessary to add bulk and to lighten them up for better digestion. For this purpose we use bran, corn feed and barley feed. These ingredients also make the feed more palatable.

Monarch Dairy Feed while being very rich, may be safely fed alone. Guaranteed analysis, protein 20%, fat 4%.

Monarch Dairy Feed supplies *all* the requirements of the cow, for concentrates, to give the highest production of milk.

Monarch Hog Feed

A special feed that meets all the requirements of the brood sow and the growing pig; consists principally of corn meal feed, shorts and digester tankage. Guaranteed analysis, Protein 15%, Fat 4%.

Sampson Feed

Meets the demand for a general purpose feed for both cattle and hogs. It is sold at somewhat lower price than either Monarch Dairy Feed or Monarch Hog Feed. Guaranteed analysis, Protein 10%, Fat 4%.

Give Monarch Dairy Feed a trial. Order a ton from your dealer; if he does not handle Monarch Feeds, write us direct giving dealer's name and we will tell you how to get Monarch.

Canada Food Board License, 6, 7 & 8. 50

LOCATION OF FARM BUILDINGS

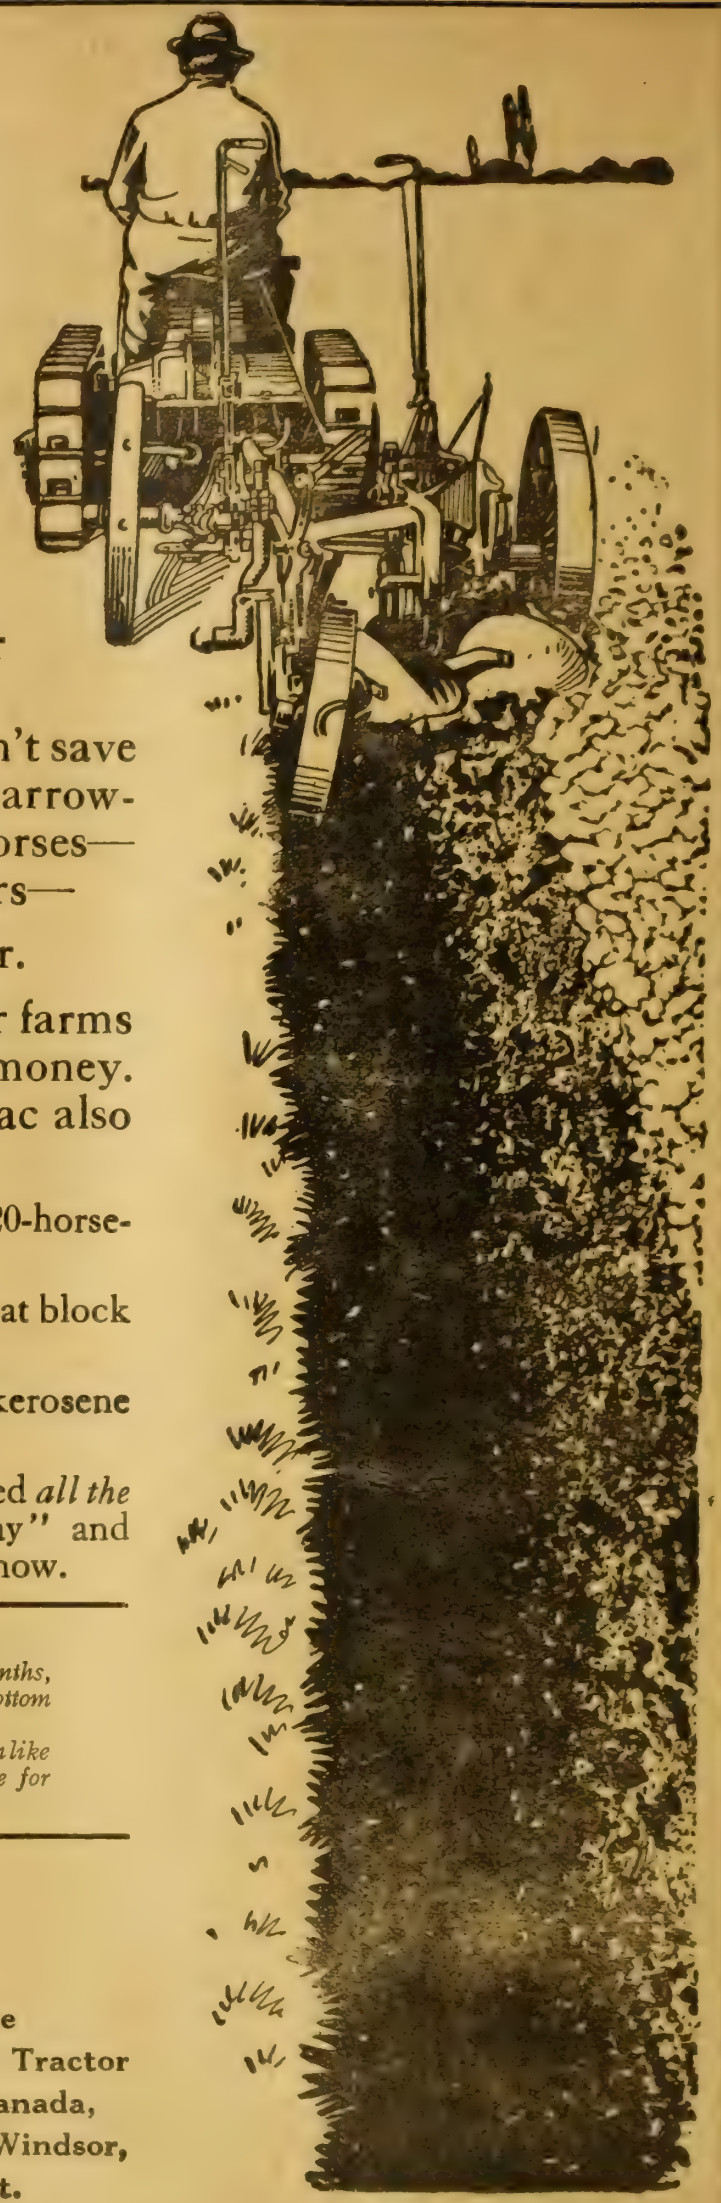
Location of farm buildings is of the greatest importance in saving time and labor. A different problem is present on different farms, so that it is impossible to lay down hard and fast rules for locating farm buildings. Local conditions, such as natural drainage or slope, will affect the location to a great extent. F. A. Meckel, of the University of Missouri College of Agriculture, gives the following suggestions for the location and arrangements for farm buildings:

1. The farmstead should be conveniently located with respect to the fields.
2. The farmstead should be near an improved road.
3. The barnyards and lots should be well drained, either by natural drainage or tiles.
4. Have troughs emptying into drains or cisterns will eliminate much mud in barnyards.
5. An exposed hill is undesirable, but a south slope is to be desired.
6. A timber windbreak will prove valuable on the north and west of the farmstead.
7. The buildings should be grouped around a central courtyard.
8. The granary should be convenient to the barn and hog-houses.
9. A water supply must be available. Running water in house, barns and yard is a great convenience.
10. Barnyards should not face the house or road.
11. The barn and yards should be 150 to 200 feet from the house, and not in the direction of the prevailing winds.
12. The house should be set well back from the road to avoid the dust.
13. The house should command a view of the barn door, the front entrance from the door, and the central courtyard.

Cletrac

TANK-TYPE TRACTOR

Puts More Land Under Crop



IT is a proven fact that the Cletrac Tank-Type Tractor saves money on the farm.

But—if the Cletrac Tank-Type Tractor didn't save a dollar of the cost of plowing, discing and harrowing—even if it cost more than farming with horses—it would still be a boon to progressive farmers—

—a sound investment and a big profit-maker.

Farmers who own Cletrac Tractors have their farms in good shape—more of their land is earning money. And because it fits the land better, the Cletrac also increases the yield per acre.

12-horsepower on the draw-bar. On the belt pulley 20-horsepower. Works 365 days in the year.

Plows 3½ miles an hour. Climbs in and out of places that block other tractors. Low-set—it can work under trees.

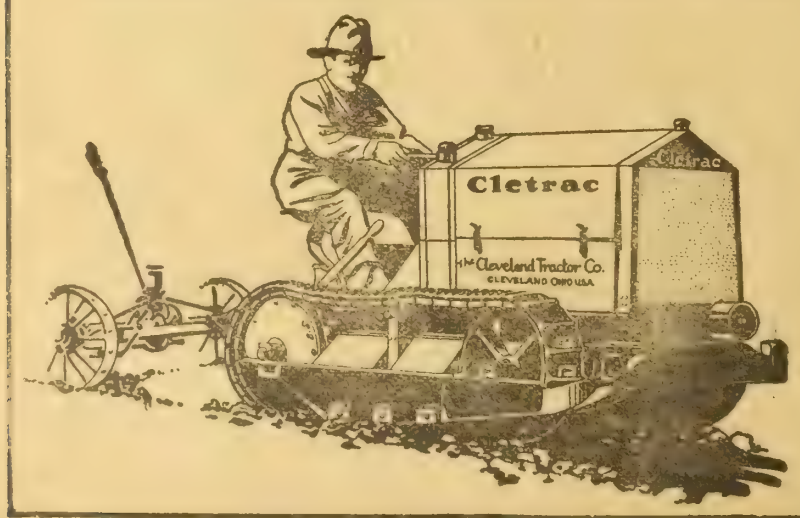
The Cletrac is a *kerosene* (coal oil) tractor—uses no more kerosene than most tractors use of gas.

Don't make a decision on the tractor till you have studied *all the facts*. Two most interesting books "Our Owners Say" and "Selecting your Tractor", free for the asking. Write now.

J. M. Boyd of Belleville writes us:

I have been operating my Cletrac Tank-Type Tractor for over three months, doing all my Fall plowing, discing, cultivating, etc., using three 10" bottom plows, with excellent results, on clay land which is more or less stony.

I have had it operating a 13" Gilson ensilage cutter on a 36-foot silo with like results, and was surprised at the simplicity in lining up this little machine for belt work—I used no bracing.



The Cleveland Tractor Co. of Canada, Limited, Windsor, Ont.

Wanted—

a man to represent in his home-territory and in his spare time, the world's largest cream separator manufacturer

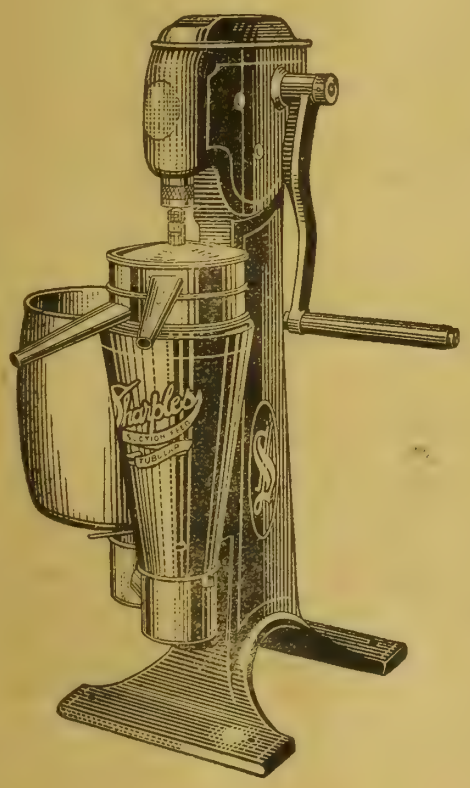
The Sharples Separator Company, the world's largest manufacturers of Cream Separators, Emulsifiers, Clarifiers, Whey Separators and Factory Separators, is about to enlarge its selling force.

The success of Sharples representatives in the territories that are now covered. insures an excellent opportunity in the new field for the right man.

The man we want is a capable successful farmer—who knows his neighbors and whose judgment is respected by them. If he is a Sharples owner so much the better.

He may devote to his work for us as much or as little of his time as he may elect. His territory will be his own.

He will find that the Sharples Suction-feed Separator has convincing and demonstrable selling points (skims clean at any speed, knee-low supply tank, no discs to wash, less than $2 a year guaranteed for oil repairs, etc.), that are not even **claimed** for any other separator.



He will find a host of Sharples users who will be glad to offer proof of Sharples' superiority in actual usage.

He will find that farmers already know of Sharples Separators through our extensive national advertising.

We want such a man in your territory. You can make this opportunity mean much to you if you will. Write today for exclusive contract and prices.

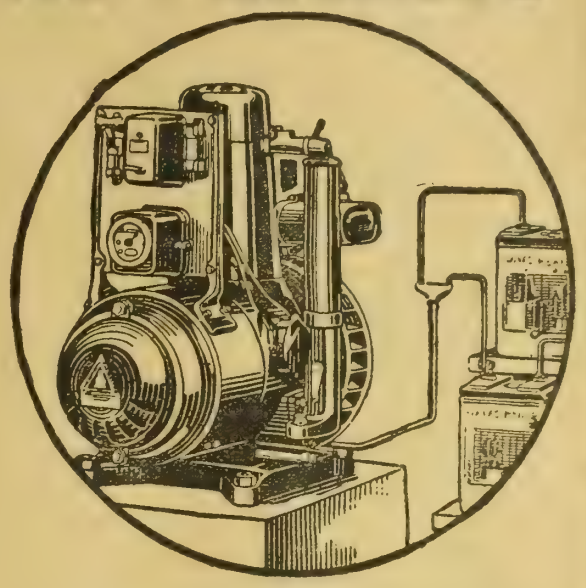
A Business Proposition for Farmers

WE want you to size up Delco-Light as you would a new farm hand before you hired him.

Will Delco-Light do a good day's work on the farm every day? Will it cost much to keep? Will it earn money for you? Will you get along pleasantly with it.

Over 75,000 Delco-Light users have answered these questions for themselves and for you.

Delco-Light gives them all the electric light and power they need.

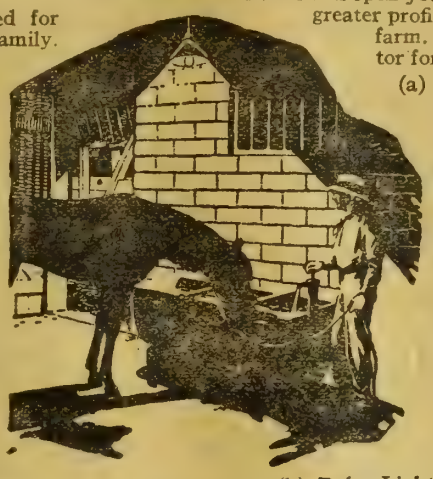


As a result—

They do chores before daylight or after dark, because house and barns are well lighted.

They have stopped working small machines by hand—milking machine, churn, separator, grindstone, washing machine, fanning mill, water-pump. They have running water wherever it is needed. They no longer hamper themselves with a lamp or lantern while working. There are no lamps to clean and fill. The ironing is done by electricity.

All this means time saved for every member of the farm family. It means more time spent at money-making work. On some farms it means doing away with hired help.



And the money now spent for coal oil will operate Delco-Light. Four times as much light from a gallon of coal oil is the record of Delco-Light over oil lamps. A few cents a day for all the electric light and power you can use.

Where there is a boy on the farm, he looks after Delco-Light. A few minutes each week is all the attention it needs. Note these exclusive features of Delco-Light construction. They insure care-free, long-lasting service for you.

It is direct-connected. There are no belts to slip, break or be replaced.

It is self-cranking. Pressing down on a lever starts the engine and it stops automatically when the batteries are charged.

It is air-cooled. There is no water to carry, to freeze, or to boil away.

There is only one place to put oil. There are no grease cups.

A simple mixing valve regulates the fuel supply. There is no complicated carburetor.

Ball and roller bearings cut down friction and increase efficiency.

Thick-plate batteries are long lasting.

You can see that on every point Delco-Light is a good business proposition—that it pays for itself. It does a lot of work for you. It saves you time. It gives you time for money-making work. It costs little to operate. It is easy to look after.

BESIDE ALL THIS, Delco-Light gives you the wonderful comfort and pleasure of electric light in the home. Floods of clear, bright light at the pressing of a button. No matches; no danger. Lots of light. Pleasant evenings; happy mother and children. You can't know the untold benefits of electricity until you try it.

Delco-Light users know all these things. They have written us letters telling us. We quote from some of these letters. We have printed some of them in a little folder. Illustrated with photographs. We want you to get this book and read it. It will open your eyes to the possibilities for greater profit and greater comfort on the farm. Write your nearest distributor for a free copy.

(a) DELCO-LIGHT has made it possible for us to do without one man, whose wages and keep amounted to $50.00—he would cost us more now.

By operating the above mentioned appliances Mrs. Peck has been so relieved from her ordinary household duties that she is able to spend a great deal of her time helping to care for the milk, and we are now able to do all of our own work, which has solved the hired help problem for us, and securing help nowadays is the farmers' greatest problem.

(b) Delco-Light saves us every day about one hour doing the chores around the farm—this would mean for my son and I about 730 hours a year at 30c. per hour, which is, figuring very low, about $219.00 saved.

(c) The time and labor saved every week over the old way is as follows:

Cream Separator.....	6	hours
Washing Machine.....	5	"
Flat-iron.....	2	"
Pumping water.....	6	"
Vacuum Cleaner.....	4	"
Power Stand on Fan Mill and various things...	2	"
Total.....	25	" per week

(d) I save about 2 hours a week on the washing, and 7 hours a week on separating. It saves one man about 4 hours to clip my team. On churning it saves my wife 3 hours a week. It saves about 30 minutes on grinding our sausage per hundred pounds.

(e) We figure that it has saved us in way of labor for pumping and milking not less than $1,200.00 during the two years. The plant requires very little attention and only about $2.00 per month for fuel. We could almost afford to buy a new one each year and still be ahead on labor and satisfaction, aside from the advantages of having the lights, of which we have 50 in the house and barns.

(f) I light my residence, a house of fourteen rooms and one of five, my garage, two barns and a workshop. I operate an automatic water pump, maintaining a pressure of 40 pounds for the entire water supply of the place, including hose for watering the garden. We have a ½-horse power Delco-Light Power Stand, which is used for churning and working the butter, turning the grindstone and running the washing machine. I expect to attach it later to the cream separator.

(g) This plant is paying for itself in several different ways. The fuel saving alone amounts to about $460.00 per year, as follows:

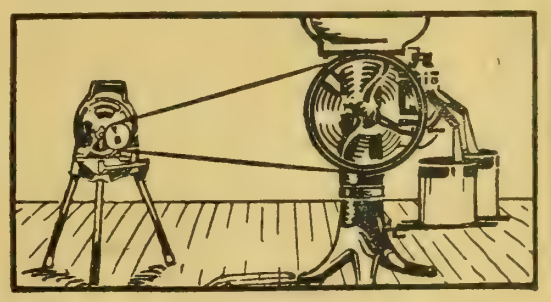
Where we formerly used 55 gallons of gasoline per week, at 25c. per gallon ($13.75) to operate the milking machine and pump alone, we now use 35 gallons of kerosene per week at 14c. per gallon ($4.90), which is a net saving of $8.85 per week, or $460.20 per year.

Also, in addition to this, we are lighting four houses, horse barn and cow barn and doing the washing and ironing.

Another instance of saving is that we save the time of one man (4 hours a day) handling lanterns alone in our cow barn. We figure this a saving of 30c. per hour, making $1.20 per day, $36.00 per month, or $432.00 per year.

(h) "I consider my purchase of a Delco-Light plant one of the best improvements I have made on my farm." DUNCAN MARSHALL,
Minister of Agriculture, Alberta, Canada.

(i) The plant has not given us a bit of trouble,



there have been no repairs to date and the operating cost has been less than $2.00 per month.

(j) Any child can run it and it beats any of your coal-oil lamps for light and safety. Before acquiring a Delco-Light I could not rest good at night for fear of children lighting a match and thereby possibly setting fire to something. Now I sleep like a log because all that is necessary for the children to do is to press the button and the light is there, and a most excellent light at that. It is much cheaper than Coal-oil and no danger of upsetting a lamp.

DELCO-LIGHT

The Complete Electric Light and Power Plant for Farms

100% Reserve Strength

Power at Lowest Cost Year After Year

WILL this light tractor, that develops no less than 2,000 lbs. draw-bar pull with only 3,700 lbs. weight, stand the strains of heavy work? Not only will it do so but it has no less than 100% of additional strength to spare for emergencies!

Why pay the extra cost of a heavy cumbersome tractor when this 100% "factor of safety" assures you not only of better service the first year, but of absolutely dependable service year in and year out? The

Happy Farmer TRACTOR

gives you its 2,000 lb. draw-bar pull, not by great weight of metal and correspondingly heavy engine power, but by the results of proper design.

Eighty-eight per cent of the weight is carried by the two big driving wheels. They grip the ground for heavy work, yet the whole tractor is so light that the wheels make less impression than horses' hoofs.

By this careful distribution of weight less metal is needed and strains are reduced to the minimum. There are but two-thirds the number of parts used in ordinary tractors.

Owing to less weight, less power is needed to propel the tractor. The power needed to move ordinary tractors along is, in the Happy Farmer Tractor, applied to the draw-bar where it really counts. As an economical source of power, the Happy Farmer knows no equal. It means more horse-power for your money.

If you want cheap power plus lifelong satisfaction, get a Happy Farmer Tractor.

Write us for free literature giving full details. Send a postal to-day.

Turns In Its Tracks

Line Drive Attachment

YOU can easily attach this simple line-drive to your Happy Farmer Tractor. With it one man can ride on binder and control both tractor and binder. The line-drive attachment soon pays for itself by saving the wages of extra man on binder, manure spreader, hay loader or mower. It works simply, easily and effectively. Write for particulars.

KEEP
Holstein-Friesian Cows

1. The Holstein-Friesian is a large vigorous cow, full of energy and abounding in vitality.
2. Her physical organization and digestive capacity are such that she is able to turn to the best advantage the roughage of the farm, converting the same into merchantable products.
3. She yields large quantities of most excellent milk, fit for all uses and especially suited for shipping purposes.
4. Heredity is so firmly established through her long lineage that she is able to perpetuate herself for the production of strong, healthy calves.
5. When for any reason her usefulness in the dairy is at an end, she fattens readily and makes excellent beef.

If you can't buy a herd, buy a heifer

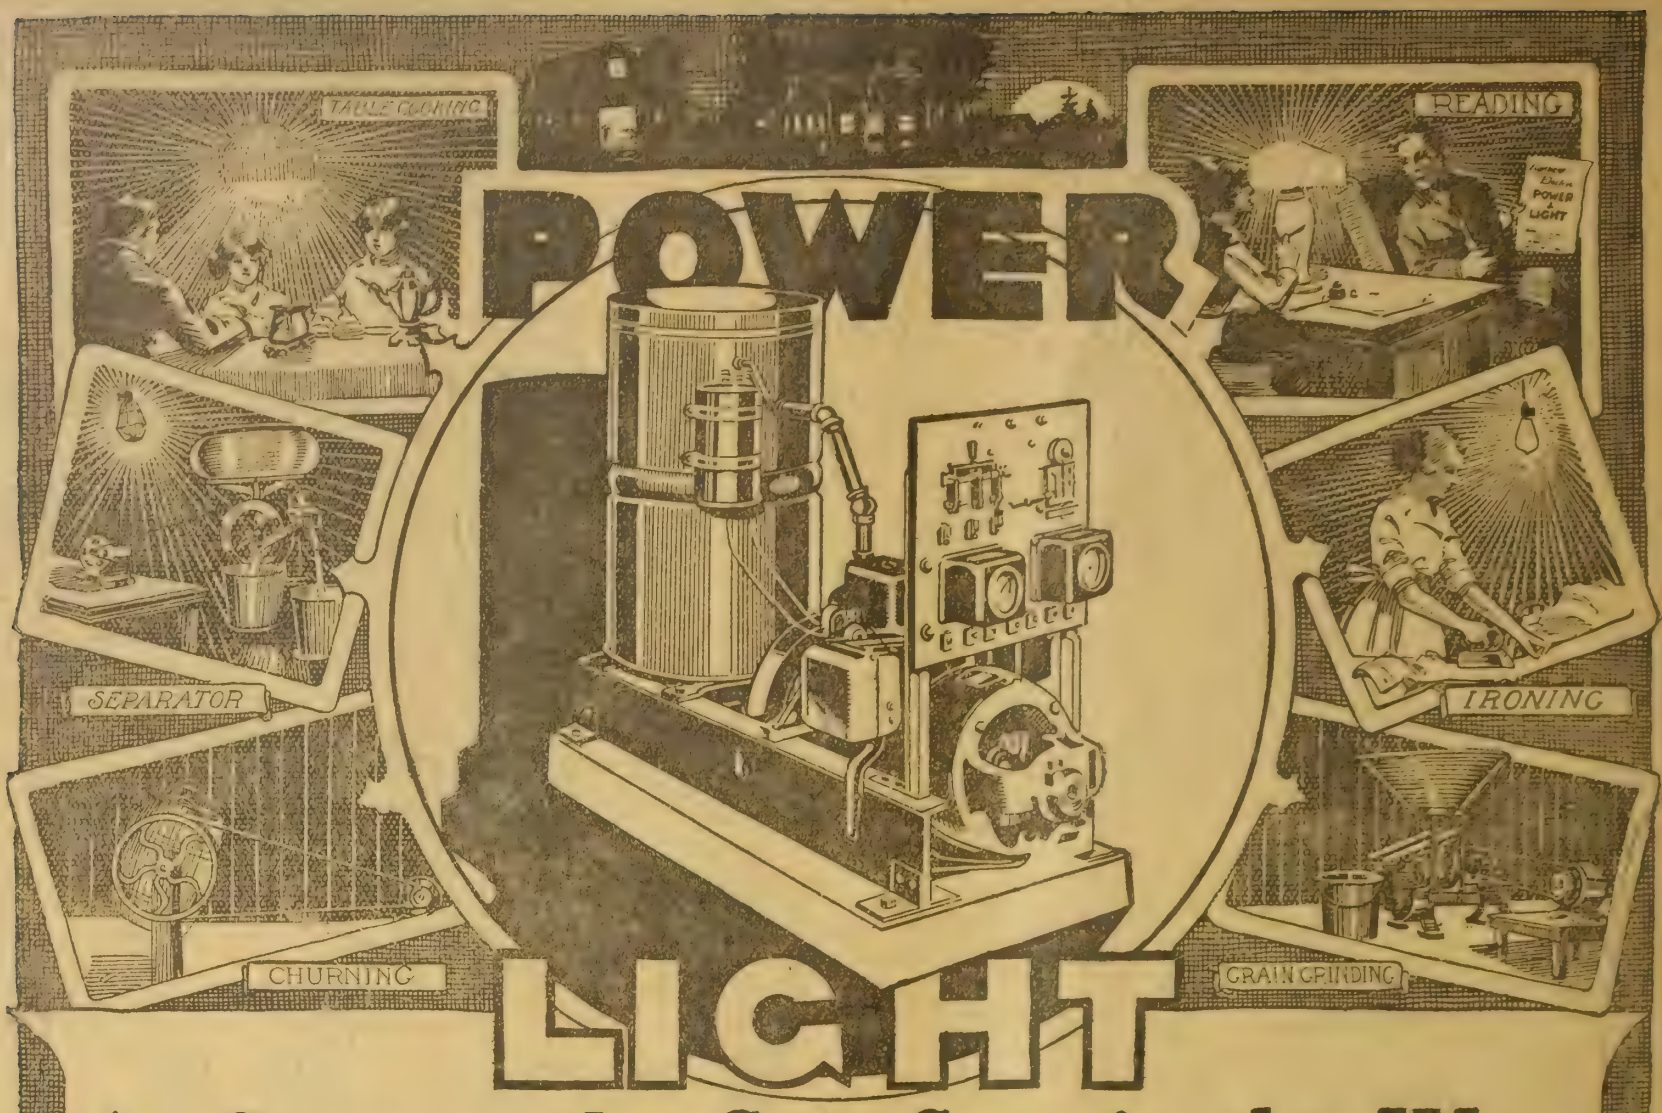
Advertise in the Farmer. Advertise in the Farmer.



As Sure as the Sun Sets in the West so Sure will you Need Electricity on the Farm

APART from altering international boundary lines, the war has shown farmers how to concentrate; how to devote their time and energy to big and important things. But what about the little jobs? Somebody has to do them; to turn the cream separator, churn, grindstone, grain grinder, saw wood, pump water, etc. These are the chores that the

Northern Electric POWER and LIGHT

will do for you. Jobs that take muscle and time from the big end of farm work. Then, too, there is the domestic side of farming. Electricity in the home means wholesome freedom from many daily drudgeries. It will run the washing machine, iron, vacuum cleaner, sewing machine, operate the toaster and many other electric household utensils. It will flood your house and outbuildings with a safe, bright, clean and economical light. No oil lamps or lanterns to bother with.

Think what a help and convenience Electric Power and Light will be to you on the farm if you make it the Northern Electric way.

The system is entirely automatic; not even a button to press. No complicated parts or unnecessary frills to get out of order. Built for real hard work and long service with economy of upkeep. As simple and easy to look after as the Northern Electric Telephone you know so well.

NORTHERN ELECTRIC POWER and LIGHT is guaranteed absolutely reliable. Plenty of power; plenty of light. Progressive farmers all over Canada are buying the Northern Electric system because of its honest dollar-for-dollar value.

There is a Northern Electric system for every requirement. All types, all sizes, either direct connected or belt driven, operating from 15 to 1000 lights or their equivalent in power for farm work.

May we send you some interesting illustrated leaflets? You are not obligated in any way. Fill in and return coupon today
